J. G. H.	Joseph G. Horner, A.M.I.Mech.E. Author of *Plating and Boiler-Making*; *Practical Metal-Turning*; &c.	**Tool.**
J. G. M.	John Gray M'Kendrick, M.D., LL.D., F.R.S., F.R.S. (Edin.). Emeritus Professor of Physiology in the University of Glasgow. Professor of Physiology, 1876–1906. Author of *Life in Motion*; *Life of Helmholtz*; &c.	**Touch; Vascular System:** *History of Discovery.*
J. H. H.	John Henry Hessels, M.A. Author of *Gutenberg: an Historical Investigation.*	**Typography:** *History.*
J H. M.	John Henry Middleton, M.A., Litt.D., F.S.A., D.C.L. (1846–1896). Slade Professor of Fine Art in the University of Cambridge, 1886–1895. Director of the Fitzwilliam Museum, Cambridge, 1889–1892. Art Director of the South Kensington Museum, 1892–1896. Author of *The Engraved Gems of Classical Times*; *Illuminated Manuscripts in Classical and Mediaeval Times.*	**Verona** (*in part*); **Verrocchio, Andrea del; Vesta** (*in part*).
J. H. R.	John Horace Round, M.A., LL.D. Balliol College, Oxford. Author of *Feudal England*; *Studies in Peerage and Family History*; *Peerage and Pedigree*,	**Vere** (*Family*).
J. J. T.	Sir Joseph John Thomson, F.Sc., LL.D., Ph.D., F.R.S. Cavendish Professor of Experimental Physics and Fellow of Trinity College, Cambridge. President of the British Association, 1909–1910. Author of *A Treatise on the Motion of Vortex Rings*; *Application of Dynamics to Physics and Chemistry*; *Recent Researches in Electricity and Magnetism*; &c.	**Vacuum Tube.**
J. L.*	Sir Joseph Larmor, M.A., D.Sc., LL.D., F.R.S. Fellow of St John's College, Cambridge, and Lucasian Professor of Mathematics in the University. Secretary of the Royal Society. Professor of Natural Philosophy, Queen's College, Galway, 1880–1885. Author of *Ether and Matter*, and various memoirs on Mathematics and Physics.	**Units, Dimensions of.**
J. L. E. D	John Louis Emil Dreyer. Director of Armagh Observatory. Author of *Planetary Systems from Thales to Kepler*; &c.	**Transit Circle.**
J. L. W.	Jessie Laidlay Weston. Author of *Arthurian Romances unrepresented in Malory.*	**Tristan.**
J. O.	Josiah Oldfield, M.A., D.C.L., M.R.C.S., L.R.C.P. Barrister-at-law. Senior Physician of the Lady Margaret Fruitarian Hospital, Bromley. Author of *Myrrh and Amaranth*; *The Voice of Nature*; &c.	**Vegetarianism.**
J. O. B.	John Oliver Borley, M.A. Gonville and Caius College, Cambridge.	**Trawling, Seining and Netting.**
J. P.-B.	James George Joseph Penderel-Brodhurst. Editor of the *Guardian*, London.	**Vernis, Martin.**
J. P. Pe	Rev. John Punnett Peters, Ph.D., D.D. Canon Residentiary, Protestant Episcopal Cathedral of St John the Divine in New York City. Formerly Professor of Hebrew, University of Pennsylvania. In charge of the Expedition of the University of Pennsylvania to Nippur, 1888–1895. Author of *Scriptures, Hebrew and Christian*; *Nippur, or Explorations and Adventures on the Euphrates*; &c.	**Ur.**

J. So.	John Southward. Author of *A Dictionary of Typography and its Accessory Arts*; *Practical Printing*; &c.	**Typography:** *Modern Practical Typography* (*in part*).
J. S. F.	John Smith Flett, D.Sc., F.G.S. Petrographer to the Geological Survey. Formerly Lecturer on Petrology in Edinburgh University. Neill Medallist of the Royal Society of Edinburgh. Bigsby Medallist of the Geological Society of London.	**Tonalite; Trachyte; Tuff; Variolites; Veins** (*Geology*).
J. S. N.	Joseph Shield Nicholson, M.A., Sc.D. Professor of Political Economy at Edinburgh University. Fellow of the British Academy. Author of *Principles of Political Economy*; *Money and Monetary Problems*; &c.	**Usury; Value.**
J. S. R.	James Smith Reid, M.A., LL.D., Litt.D. Professor of Ancient History and Fellow and Tutor of Gonville and Caius College, Cambridge. Hon. Fellow, formerly Fellow and Lecturer of Christ's College. Browne's and Chancellor's Medals. Editor of editions of Cicero's *Academia*; *De Amicitia*; &c.	**Trajan; Tribune; Varro, Marcus Terentius.**
J. T. Be.	John Thomas Bealby. Joint-author of Stanford's Europe. Formerly Editor of the *Scottish Geographical Magazine*. Translator of Sven Hedin's *Through Asia*, *Central Asia and Tibet*; &c.	**Transbaikalia** (*in part*); **Transcaspian Region** (*in part*); **Turgai** (*in part*); **Turkestan** (*in part*); **Ufa** (*Government*) (*in part*); **Ural Mountains** (*in part*).
J. W.	James Williams, M.A., D.C.L., LL.D. All Souls Reader in Roman Law in the University of Oxford, and Fellow of Lincoln College. Author of *Wills and Succession*; &c.	**Torture.**
J. W. He.	James Wycliffe Headlam, M.A. Staff Inspector of Secondary Schools under the Board of Education, London. Formerly Fellow of King's College, Cambridge. Professor of Greek and Ancient History at Queen's College, London. Author of *Bismarck and the Foundation of the German Empire*; &c.	**Treitschke, Heinrich von.**
J. W. J.	Jeremiah Whipple Jenks. See the biographical article: Jenks, Jeremiah Whipple.	**Trusts.**
K. S.	Kathleen Schlesinger. Editor of *The Portfolio of Musical Archaeology*. Author of *The Instruments of the Orchestra*.	**Trigonon; Tromba Marina; Trombone** (*in part*); **Trumpet** (*in part*); **Tuba; Valves.**
L. C.*	Louis Courtauld, M.A., M.R.C.S., L.R.C.P. Formerly Research Scholar, Middlesex Hospital Cancer Laboratories. Author of *Life-History of Pneumococcus*; &c.	**Tumour.**
L. Du.	Louis Duncan, Ph.D., M.Am.Inst.E.E. Late Associate Professor of Applied Electricity at the Johns Hopkins University, Baltimore, Md. Head of the Department of Electrical Engineering, Massachusetts Institute of Technology.	**Traction.**
L. E. H.	Leonard Erskine Hill, F.R.S., M.R.C.S., L.R.C.P. Lecturer on Physiology at the London Hospital. Formerly Demonstrator of Physiology in the University of Oxford; and Assistant Professor of Physiology, University College, London. Author of *Manual of Physiology*; &c.	**Vascular System:** *Physiology*.
L. J.*	Lionel James, F.R.G.S. *The Times* Special Correspondent in South Africa, 1899–1901. Reuter's Special Correspondent in the Chitral Campaign, 1894–1895. Author of *With the Chitral Relief Force*; *On the Heels of De Wet*; &c. &c.	**Transvaal:** *History* (*in part*).
L. J. S.	Leonard James Spencer, M.A. Assistant in the Department of Mineralogy, British Museum. Formerly Scholar of Sidney Sussex College, Cambridge, and Harkness Scholar. Editor of the *Mineralogical Magazine*.	**Torbernite; Tremolite; Tridymite; Vanadinite; Vesuvianite.**
L. V.*	Luigi Villari. Italian Foreign Office (Emigration Department). Formerly Newspaper Correspondent in the east of Europe. Italian Vice-Consul in New Orleans, 1906; Philadelphia, 1907; and Boston, 1907–1910. Author of *Italian Life in Town and Country*; &c.	**Tuscany:** *History*; **Vespers, Sicilian.**
M. Br.	Margaret Bryant.	**Tourneur, Cyril:** *Introduction and Bibliography*.
M. G.	Moses Gaster, Ph.D. Chief Rabbi of the Sephardic Communities of England. Vice-President, Zionist Congress, 1898, 1899, 1900. Ilchester Lecturer at Oxford on Slavonic and Byzantine Literature, 1886 and 1891. Author of *A New Hebrew Fragment of Ben-Sira*; *The Hebrew Version of the Secretum Secretorum of Aristotle*.	**Vacarescu.**
M. N. T.	Marcus Niebuhr Tod, M.A. Fellow and Tutor of Oriel College, Oxford. University Lecturer in Epigraphy. Joint-author of *Catalogue of the Sparta Museum*.	**Vaphio.**
M. O. B. C.	Maximilian Otto Bismarck Caspari, M.A. Reader in Ancient History at London University. Lecturer in Greek at Birmingham University, 1905–1908.	**Trachis; Umbria** (*Ancient*).
N. D. M.	Newton Dennison Mereness, A.M., Ph.D. Author of *Maryland as a Proprietary Province*.	**United States:** *Fauna and Flora*.

O. Ba.	OSWALD BARRON, F.S.A. Editor of the *Ancestor*, 1902–1905. Hon. Genealogist to Standing Council of the Honourable Society of the Baronetage.	**Tournament;** **Tudor** *(Family).*
P. A. K.	PRINCE PETER ALEXEIVITCH KROPOTKIN. See the biographical article: KROPOTKIN, PRINCE P. A.	**Transbaikalia** *(in part);* **Transcaspian Region** *(in part);* **Turgai** *(in part);* **Turkestan** *(in part);* **Ufa** *(Government) (in part);* **Ural Mountains** *(in part).*
P. C. M.	PETER CHALMERS MITCHELL, M.A., F.R.S., F.Z.S., D.Sc., LL.D. Secretary of the Zoological Society of London. University Demonstrator in Comparative Anatomy and Assistant to Linacre Professor at Oxford, 1888–1891. Author of *Outlines of Biology*; &c.	**Variation and Selection;** **Vertebrata.**
P. C. Y.	PHILIP CHESNEY YORKE, M.A. Magdalen College, Oxford. Editor of *Letters of Princess Elizabeth of England.*	**Vane, Sir H.**
P. Gi.	PETER GILES, M.A., LL.D., LITT.D. Fellow and Classical Lecturer of Emmanuel College, Cambridge, and University Reader in Comparative Philology. Formerly Secretary of the Cambridge Philological Society.	**U.** **V.**

R. I. P.	REGINALD INNES POCOCK, F.Z.S. Superintendent of the Zoological Gardens, London.	**Trilobites.**
R. J. M.	RONALD JOHN MCNEILL, M.A. Christ Church, Oxford. Barrister-at-law. Formerly Editor of the *St James's Gazette* (London).	**Tone, Theobald Wolfe;** **Tyler, Wat;** **Ulster, Earls of.**
R. K. D.	SIR ROBERT KENNAWAY DOUGLAS. Formerly Keeper of Oriental Printed Books and MSS. at the British Museum; and Professor of Chinese, King's College, London. Author of *The Language and Literature of China*; &c.	**Tsēng Kuo-fan.**
R. L.*	RICHARD LYDEKKER, M.A., F.R.S., F.G.S., F.Z.S. Member of the Staff of the Geological Survey of India, 1874–1882. Author of *Catalogues of Fossil Mammals, Reptiles and Birds in the British Museum*; *The Deer of All Lands*; *The Game Animals of Africa*; &c.	**Toxodontia;** **Tylopoda;** **Ungulata.**
R. N. B.	ROBERT NISBET BAIN (d. 1909). Assistant Librarian, British Museum, 1883–1909. Author of *Scandinavia: the Political History of Denmark, Norway and Sweden, 1513–1900*; *The First Romanovs, 1613–1725*; *Slavonic Europe: the Political History of Poland and Russia from 1469 to 1796*; &c.	**Torkenskjold, Peder;** **Torstensson, Count;** **Valdemar I., II. and IV. of Denmark;** **Verboczy, Istvan.**
R. P. S.	R. PHENÉ SPIERS, F.S.A., F.R.I.B.A. Formerly Master of the Architectural School, Royal Academy, London. Past President of Architectural Association. Associate and Fellow of King's College, London. Corresponding Member of the Institute of France. Editor of *Fergusson's History of Architecture.* Author of *Architecture: East and West*; &c.	**Tower;** **Tracery;** **Triumphal Arch;** **Vault.**
R. S. C.	ROBERT SEYMOUR CONWAY, M.A., D.LITT. (Cantab.). Professor of Latin and Indo-European Philology in the University of Manchester. Formerly Professor of Latin in University College, Cardiff; and Fellow of Gonville and Caius College, Cambridge. Author of *The Italic Dialects.*	**Veneti;** **Vestini.**
R. Tr.	ROLAND TRUSLOVE, M.A. Fellow, Dean and Lecturer in Classics at Worcester College, Oxford.	**Troyes.**
S. A. C.	STANLEY ARTHUR COOKE, M.A. Editor for the Palestine Exploration Fund. Lecturer in Hebrew and Syriac, and formerly Fellow, Gonville and Caius College, Cambridge. Examiner in Hebrew and Aramaic, London University, 1904–1908. Author of *Glossary of Aramaic Inscriptions*; *The Laws of Moses and the Code of Hammurabi*; *Critical Notes on Old Testament History*; *Religion of Ancient Palestine*; &c.	**Tree-Worship;** **Uzziah.**

S. M. C.	SYDNEY MONCKTON COPEMAN, M.A., M.D., F.R.C.P., M.R.C.S., F.R.S. Medical Inspector to H.M. Local Government Board, London. Medical Lecturer on Public Health at Westminster Hospital. Lt.-Col. and Divisional Sanitary Officer, 1st London Division, Territorial Force. Milroy Lecturer, Royal College of Physicians, London, 1898. Author of *Vaccination, its Natural History and Pathology*; &c.	**Vaccination.**
S. M. E.-W.	SIR SYDNEY MAROW EARDLEY-WILMOT. Rear-Admiral (retired). Commanded H.M.S. "Dolphin" in Red Sea, 1885–1886, and assisted in the defence of Suakin. Superintendent of Ordnance Stores, 1902–1909. Author of *Life of Vice-Admiral Lord Lyons*; *Our Navy for a Thousand Years*; &c.	**Torpedo.**
S. N.	SIMON NEWCOMB, LL.D., D.Sc. See the biographical article: NEWCOMB, SIMON.	**Uranus** (*Astronomy*). **Venus** (*Astronomy*).
T. As.	THOMAS ASHBY, M.A., D.LITT. Director of the British School of Archaeology at Rome. Formerly Scholar of Christ Church, Oxford. Craven Fellow, 1897. Conington Prizeman, 1906. Member of the Imperial German Archaeological Institute. Author of *The Classical Topography of the Roman Campagna.*	**Tortona; Trapani; Trasimene, Lake; Trebula; Turin; Turris Libisonis; Tuscany:** *Geography*; **Tusculum; Tyndaris; Udine; Umbria** (*Modern*); **Valeria Via; Varia; Vasto; Veii; Veleia; Velia; Velletri; Venafrum; Venusia; Vercelli; Verona** (*in part*); **Vesuvius** (*in part*).
T. A. A.	THOMAS ANDREW ARCHER, M.A. Author of *The Crusade of Richard I.*; &c.	**Ursula, St** (*in part*).
T. A. I.	THOMAS ALLAN INGRAM, M.A., LL.D. Trinity College, Dublin.	**Unemployment; Vagrancy.**
T. C. C.	THOMAS CHROWDER CHAMBERLIN, A.M., PH.D., LL.D., SC.D., F.G.S., F.A.A.S., &c. Professor and Head of Department of Geology and Director of the Walker Museum, University of Chicago. Investigator of Fundamental Problems of Geology at the Carnegie Institute. Consulting Geologist, United States and Wisconsin Geological Survey. Author of *Geology of Wisconsin*; *General Treatise on Geology* (with R. D. Salisbury); &c.	**United States:** *Geology* (*in part*).
T. E. H.	THOMAS ERSKINE HOLLAND, M.A., D.C.L., LL.D., K.C. Fellow of the British Academy. Fellow of All Souls College, Oxford. Professor of International Law and Diplomacy in the University of Oxford, 1874–1910. Bencher of Lincoln's Inn. Author of *Studies in International Law*; *The Elements of Jurisprudence*; *Alberici Gentilis de jure belli*; *The Laws of War on Land*; *Neutral Duties in a Maritime War*; &c.	**Treaties; Vacarius.**
T. F. C.	THEODORE FREYLINGHUYSEN COLLIER, PH.D. Assistant Professor of History, Williams College, Williamstown, Mass.	**Urban VII. and VIII.**
T. H.	THOMAS HODGKIN, D.C.L., LITT.D. See the biographical article: HODGKIN, THOMAS.	**Vandals** (*in part*).
T. S.	THE RIGHT HONOURABLE LORD SHAW OF DUNFERMLINE. Lord of Appeal. M.P. for Hawick District, 1892–1909. Lord Advocate for Scotland, 1905–1909.	**Vergniaud, Pierre.**
T. Se.	THOMAS SECCOMBE, M.A. Balliol College, Oxford. Lecturer in History, East London and Birkbeck Colleges, University of London. Stanhope Prizeman, Oxford, 1887. Assistant Editor of *Dictionary of National Biography*, 1891–1901. Author of *The Age of Johnson*; &c.	**Vanbrugh, Sir John.**
V. C.*	SIR VINCENT HENRY PENALVER CAILLARD. Director of Vickers, Sons & Maxim, Ltd.; and the London, Chatham & Dover Railway. Formerly President of the Ottoman Public Debt Council, and Financial Representative of England, Holland and Belgium in Constantinople. Author of *Imperial Fiscal Reform.*	**Turkey:** *Geography and Statistics.*
V. M.	VICTOR CHARLES MAHILLON. Principal of the Conservatoire Royal de Musique at Brussels. Chevalier of the Legion of Honour.	**Trombone** (*in part*); **Trumpet** (*in part*).
W. A. B. C.	REV. WILLIAM AUGUSTUS BREVOORT COOLIDGE, M.A., F.R.G.S. Fellow of Magdalen College, Oxford. Professor of English History, St David's College, Lampeter, 1880–1881. Author of *Guide to Switzerland*; *The Alps in Nature and in History*; &c. Editor of the *Alpine Journal*, 1880–1889.	**Töpffer, Rodolphe; Trent; Tschudi; Unterwalden; Uri; Valais; Var; Vaud.**
W. A. He.	WILLIAM ABBOT HERDMAN, D.Sc., F.R.S. Professor of Natural History in the University of Liverpool. President of the Linnean Society, 1904. Author of *Report upon the Tunicata collected during the Voyage of the "Challenger"*; &c.	**Tunicata.**
W. A. P.	WALTER ALISON PHILLIPS, M.A. Formerly Exhibitioner of Merton College and Senior Scholar of St John's College, Oxford. Author of *Modern Europe*; &c.	**Utrecht:** *Province* (*in part*); **Valet; Vavassor; Verona, Congress of; Vestments.**
W. Bo.	WILHELM BOUSSET, D.TH. Professor of New Testament Exegesis in the University of Göttingen. Author of *Das Wesen der Religion*; *The Antichrist Legend*; &c.	**Valentinus and the Valentinians.**

W. E. G.	SIR WILLIAM EDMUND GARSTIN, G.C.M.G. Governing Director, Suez Canal Co. Formerly Inspector-General of Irrigation, Egypt, and Adviser to the Ministry of Public Works in Egypt.	**Tsana** (*in part*).
W. F. C.	WILLIAM FEILDEN CRAIES, M.A. Barrister-at-Law, Inner Temple. Lecturer on Criminal Law, King's College, London. Editor of Archbold's *Criminal Pleading* (23rd edition).	**Trade Marks** (*in part*); **Treason; Trial; Venue.**
W. G.*	WALCOT GIBSON, D.Sc., F.G.S. Geologist on H.M. Geological Survey. Author of *The Gold-bearing Rocks of the S. Transvaal*; *Mineral Wealth of Africa*; *The Geology of Coal and Coal Mining*; &c.	**Transvaal:** *Geology.*

ENCYCLOPÆDIA BRITANNICA

ELEVENTH EDITION

VOLUME XXVII

TONALITE, in petrology, a rock of the diorite class, first described from Monte Adamello near Tonale in the Eastern Alps. It may be described as a quartz-diorite containing biotite and hornblende in nearly equal proportions. The principal felspar is plagioclase, but orthoclase occurs also, usually in small amount. Those varieties which are rich in orthoclase, in addition to plagioclase, have been called quartz-monzonites or adamellites, but a better term is grano-diorite, which has been very generally adopted in America for rocks which are intermediate in character between the granites and the diorites. The hornblende of the diorites is green, sometimes with a tinge of brown; the biotite is always brown and strongly pleochroic. Often these two minerals are clustered together irregularly or in parallel growths. They have generally a fairly strong tendency to idiomorphism, but may sometimes enclose plagioclase felspar in ophitic manner. Both of them decompose to chlorite, epidote and carbonates. The plagioclase felspar, which may form more than one-half of the rock, is andesine or oligoclase; simple crystals are rare, the majority being complex growths with centres of felspar rich in lime, while in the external zones the proportion of soda felspar increases greatly. The inner portions have often well-defined, but very irregular, boundaries, and are sometimes sponge-like, with the cavities filled up with a later, more acid, deposit. This seems to indicate that growth has taken place in stages, alternating with periods when the crystallized felspar was eroded or partly dissolved. The orthoclase sometimes forms irregular plates enclosing individuals of plagioclase. Quartz occurs both in irregular simple grains and as micropegmatite. Occasionally pale green pyroxene is visible in the centre of crystals of dark green hornblende. The accessory minerals apatite, magnetite and zircon are always present, and very common also are orthite in coffee-coloured zonal prisms practically always encircled by yellow epidote, and reddish-brown crystals of sphene, simple or twinned.

In external appearance the tonalites are very like the granites but usually darker in colour. Tonalite-porphyrites often accompany them, having the same composition but with phenocrysts of felspar, quartz, hornblende and biotite in a fine-grained ground-mass. Veins and threads of fine grey rock, mainly composed of quartz and felspar, often intersect tonalite-masses and have been called tonalite-aplites, seeing that they bear the same relations to aplites as the aplites do to the granites. They contain more soda-lime felspar than the normal aplites. Towards their margins the larger alpine masses of tonalite often assume banded or gneissic facies, due apparently to movement during intrusion.

In eastern Tirol another tonalite occurs at Rieserferner; there is also a well-known mass of this rock near Traversella. In the south of Scotland (Galloway district) tonalites accompany hornblende- and biotite-granites, hornblende- and augite-diorites. The newer granites of the Highlands of Scotland in many places pass into tonalites, especially near their margins, and similar rocks occur in Ireland in a few places. Grano-diorites have been described from California, and rocks of very similar character occur in the Andes, Patagonia and the lesser Antilles. Tonalites are also said to be frequent among the igneous rocks of Alaska. (J. S. F.)

TONAWANDA, a city of Erie county, New York, U.S.A., about 11 m. by rail N. of Buffalo on the Niagara River at the mouth of Tonawanda Creek (opposite North Tonawanda), and on the Erie Canal. Pop. (1900), 7421, of whom 1834 were foreign-born; (1910 census), 8290. Tonawanda is served by the New York Central & Hudson River and the Erie railways, and is connected with Buffalo, Niagara Falls and Lockport by electric lines. The industries depend chiefly on electric power generated by the Niagara Falls, 11 m. distant. There are rolling-mills, planing-mills, ship-yards, and blast-furnaces, and among the manufactures are wooden ware, flour and paper. The surrounding region was the scene of hostilities during the Seven Years' War, and the War of 1812. The first permanent white settlement was made about 1809, and Tonawanda was incorporated as a village in 1854 and was chartered as a city in 1903. The name of the city is an Indian word said to mean "swift water."

TONBRIDGE [Tunbridge], a market town in the Tonbridge or south-western parliamentary division of Kent, England, 29½ m. S.S.E. of London by the South Eastern & Chatham railway. Pop. of urban district (1901), 12,736. It is situated on rising ground above the river Medway, which is crossed by a stone bridge erected in 1775. The church of St Peter and St Paul, chiefly Decorated and Perpendicular, with some portions of earlier date, was completely restored in 1879. There are remains of an ancient castle, consisting chiefly of a finely preserved gateway, of the Early Decorated period, flanked by two round towers. The castle was formerly defended by three moats, one of them formed by the Medway. Tonbridge School was founded by Sir Andrew Judd, lord mayor of London in the time of Edward VI., and was rebuilt in 1865, remodelled in 1880, and extended subsequently. Ornamental articles of inlaid wood, called Tonbridge ware, chiefly sold at Tunbridge Wells, are largely manufactured. There are gunpowder mills on the banks of the Medway, and wool-stapling, brewing and tanning are carried on. There is some traffic on the Medway, which is navigable for barges.

Tonbridge owed its early importance to the castle built by Richard, earl of Clare, in the reign of Henry I. The castle was besieged by William Rufus, was taken by John in the wars with the barons, and again by Prince Edward, son of Henry III. After being in the possession of the earls of Clare and Hertford, and of the earls of Gloucester, it became the property of the Staffords, and on the attainder of the duke of Buckingham in the reign of Henry VIII. was taken by the Crown. It was dismantled during the Civil War. The lords of the castle had the right of attending the archbishops of Canterbury on state occasions as chief butlers.

TONDERN, a town of Germany, in the Prussian province of Schleswig-Holstein, on the Widane, 8 m. from the North Sea at Hoyer, opposite the island of Sylt, and 42 m. by rail N.W. from Flensburg. Pop. (1900), 4244. Tondern was in early days a seaport, but since the reclamation of the marshes and the dredging of the Widane navigation has ceased, and vessels load and unload at Hoyer, with which the place has direct railway communication. The trade consists chiefly in agricultural produce and cattle, and there is an important horse market.

In the village of Galhus, lying about 4 m. N., were discovered, in 1639 and 1734 respectively, two golden horns of the Scandinavian period; these were stolen in 1802 from the Museum of Northern Antiquities in Copenhagen, where they had been treasured, and have never been recovered.

See Karstens, *Die Stadt Tondern* (Tondern, 1861).

TONE, THEOBALD WOLFE (1763–1798), Irish rebel, the son of Peter Tone, a Dublin coachmaker, was born in Dublin on the 20th of June 1763. His grandfather was a small farmer in county Kildare, and his mother was the daughter of a captain in the merchant service. Though entered as a student at Trinity College, Dublin, Tone gave little attention to study, his inclination being for a military career; but after eloping with Matilda Witherington, a girl of sixteen, he took his degree in 1786, and read law in London at the Middle Temple and afterwards in Dublin, being called to the Irish bar in 1789. Though idle, Tone had considerable ability. Chagrined at finding no notice taken of a wild scheme for founding a military colony in the South Seas which he had submitted to Pitt, he turned to Irish politics. An able pamphlet attacking the administration of the marquess of Buckingham in 1790 brought him to the notice of the Whig club; and in September 1791 he wrote a remarkable essay over the signature "A Northern Whig," of which 10,000 copies are said to have been sold. The principles of the French Revolution were at this time being eagerly embraced in Ireland, especially among the Presbyterians of Ulster, and two months before the appearance of Tone's essay a great meeting had been held in Belfast, where republican toasts had been drunk with enthusiasm, and a resolution in favour of the abolition of religious disqualifications had given the first sign of political sympathy between the Roman Catholics and the Protestant dissenters of the north. The essay of "A Northern Whig" emphasized the growing breach between the Whig patriots like Flood and Grattan, who aimed at Catholic emancipation and parliamentary reform without disloyalty to the connexion with England, and the men who desired to establish a separate Irish republic. Tone expressed in his pamphlet unqualified contempt for the constitution which Grattan had so triumphantly extorted from the English government in 1782; and, himself a Protestant, he urged co-operation between the different religious sects in Ireland as the only means of obtaining complete redress of Irish grievances.

In October 1791 Tone converted these ideas into practical policy by founding, in conjunction with Thomas Russell (1767–1803), Napper Tandy (*q.v.*) and others, the society of the "United Irishmen." The original purpose of this society was no more than the formation of a political union between Roman Catholics and Protestants, with a view to obtaining a liberal measure of parliamentary reform; it was only when that object appeared to be unattainable by constitutional methods that the majority of the members adopted the more uncompromising opinions which Wolfe Tone held from the first, and conspired to establish an Irish republic by armed rebellion. Tone himself admitted that with him hatred of England had always been "rather an instinct than a principle," though until his views should become more generally accepted in Ireland he was prepared to work for reform as distinguished from revolution. But he desired to root out the popular respect for the names of Charlemont and Grattan, and to transfer to more violent leaders the conduct of the national movement. Grattan was a reformer and a patriot without a tincture of democratic ideas; Wolfe Tone was a revolutionary whose principles were drawn from the French Convention. Grattan's political philosophy was allied to that of Edmund Burke; Tone was a disciple of Danton and Thomas Paine.

Democratic principles were gaining ground among the Roman Catholics as well as the Presbyterians. A quarrel between the moderate and the more advanced sections of the Roman Catholic Committee led, in December 1791, to the secession of sixty-eight of the former, led by Lord Kenmare; and the direction of the committee then passed to more violent leaders, of whom the most prominent was John Keogh, a Dublin tradesman. The active participation of the Roman Catholics in the movement of the United Irishmen was strengthened by the appointment of Tone as paid secretary of the Roman Catholic Committee in the spring of 1792. When the legality of the Roman Catholic Convention in 1792 was called in question by the government, Tone drew up for the committee a statement of the case on which a favourable opinion of counsel was obtained; and a sum of £1500 with a gold medal was voted to Tone by the Convention when it dissolved itself in April 1793. Burke and Grattan were anxious that provision should be made for the education of Irish Roman Catholic priests at home, to preserve them from the contagion of Jacobinism in France; Wolfe Tone, "with an incomparably juster forecast," as Lecky observes, "advocated the same measure for exactly opposite reasons." He rejoiced that the breaking up of the French schools by the revolution had rendered necessary the foundation of Maynooth College, which he foresaw would draw the sympathies of the clergy into more democratic channels. In 1794 the United Irishmen, persuaded that their scheme of universal suffrage and equal electoral districts was not likely to be accepted by any party in the Irish parliament, began to found their hopes on a French invasion. An English clergyman named William Jackson, a man of infamous notoriety who had long lived in France, where he had imbibed revolutionary opinions, came to Ireland to nogotiate between the French committee of public safety and the United Irishmen. For this emissary Tone drew up a memorandum on the state of Ireland, which he described as ripe for revolution; the paper was betrayed to the government by an attorney named Cockayne to whom Jackson had imprudently disclosed his mission; and in April 1794 Jackson was arrested on a charge of treason. Several of the leading United Irishmen, including Reynolds and Hamilton Rowan, immediately fled the country; the papers of the United Irishmen were seized; and for a time the organization was broken up. Tone, who had not attended meetings of the society since May 1793, remained in Ireland till after the trial and suicide of Jackson in April 1795. Having friends among the government party, including members of the Beresford family, he was enabled to make terms with the government, and in return for information as to what had passed between Jackson, Rowan and himself he was permitted to emigrate to America, where he arrived in May 1795. Taking up his residence at Philadelphia, he wrote a few months later to Thomas Russell expressing unqualified dislike of the American people, whom he was disappointed to find no more truly democratic in sentiment and no less attached to order and authority than the English; he described George Washington as a "high-flying aristocrat," and he found the aristocracy of money in America still less to his liking than the European aristocracy of birth.

Tone did not feel himself bound in honour by his compact with the government at home to abstain from further conspiracy; and finding himself at Philadelphia in the congenial company of Reynolds, Rowan and Napper Tandy, he undertook a mission to Paris to persuade the French government to send an expedition to invade Ireland. In February 1796 he arrived in Paris and had interviews with De La Croix and L. N. M. Carnot, who were greatly impressed by his energy, sincerity and ability. A commission was given him as adjutant-general in the French army, which he hoped might protect him from the penalty of treason in the event of capture by the English; though he himself claimed the authorship of a proclamation said to have been issued by the United Irishmen, enjoining that all Irishmen taken with arms in their hands in the British service should be instantly shot; and he supported a project for landing a thousand criminals in England, who were to be commissioned to burn Bristol and commit any other atrocity in their power. He drew up two memorials representing that the landing of a considerable French force in Ireland would be followed by a general rising of the people, and giving a detailed account of the condition of the country. The French directory, which possessed information from Lord Edward Fitzgerald (*q.v.*) and Arthur O'Connor confirming Tone, prepared to despatch an expedition under Hoche. On the 15th of December 1796 the expedition, consisting of forty-three sail and carrying about 15,000 men with a large supply of war material for distribution in Ireland, sailed from Brest. Tone, who accompanied it as "Adjutant-general Smith," had the greatest contempt for the seamanship of the French sailors, which was amply justified by the disastrous result of the invasion. Returning to France without having effected anything, Tone served for some months in the French army under Hoche; and in June 1797 he took part in preparations for a Dutch expedition to Ireland, which was to be supported by the French. But the Dutch fleet was detained in the Texel for many weeks by unfavourable weather, and before it eventually put to sea in October, only to be crushed by Duncan in the battle of Camperdown, Tone had returned to Paris; and Hoche, the chief hope of the United Irishmen, was dead. Bonaparte, with whom Tone had several interviews about this time, was much less disposed than Hoche had been to undertake in earnest an Irish expedition; and when the rebellion broke out in Ireland in 1798 he had started for Egypt. When, therefore, Tone urged the directory to send effective assistance to the Irish rebels, all that could be promised was a number of small raids to descend simultaneously on different points of the Irish coast. One of these under Humbert succeeded in landing a force in Killala Bay, and gained some success in Connaught before it was subdued by Lake and Cornwallis, Wolfe Tone's brother Matthew being captured, tried by court-martial, and hanged; a second, accompanied by Napper Tandy (*q.v.*), came to disaster on the coast of Donegal; while Wolfe Tone took part in a third, under Admiral Bompard, with General Hardy in command of a force of about 3000 men, which encountered an English squadron near Lough Swilly on the 12th of October 1798. Tone, who was on board the "Hoche," refused Bompard's offer of escape in a frigate before the action, and was taken prisoner when the "Hoche" was forced to surrender. When the prisoners were landed a fortnight later Sir George Hill recognized Tone in the French adjutant-general's uniform. At his trial by court-martial in Dublin, Tone made a manly straightforward speech, avowing his determined hostility to England and his design "by fair and open war to procure the separation of the two countries," and pleading in virtue of his status as a French officer to die by the musket instead of the rope. He was, however, sentenced to be hanged on the 12th of November; but on the 11th he cut his throat with a penknife, and on the 19th of November 1798 he died of the wound.

Although Wolfe Tone had none of the attributes of greatness, "he rises," says Lecky, "far above the dreary level of commonplace which Irish conspiracy in general presents. The tawdry and exaggerated rhetoric; the petty vanity and jealousies; the weak sentimentalism; the utter incapacity for proportioning means to ends, and for grasping the stern realities of things, which so commonly disfigure the lives and conduct even of the more honest members of his class, were wholly alien to his nature. His judgment of men and things was keen, lucid and masculine, and he was alike prompt in decision and brave in action." In his later years he overcame the drunkenness that was habitual to him in youth; he developed seriousness of character and unselfish devotion to what he believed was the cause of patriotism; and he won the respect of men of high character and capacity in France and Holland. His journals, which were written for his family and intimate friends, give a singularly interesting and vivid picture of life in Paris in the time of the directory. They were published after his death by his son, William Theobald Wolfe Tone (1791–1828), who was educated by the French government and served with some distinction in the armies of Napoleon, emigrating after Waterloo to America, where he died, in New York City, on the 10th of October 1828.

See *Life of Theobald Wolfe Tone by himself, continued by his son, with his political writings*, edited by W. T. Wolfe Tone (2 vols., Washington, 1826), another edition of which is entitled *Autobiography of Theobald Wolfe Tone*, edited with introduction by R. Barry O'Brien (2 vols., London, 1893); R. R. Madden, *Lives of the United Irishmen* (7 vols., London, 1842); Alfred Webb, *Compendium of Irish Biography* (Dublin, 1878); W. E. H. Lecky, *History of Ireland in the Eighteenth Century*, vols. iii., iv., v. (cabinet ed., 5 vols., London, 1892). (R. J. M.)

TONGA, or Friendly Islands (so called by Captain Cook), an archipelago in the South Pacific Ocean, about 350 m. S.S.W. of Samoa and 250 m. E.S.E. of Fiji. The long chain of islands, numbering about 150, though with a collective land area of only 385 sq. m., extends from 18° 5′ to 22° 29′ S. and 174° to 176° 10′ W., and is broken into three groups, viz. the Tonga to the south, Hapai (which again is divided into three clusters) in the centre and Vavau to the north. The largest island is Tongatabu (the Sacred Tonga, Tasman's Amsterdam) in the southern group, measuring about 25 by 10 m., and 165 sq. m. in area, which contains the capital, Nukualofa. The vegetation is rich and beautiful, but the scenery tame, the land seldom rising above 60 ft.; Eua (Tasman's Middelburg), 9 m. south-east and 67 sq. m. in area, is 1078 ft. in extreme height, and much more picturesque, being diversified by rocks and woods. Vavau, in the northern group, is 55 sq. m. in extent and 300 ft. high. Next to these come the coral islands Nomuka and Lifuka in the Hapai group; Tofua, 2846 ft., Late or Lette, 1800 ft. and Kao, 3020 ft. high, which are volcanic and smaller. The numerous islets of the central group are very fertile. It is along the western side of the northern half of the chain that the line of volcanic action is apparent; the islands here (of which some are active volcanoes) are lofty. To the east the whole chain is bounded by a profound trough in the ocean bed, which extends southwestward, east of the Kermadec Islands, towards New Zealand. The majority of the Tonga Islands, however, are level, averaging 40 ft. high, with hills rising to 600 ft.; their sides are generally steep. The surface is covered with a rich mould unusual in coral islands, mixed towards the sea with sand, and having a substratum of red or blue clay. The soil is thus very productive, although water is scarce and bad. Barrier reefs are rare; fringing reefs are numerous, except on the east side, which is nearly free, and there are many small isolated reefs and volcanic banks among the islands. If the reefs impede navigation they form some good harbours. The best is on the south-western side of Vavau; another is on the north of Tongatabu. Earthquakes are not infrequent. From 1845 to 1857 volcanic eruptions were very violent, and islands once fertile were devastated and nearly destroyed. A new island rose from the sea, and was at once named "Wesley," but disappeared again. In 1886 there was a serious volcanic eruption in the outlying island of Niuafoou, and at the same time Falcon Reef, normally awash at high water, discharged sufficient scoriae and pumice to form a new island 50 ft. high. In 1898 the island had been washed away, but in 1900 H.M.S. "Porpoise" found that a solid core of black rock had been extruded 6 ft. above high water. All the volcanoes in the group were then quiescent.

Geology.—The line of volcanic action extends along the western side of the northern half of the chain. Some of the islands are built of volcanic rocks alone; such are Hongu-tonga and Hongu-hapai, which appear to be fragments of a single ancient crater, Tofua, Kao, Late, Metis, Amargua and Falcon Island. The lava is a basic augite-andesite. Another group of islands consists of elevated masses of submarine volcanic deposits, upon some of which coral-reef limestone forms a more or less complete covering; such are Tonumeia and the Nomuka group (Mango, Tonua, Nomuka-iki). All the volcanic rocks of these islands are submarine stratified tuffs which are penetrated here and there by andesite or diabase dikes. The Vavau group consists entirely of coral limestone, which is occasionally crystalline, and contains stalactitic caves of great beauty.

Climate, Flora, Fauna.—The climate is healthy for Europeans, being dry and cool as compared with that of Samoa and Fiji. There are frequent alternations of temperature, which averages 75° to 77° F., though considerably higher in the wet season. Cool south-east trade winds blow, sometimes with great violence, from April to December. During the rest of the year the winds blow from west-north-west and north, with rain and occasional destructive hurricanes. A cyclone which devastated Vavau in April 1900 was the most destructive ever recorded in the group, but hurricanes are rare. The average rainfall for the year is about 80 ins. The vegetation is similar to that of Fiji, but more definitely Indo-Malayan in character; it embraces all the plants of the groups to the east with many that are absent there. Ferns abound, some of them peculiar, and tree ferns on the higher islands, and all the usual fruit trees and cultivated plants of the Pacific are found. There are several kinds of valuable timber trees. The only indigenous land mammalia are a small rat and a few curious species of bats. The dog and the pig were no doubt introduced by man. Of birds some 30 kinds are known, an owl being the only bird of prey; parrots, pigeons, kingfishers, honey-suckers, rails, ducks, and other water birds are numerous. There are snakes and small lizards, but no frogs or toads. Of insects there are relatively few kinds; but ants, beetles and mosquitoes abound. The fishes, of an Indo-Malay type, are varied and numerous. Turtle and sea-snakes abound, as do mollusca, of which a few are peculiar, and zoophytes.

Inhabitants.—The population of the archipelago is about 19,000, of whom about 370 are whites or half-castes. The natives, a branch of the Polynesian race, are the most progressive and most intellectual in the Pacific Islands, except the Hawaiians. They have exercised an influence over distant neighbours, especially in Fiji, quite out of proportion to their numbers. Their conquests have extended as far as Niué, or Savage Island, 200 m. east, and to various other islands to the north. In Captain Cook's time Poulaho, the principal chief, considered Samoa to be within his dominions. This pre-eminence may perhaps be due to an early infusion of Fijian blood: it has been observed that such crosses are always more vigorous than the pure races in these islands; and this influence seems also traceable in the Tongan dialect, and appears to have been partially transmitted thence to the Samoan. Various customs, traditions and names of places also point to a former relation with Fiji. Their prior conversion to Christianity gave the Tongans material as well as moral advantages over their neighbours. Crime is infrequent, and morality, always above the Polynesian average, has improved. The people have strict notions of etiquette and gradations of rank. In disposition they are amiable and courteous, but arrogant, lively, inquisitive and inclined to steal—their attacks in earlier days on Europeans, when not caused by misunderstandings, being due probably to their coveting property which to them was of immense value. They are brave and not unenergetic, though the soft climate and the abundance of food discourage industry. They value children, and seldom practised infanticide, and cannibalism was rare. Their women are kindly treated, and only do the lighter work. Agriculture, which is well understood, is the chief industry. They are bold and skilful sailors and fishermen; other trades, as boat and house building, carving, cooking, net and mat making, are usually hereditary. Their houses are slightly built, but the surrounding ground and roads are laid out with great care and taste.

There were formerly (till the early 18th century) two sovereigns; the higher of these, called Tui Tonga (chief of Tonga), was greatly reverenced but enjoyed little power. The real ruler and the chief officers of the state were members of the Tubou family, from which also the wife of the Tui Tonga was always chosen, whose descendants through the female line had special honours and privileges, under the title of *tamaha*, recalling the *vasu* of Fiji. The explanation of the dual kingship is probably this—the Tui Tonga were regarded as the direct descendants of the original head of the family from which the people sprang; regarded with reverence, and possessing unlimited power, they came to misuse this and discontent resulted, whereupon, to protect themselves, they appointed an executive deputy. Below these came the Eiki or chiefs, and next to them the class called Matabule. These were the hereditary counsellors and companions of the chiefs, and conveyed to the people the decisions formed at their assemblies. They also directed the national ceremonies, and preserved the popular traditions. While, under the control of Europeans, the Tongans have shown some aptitude for administration, they fail when left to themselves. They pick up superficial acquirements with astonishing ease, but seem to be incapable of mastering any subject. They write shorthand, but speak no English; they have a smattering of higher mathematics, yet are ignorant of book-keeping. Their government, effective enough when dealing with natives, breaks down in all departments concerned with Europeans, and becomes the prey of designing traders. Their ambition is to rank as a civilized state, and the flattery lavished on them by their teachers has spoiled them.

There are some ancient stone remains in Tongatabu, burial places (*feitoka*) built with great blocks, and a remarkable monument consisting of two large upright blocks morticed to carry a transverse one, on which was formerly a circular basin of stone.

Administration and Trade.—In May 1900 the group became a British protectorate under the native flag, the appointment of the consul and agent being transferred to the government of New Zealand. In 1904 the financial and legal administration was put into the hands of the British High Commissioner for the Western Pacific. The native king is assisted by a legislative assembly consisting, in equal numbers, of hereditary nobles and popular (elected) representatives. The wisdom of King George Tubou in refusing to alienate an acre of land, except upon lease, has resulted in Tonga having been the last native state in the Pacific to lose its independence. There is a revenue of about £21,000 annually derived chiefly from a poll-tax, leases and customs. The principal exports are copra, bananas, oranges and fungus, and the annual values of exports and imports are £80,000 and £70,000 respectively on an average, though both fluctuate considerably. British coin is legal tender (since 1905). There are five churches in Tonga—the Free Wesleyans, embracing the great majority of the inhabitants, Wesleyans, Roman Catholics, and Seventh Day Adventists. These last are few; a still smaller number of natives are nominally Anglicans.

History.—In 1616 the vessels of Jacob Lemaire and Willem Cornelis Schouten reached the island of Niuatobutabu, and had a hostile encounter with the natives. In 1643 Abel Tasman arrived at Tongatabu and was more fortunate. The next visit was that of Samuel Wallis in 1767, followed in 1773 by that of Captain Cook. In 1777 Cook returned, and stayed seven weeks among the islands. In 1799 a revolution, having its origin in jealousy between two natives of high rank, broke out. Civil war dragged on for many years—long after the deaths of the first leaders—but Taufaahau, who became king in 1845 under the name of George Tubou I., proved a strong ruler. In 1822 a Methodist missionary had arrived in the island, and others followed. The attempt to introduce a new faith led to renewed strife, this time between converts and pagans, but King George (who fully appreciated the value of intercourse with foreigners) supported the missionaries, and by 1852 the rebels were subdued. The missionaries, finding their position secure, presently began to take action in political affairs, and persuaded the king to grant a constitution to the Tongans, who welcomed it with a kind of childish enthusiasm, but were far from fitted to receive it. A triennial parliament, a cabinet, a privy council, and an elaborate judicial system were established, and the cumbrous machinery was placed in the hands of a "prime minister," a retired Wesleyan missionary, Mr Shirley Baker. Treaties of friendship were concluded with Germany, Great Britain, and the United States of America. Baker induced the king to break off his connexion with the Wesleyan body in Sydney, and to set up a state church. Persecution of members of the old church followed, and in 1890 the missionary-premier had to be removed from the group by the high commissioner. He afterwards returned to initiate a new sect called the "Free Church of England," which for a time created further divisions among the people.

King George Tubou died in 1893 at the age of ninety-six, and was succeeded by his great-grandson under the same title.

Mr Basil Thomson (who after Baker's deportation had carried out reforms which the natives, when left alone, were incapable of maintaining) was sent in 1900 to conclude the treaty by which the king placed his kingdom under British protection.

See Captain Cook's *Voyages* and other early narratives; Martin, *Mariner's account of the Tonga Islands* (Edinburgh, 1827); Vason, *Four Years in Tongatabu* (London, 1815); A. Monfort, *Les Tonga, ou Archipel des Amis* (Lyons, 1893); B. H. Thomson, *The Diversions of a Prime Minister* (London, 1894).

TONGKING,[1] a province of French Indo-China, and protectorate of France, situated between 20° and 23½° N. and 102° and 108½° E., and bounded N. by the Chinese provinces of Kwang-Tung, Kwang-Si and Yun-nan, W. by Laos, S. by Annam, and E. by the Gulf of Tongking. Area, about 46,000 sq. m. The population is estimated at 6,000,000, including 33,000 Chinese and about 4000 Europeans. Geographically, Tongking comprises three regions: (1) the delta of the Song-Koi (Red river), which, beginning at Son-Tay and coalescing with the delta of the Thai-Binh, widens out into the low-lying and fertile plain within which are situated the principal cities. (2) Two mountainous tracts, to the north and west of the delta, running approximately from north-west to south-east, one separating the basins of the Song-Koi and the Canton river, the other those of the Song-Koi and the Mekong. (3) A region of plateaus and low hills forming a transition between the delta and the mountains. The main geographical feature in the country is the Song-Koi, which, taking its rise near Tali Fu, in Yun-nan, enters Tongking at Lao-Kay (the Lao boundary), and flows thence in a south-easterly direction to the Gulf of Tongking. It was this river which mainly, in the first instance, attracted the French to Tongking, as it was believed by the explorers that, forming the shortest route by water to the rich province of Yun-nan, it would prove also to be the most convenient and expeditious means of transporting the tin, copper, silver and gold which are known to abound there. This belief, however, has proved fallacious. The upper course of the stream is constantly impeded by rapids, the lowest being about thirty miles above Hung-Hoa. Beyond Lao-Kay navigation is impracticable during the dry season, and at all other times of the year goods have to be there transferred into light junks. Below Lao-Kay larger junks, and in the summer months steam launches of shallow draught use the river. Within the limits of Yun-nan the navigation is still more difficult. Near Son-Tay the Song-Koi receives the waters of the Song-Bo (Black river) and the Song-Ka (Clear river), parallel affluents rising in Yun-nan, and from that point divides into a network of waterways which empty themselves by countless outlets into the sea. The Song-Cau rises in north-eastern Tongking and below the town of Sept Pagodes, where it is joined by the Song-Thuong to form the Thai-Binh, divides into numerous branches, communicating with the Song-Koi by the Canal des Rapides and the Canal des Bambous.

The coast line of Tongking from Mon-Kay on the Chinese frontier to Thanh-Hoa, near that of Annam, has a length of 375 m. From Mon-Kay as far as the estuary of the Song-Koi it is broken, rugged and fringed with islands and rocky islets. The bay of Tien-Hien, to the south of which lies the island of Ke-Bao, and the picturesque bay of Along, are the chief indentations. Beyond the island of Cac-Ba, south of the Bay of Along, the coast is low, flat and marshy, and tends to advance as the alluvial deposits of the delta accumulate.

The climate of Tongking is less trying to Europeans than that of the rest of French Indo-China. During June, July and August, the temperature ranges between 82° and 100° F., but from October to May the weather is cool. The country is subject to typhoons in August and September.

In the wooded regions of the mountains the tiger, elephant and panther are found, and wild buffalo, deer and monkeys are common. The delta is the home of ducks and many other varieties of aquatic birds. Tea, cardamom, and mulberry grow wild, and in general the flora approximate to that of southern China.

The Annamese (see ANNAM), who form the bulk of the population of Tongking, are of a somewhat better physique than those of the rest of Indo-China. Savage tribes inhabit the northern districts—the Muongs the mountains bordering the Black river, the Thôs the regions bordering the Clear river and the Thai-Binh. The Muongs are bigger and stronger than the Annamese. They have square foreheads, large faces and prominent cheek-bones, and their eyes are often almost straight.

Rice, which in some places furnishes two crops annually, is incomparably the most important product of the delta. Elsewhere there are plantations of coffee, tobacco, ramie, paper-tree (*Daphne odora*), cotton, jute, sugar-cane, pepper and mulberry. The cultivation of silkworms is of growing importance.

Gold, copper, tin, lead and other metals are found in the higher regions of Tongking, but only gold and tin are exploited, and these only to a very limited extent. There is a large output of coal of inferior quality from Hon-Gay on the bay of Along and there are coal-workings on the island of Ke-Bao.

Hanoi, Hai-phong and Nam-Dinh carry on cotton-spinning, and Hanoi and Nam-Dinh are well known for the manufacture of carved and inlaid furniture. The natives are skilful at enamelling and the chasing and ornamentation of gold and other metals. The manufacture of paper from the fibrous bark of the paper-tree is a widespread industry and there are numerous distilleries of rice-spirit.

The imports of Tongking, which in 1905 reached a value of £3,501,422, comprise railway material, cereals, flour, liquors, woven goods, petroleum, glassware, paper, prepared skins, clocks and watches, arms and ammunition, &c. Exports (valued at £1,393,674 in 1905) comprise rice, rubber, manila hemp, ramie, lacquer and badian oils, raw skins, silk-waste, coal, Chinese drugs, rattan, mats, gamboge.

The transit trade via Tongking between Hong-Kong and the province of Yun-nan in southern China is of considerable importance, reaching in 1905 a value of £1,146,000. This trade is entirely in the hands of Chinese houses, the tin of the Yun-nan mines and cotton yarns from Hong-Kong constituting its most important elements. Goods in transit enjoy a rebate of 80% of the customs duties. Goods are carried on the Song-Koi to Lao-Kay or Man-Hao, thence on mules. The waterways of the delta are lined with embankments, the causeways along which form the chief means of land communication of the region. (For railways, see INDO-CHINA, FRENCH.)

The protectorate of Tongking approaches nearer to direct administration than that of Annam, where the conditions of the protectorate are more closely observed. Till 1897 the emperor of Annam was represented in Tongking by a viceroy (*kinh-luoc*), but now the native officials are appointed by and are directly under the control of the resident-superior, who resides at Hanoi, presides over the protectorate council, and is the chief territorial representative of France. Tongking is divided into nineteen provinces, in each of which there is a resident or a vice-resident, and four military territories, the latter administered by commandants. In each province there is a council of native "notables," elected by natives and occupied with the discussion of the provincial budget and public works. There is also a deliberative council of natives (instituted 1907) for the whole of Tongking. The provincial administration, local government and educational system are analogous to those of Annam (*q.v.*). Two chambers of the court of appeal of Indo-China and a criminal court sit at Hanoi; there are tribunals of first instance and tribunals of commerce at Hanoi and Hai-Phong. When both parties to a suit are Annamese, it comes within the jurisdiction of the *An-Sat* or native judge of the province.

The following is a summary of the budgets of 1899 and 1904:—

	Receipts.	Expenditure.
	£	£
1899	461,235	427,993
1904	756,648	494,034

The chief source of revenue is the direct taxes (including especially the poll-tax and land-tax), which amounted in 1904 to £417,723, while the chief items of expenditure are the cost of the residencies and general staff, public works and the civil guard.

For the early history of Tongking, see ANNAM and INDO-CHINA, FRENCH. Tongking was loosely united to Annam until 1801, when Gia-long, king of Annam, brought it definitely under his sway. Having, by the treaty of 1862 and the annexation of Cochin China, firmly established themselves in Annamese territory, the French began to turn their attention to Tongking, attracted by the reported richness of its mineral wealth. They found a pretext for interfering in its affairs in the disturbances arising from the invasion of its northern provinces by the disbanded followers of the Taiping rebels. The Franco-German War of 1870–71 put an end to the project for a time, but the return of peace in Europe was the signal for the renewal of hostilities in the East. The appearance of Garnier's work on his expedition up the Mekong again aroused an interest in Tongking,

[1] See also INDO-CHINA, FRENCH, and ANNAM.

and the reported wealth of the country added the powerful motive of self-interest to the yearnings of patriotism. Already Jean Dupuis, a trader who in the pursuit of his calling had penetrated into Yun-nan, was attempting to negotiate for the passage up the Song-Koi of himself and a cargo of military stores for the Chinese authorities in Yun-nan. Meanwhile Captain Senez appeared from Saigon, having received instructions to open the route to French commerce. But to neither the trader nor the naval officer would the Tongkingese lend a favourable ear, and in default of official permission Dupuis determined to force his way up the river. This he succeeded in doing, but arrived too late, for he found the Taiping rebellion crushed and the stores no longer wanted.

On the return of Dupuis to Hanoi, the Tongkingese general at that place wrote to the king of Annam, begging him to induce the governor of Cochin-China to remove the intruder. An order was thereupon issued calling upon Dupuis to leave the country. This he declined to do, and, after some negotiations, Francis Garnier with a detachment was sent to Hanoi to do the best he could in the difficult circumstances. Garnier threw himself heart and soul into Dupuis's projects, and, when the Tongkingese authorities refused to treat with him except on the subject of Dupuis's expulsion, he attacked the citadel in November, 1873, and carried it by assault. Having thus secured his position, he sent to Saigon for reinforcements, and meanwhile sent small detachments against the five other important fortresses in the delta (Hung-yen, Phu-Ly, Hai-Duong, Ninh-Binh and Nam-Dinh), and captured them all. The Tongkingese now called in the help of Lu-Vinh-Phuoc, the leader of the "Black Flags,"[1] who at once marched with a large force to the scene of action. Within a few days he recaptured several villages near Hanoi, and so threatening did his attitude appear that Garnier, who had hurried back after capturing Nam-Dinh, made a sortie from the citadel. The movement proved a disastrous one, and resulted in the death of Garnier and of his second in command, Balny d'Avricourt.

Meanwhile the news of Garnier's hostilities had alarmed the governor of Saigon, who, having no desire to be plunged into a war, sent Philastre, an inspector of native affairs, to offer apologies to the king of Annam. When, however, on arriving in Tongking Philastre heard of Garnier's death, he took command of the French forces, and at once ordered the evacuation of Nam-Dinh, Ninh-Binh and Hai-Duong—a measure which, however advantageous it may have been to the French at the moment, was most disastrous to the native Christian population, the withdrawal of the French being the signal for a general massacre of the converts. In pursuance of the same policy Philastre made a convention with the authorities (March, 1874) by which he bound his countrymen to withdraw from the occupation of the country, retaining only the right to trade on the Song-Koi and at Hanoi and Hai-Phong, and agreed to put an end to Dupuis's aggressive action.

For a time affairs remained *in statu quo*, but in 1882 Le Myre de Villers, the governor of Cochin-China, sent Henri Rivière with a small force to open up the route to Yun-nan by the Song-Koi. With a curious similarity the events of Garnier's campaign were repeated. Finding the authorities intractable, Rivière stormed and carried the citadel of Hanoi, and then, with very slight loss, he captured Nam-Dinh, Hai-Duong, and other towns in the delta. And once again these victories brought the Black Flags into the neighbourhood of Hanoi. As Garnier had done, so Rivière hurried back from Nam-Dinh on news of the threatened danger. Like Garnier also he headed a sortie against his enemies, and like Garnier he fell a victim to his own impetuosity (May, 1883).

In the meantime the Annamese court had been seeking to enlist the help of the Chinese in their contest with the French. The tie which bound the tributary nation to the sovereign state had been for many generations slackened or drawn closer as circumstances determined, but it had never been entirely dissevered, and from the Annamese point of view this was one of the occasions when it was of paramount importance that it should be acknowledged and acted upon. With much more than usual regularity, therefore, the king despatched presents and letters to the court of Peking, and in 1880 he sent a special embassy, loaded with unusually costly offerings, and bearing a letter in which his position of a tributary was emphatically asserted. Far from ignoring the responsibility thrust upon him, the emperor of China ordered the publication of the letter in the *Peking Gazette*.

The death of Rivière and the defeat of his troops had placed the French in a position of extreme difficulty. M. Jules Ferry, who had become premier of France in February 1883, determined on a vigorous forward policy. But for the moment the outlying garrisons, except those of Nam-Dinh and Hai-Phong, had to be withdrawn and Hanoi itself was besieged by the Black Flags. Reinforcements brought by Admiral Courbet and General Bouet were insufficient to do more than keep them at bay. So continued was the pressure on the garrison that Bouet determined to make an advance upon Son-Tay to relieve the blockade. He attacked Vong, a fortified village, but he met with such resistance that, after suffering considerable loss, he was obliged to retreat to Hanoi. In the lower delta fortune sided with the French, and almost without a casualty Hai-Duong and Phu-Binh fell into their hands. Meanwhile, in order to put more effective pressure upon the court of Hué, Dr Harmand, commissary-general, supported by Courbet, proceeded with a naval force to the Hué river. They found that, though King Tu Duc was dead, his policy of resistance was maintained, and therefore stormed the city. After a feeble defence it was taken, and Harmand concluded a treaty with the king (August 1883) in which the French protectorate was fully recognized, the king further binding himself to recall the Annamese troops serving in Tongking, and to construct a road from Saigon to Hanoi.

Though this treaty was exacted from Annam under pressure, the French lost no time in carrying out that part of it which gave them the authority to protect Tongking, and Bouet again advanced in the direction of Son-Tay. But again the resistance he met with compelled him to retreat, after capturing the fortified post of Palan. Meanwhile, on the determination to attack Son-Tay becoming known in Paris, the Chinese ambassador warned the ministry that, since Chinese troops formed part of the garrison, he should consider it as tantamount to a declaration of war. But his protest met with no consideration. On the arrival of reinforcements an advance was again made; and on the 16th of December 1883, after some desperate fighting, Son-Tay fell.

During 1884 the French made themselves masters of the lower delta. Throughout the campaign Chinese regulars fought against the French, who thus found themselves involved in war with China. While hostilities were in progress M. Fournier, the French consul at Tientsin, had been negotiating for peace, so far as China was concerned, with Li Hung-chang, and in May 1884 had signed and sealed a memorandum by which the Chinese plenipotentiary agreed that the Chinese troops should evacuate the northern provinces of Tongking "*immédiatement.*" In the following month another treaty, signed at Hué, confirmed the French protectorate over Annam and Tongking. It was not, however, followed by a cessation of military operations. A misunderstanding arose between the French and the Chinese as to the exact date for the evacuation of their posts by the Chinese, and in June General Millot, then commander-in-chief of the French forces, dispatched Colonel Dugenne at the head of a strong force to occupy Lang-Son. The expedition was badly arranged; the baggage train was far too unwieldy; and the pace at which the men were made to march was too quick for that scorching time of the year. They advanced, however, to Bac-Le, within 25 m. of Lang-Son, when they suddenly came upon a Chinese camp. An irregular engagement began, and, in the pitched battle which ensued, the Chinese broke the French lines, and drove them away in headlong flight. This brought the military operations for the season to a close.

During the rainy season fevers of all kinds became alarmingly

[1] Bands of Chinese rebels who infested the mountainous region of Tongking.

prevalent, and the number of deaths and of men invalided was very large. In the meantime, however, an expedition, led by Colonel Donnier, against the Chinese garrison at Chu, about 10 m. south-east from Lang-kep, was completely successful; and in a battle fought near Chu the Chinese were defeated, with a loss of 3000 killed, the French loss being only 20 killed and 90 wounded. In the skirmishes which followed the French were generally victorious, but not to such a degree as to warrant any enlargement of the campaign.

In January 1885 large reinforcements arrived and Brière de l'Isle, who had succeeded Millot as commander-in-chief, ordered an advance towards Lang-Son. The difficulties of transport greatly impeded his movements, still the expedition was successful. On the 6th of February three forts at Dong-Song, with large supplies of stores and ammunition, fell into the hands of the French. Three days' heavy fighting made them masters of a defile on the road, and on the 13th Lang-Son was taken, the garrison having evacuated the town just before the entrance of the conquerors. With his usual energy General Négrier, who commanded a division under Brière de l'Isle, pressed on in pursuit to Ki-Hea, and even captured the frontier town of Cua-Ai. But Brière de l'Isle had now to hurry back to the relief of Tuyen-Kwan, which was doggedly resisting the attacks of an overwhelming Chinese force, and Négrier was left in command at Lang-Son. The withdrawal of Brière de l'Isle's division gave the Chinese greater confidence, and, though for a time Négrier was able to hold his own, on the 22nd and 23rd of March he sustained a severe check between Lang-Son and That-Ke, which was finally converted into a complete rout, his troops being obliged to retreat precipitately through Lang-Son to Than-Moi and Dong-Song. Brière de l'Isle reached Tuyen-Kwan, the garrison of which was commanded by Colonel Dominé, on the 3rd of March, and effected its relief. The disaster at Lang-Son caused the downfall of the Ferry ministry (March 30). Shortly afterwards Sir Robert Hart succeeded in negotiating peace with China. By the terms agreed on at Tientsin (June, 1885), it was stipulated that France was to take Tongking and Annam under its protection and to evacuate Formosa and the Pescadores. (For further history, see INDO-CHINA.)

TONGS (O. Eng. *tange*, M. Eng. *tonge*, cf. Du. *tang*, Ger. *Zange*, from base *tang*, to bite, cf. Gr. *δάκνειν*), a gripping and lifting instrument, of which there are many forms adapted to their specific use. Some are merely large pincers or nippers, but the greatest number fall into three classes: the first, as in the common fire-tongs, used for picking up pieces of coal and placing them on a fire, which have long arms terminating in small flat circular grippers and are pivoted close to the handle; the second, as in the sugar-tongs, asparagus tongs, and the like, consisting of a single band of metal bent round or of two bands joined at the head by a spring, and third, such as the blacksmith's tongs or the crucible-tongs, in which the pivot or joint is placed close to the gripping ends. A special form of tongs is that known as the "lazy-tongs," consisting of a pair of grippers at the end of a series of levers pivoted together like scissors, the whole being closed or extended by the movement of the handles communicated to the first set of levers and thence to the grippers, the whole forming an extensible pair of tongs for gripping and lifting things at a distance.

TONGUE (O. Eng. *tunge*), in anatomy, a movable organ situated in the floor of the mouth, and serving for the sensation of taste besides helping in the mastication of food, in articulate speech, and in feeling the exact position of any structure within the mouth.

The tongue is divided into a main part or body, a base which looks backward toward the pharynx, a dorsum or upper surface, a root by which it is attached to the hyoid bone and floor of the mouth, a tip which is free and an inferior free surface in contact with the front part of the floor of the mouth and with the lower incisor teeth. Owing to the large amount of muscle in its composition the shape of the tongue varies considerably from time to time. The dorsum of the tongue is covered by stratified squamous epithelium, and, when at rest, is convex both antero-posteriorly and transversely; it is thickly studded with papillae, of which four kinds are recognized.

Filiform papillae are minute conical projections covering the whole of the dorsum, by which term the true upper surface is meant, as well as the tip and borders of the tongue. They are very numerous and contain a short core of subepithelial mucous membrane covered by a thick coating of epithelial cells, which coating may divide at its tip into a number of thread-like processes.

Fungiform papillae are less numerous than the last, and somewhat resemble "button mushrooms"; they generally contain special taste buds.

Circumvallate papillae are usually from seven to ten in number and are arranged in the form of a V, the apex of which points down the throat. They lie quite at the back of the upper surface of the tongue and each consists of a little flat central mound surrounded by a deep moat, the outer wall of which is slightly raised above the surface, and it is to this that the papillae owe their name. Both sides of the moat have taste buds embedded in them, while into the bottom small serous glands open.

Foliate papillae are only vestigial in man and consist of a series of vertical ridges occupying a small oval area on each side of the tongue near its base and just in front of the attachment of the anterior pillars of the fauces. (See PHARYNX.)

The posterior surface or base of the tongue forms part of the anterior wall of the pharynx and has a quite different appearance to that of the dorsum. On it are found numerous circular or oval elevations of the mucous membrane caused by lymphoid tissue (lymphoid follicles), on the summit of the most of which is a mucous crypt or depression. The division between the superior or oral surface of the tongue and the posterior or pharyngeal is sharply marked by a V-shaped shallow groove called the *sulcus terminalis* which lies just behind and parallel to the V-shaped row of circumvallate papillae. At the apex of this V is a small blind pit, the *foramen caecum.*

At the lower part of the pharyngeal surface three folds of mucous membrane, called *glosso-epiglottic folds*, run backward; the middle one passes to the centre of the front of the epiglottis, while the two lateral ones, in modern anatomy often called pharyngo-epiglottic folds, pass backward and outward to the fossa of the tonsil.

On the inferior free surface of the tongue, that is to say, the surface which is seen when the mouth is looked into and the tongue turned up, there is a median fold of mucous membrane called the *fraenum linguae*, which is attached below to the floor of the mouth. On each side of this the blue outlines of the ranine veins are seen, while close to these a little fold on each side, known as a *plica fimbriata*, is often found. It must not, however, be confused with the plica sublingualis described in the article MOUTH AND SALIVARY GLANDS.

The substance of the tongue is composed almost entirely of striped muscle fibres which run in different directions. Some of these bundles, such as the *superficial, deep, transverse* and *oblique linguales* are confined to the tongue and are spoken of as intrinsic muscles. Other muscles, such as the hyo-glossus, stylo-glossus, &c. come from elsewhere and are extrinsic; these are noticed under the head of MUSCULAR SYSTEM. The arteries of the tongue are derived from the lingual, a branch of the external carotid (see ARTERIES), while the veins from the tongue return the blood, by one or more veins on each side, into the internal jugular vein (see VEINS).

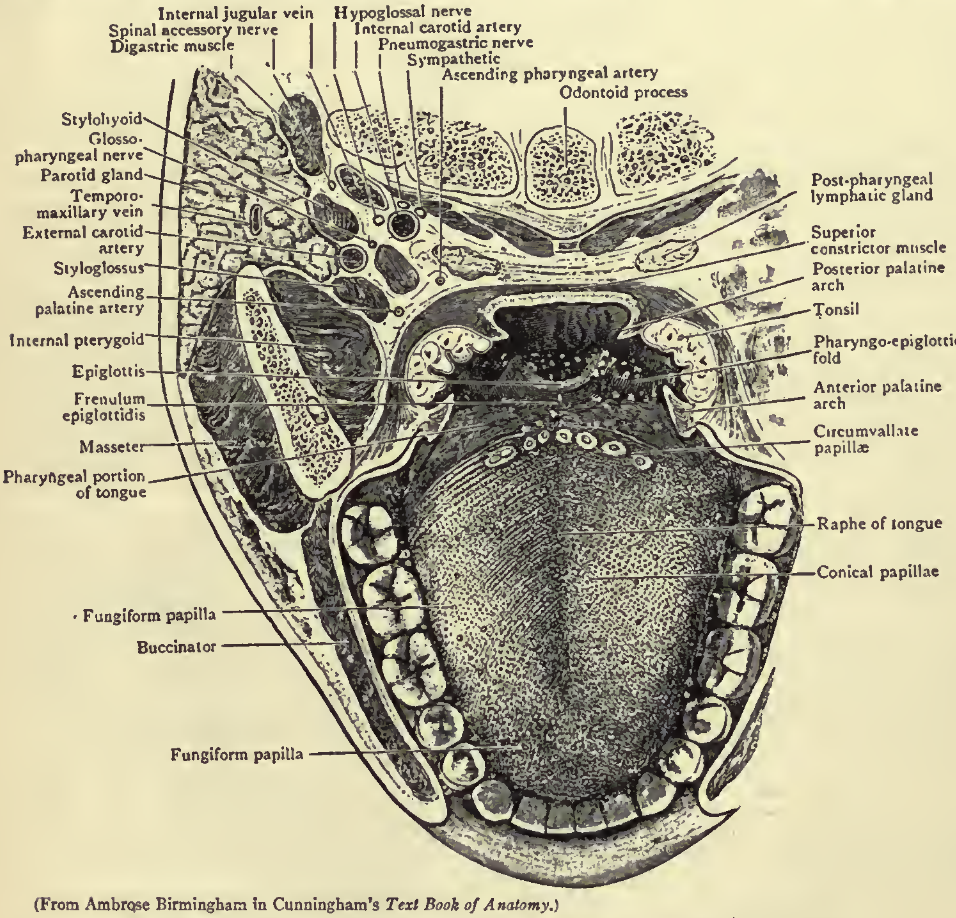
The nerves to the tongue are the (1) *lingual* or gustatory, a branch of the fifth (see NERVES: *Cranial*) which supplies the anterior two-thirds with ordinary sensation and also, by means of the chorda tymphani which is bound up with it, with taste sensation; (2) the glossopharyngeal which supplies the circumvallate papillae and posterior third of the tongue with taste and ordinary sensation; (3) a few twigs of the superior laryngeal branch of the vagus to the pharyngeal surface of the tongue; and (4) the hypoglossal which is the motor nerve to the muscles.

Embryology.

The mucous membrane covering the second and third visceral arches fuses to form the furcula (see RESPIRATORY SYSTEM). Just in front of this a rounded eminence appears at an early date in the ventral wall of the pharynx to form the *tuberculum impar* which is separated from the furcula by the depression known as the *sinus arcuatus.* This tuberculum impar gradually grows to form the central part of the tongue in front of the foramen cæcum, while the anterior part of the organ is derived from two lateral swellings which appear in the floor of the mouth and surround the tuberculum impar antero-laterally. The posterior third, or pharyngeal part, is developed from the anterior part of the furcula in the middle line, that is to say from the third visceral arch. The sinus arcuatus becomes gradually shallower as these two parts of the tongue grow together and eventually is indicated by the *sulcus terminalis;* in the mid line, however, the isthmus of the thyroid grows down from it, forming the *thyro-glossal duct* the remains of which are seen in the foramen caecum (see DUCTLESS GLANDS). It will be seen that the tongue is developed in connexion with the first, second and third visceral arches, and it is therefore to be expected that the fifth, seventh and ninth nerves which supply those arches would help to supply it, but the vagus from the fourth arch reaches it in addition, while the fact that most of the muscular substance of the tongue is supplied by the hypoglossal nerve is explained on the theory that some of the cervical skeletal musculature has grown cephalad into the tongue and has carried its nerve with it.

Comparative Anatomy.

The tongue is present in fishes but it is an immovable swelling in the floor of the mouth and is practically devoid of muscles. In the hag (*Myxine*) among the Cyclostomata, and pike (*Esox*) among the



(From Ambrose Birmingham in Cunningham's *Text Book of Anatomy.*)

Horizontal Section through Mouth and Pharynx at the Level of the Tonsils.

Teleostei, teeth are developed on the tongue. In the Amphibia the tailed forms (Urodela) usually have tongues like fishes, though in the genus Spelerpes the organ is very free and can be protruded for a great distance. In the majority of the Anura the tongue is usually attached close to the front of the floor of the mouth so that it can be flapped forward with great rapidity. There are, however, two closely allied families of frogs (Xenopodidae and Pipidae) which form the order of Aglossa, because in them the tongue is suppressed.

In the reptiles the tongue is generally very movable, though this is not the case in the Crocodilia and many of the Chelonia. The forked tongues of snakes and many lizards and the highly specialized telescopic tongue of the chameleon are familiar objects.

In birds the tongue is usually covered with horny epithelium and is poorly supplied with muscles. When it is very protrusible, as in the woodpecker, the movement is due to the hyoid, with the base of the tongue attached, moving forward.

In the Mammalia the tongue is always movable by means of well-developed extrinsic and intrinsic muscles, while papillae and glands are numerous. The filiform papillae reach their maximum in the feline family of the Carnivora where they convert the tongue into a rasp by which bones can be licked clean of all flesh attached to them.

Foliate papillae are best seen in the rodents, and when they are well developed the circumvallate papillae are few, often only one on each side.

In the lemurs an under tongue or *sub lingua* is found, which is probably represented by the *plicae fimbriatae* under the human tongue, and by some morphologists is regarded as the homologue of the whole tongue of the lower vertebrates, the greater part of the mammalian tongue being then looked upon as a new formation.

Anat. der Wirbelthiere* (Leipzig, 1901); A. Oppel, *Lehrb. vergleich. mikroskop. Anat. der Wirbelthiere*, Teil 3 (Jena, 1900); Parker and Haswell, *Text Book of Zoology* (London, 1897). (F. G. P.)

Surgery of the Tongue.

During infancy it is sometimes noticed that the little band of membrane (*fraenum*) which binds the under part of the tongue to the middle line of the floor of the mouth is unusually short. The condition will probably right itself as the front part of the tongue takes on its natural growth. In some children the tongue is so large that it hangs out of the mouth, scratching itself upon the teeth. This condition is likely to be associated with weak intellect.

Acute inflammation of the tongue may be caused by the sting of a wasp or by the entrance of septic germs through a wound, and the trouble may end in an abscess.

Chronic inflammation of the tongue may be caused by syphilis, by the irritation of decayed teeth or of a badly-fitting plate of artificial teeth, or by excessive smoking. The condition is one of danger in that it may lead eventually to the tongue becoming the seat of cancer. The treatment demands the removal of every source of irritation. The teeth must be made sound and smooth and must be kept so. Smoking must be absolutely and entirely given up, and salt, mustard, pickles, spirits, aerated waters, and everything else which is likely to be a cause of irritation must be avoided.

Cancer of the tongue is the result of chronic irritation which produces an excessive growth of the scaly covering of the tongue and causes an invasion of the deeper parts of the tongue by the scales. It is more often found in men than women and is usually associated with a hard swelling at one side of the tongue—perhaps near a jagged tooth or at the spot where the end of the pipe-stem approaches the tongue. The nerves of the tongue being caught and compressed in the growth, pain is constant and severe, and the movements during mastication cause great distress. The swelling gradually increases in size and, spreading to the floor of the mouth, hinders the free movements of the tongue. In due course it breaks down in the middle and a hard-walled ulcer appears. All this time the small scales of the cancer are finding their way along the lymph-channels and causing a secondary enlargement in the glands just below the jaw and along the side of the neck. Enlargement of the cervical glands is a very serious complication of cancer of the tongue.

The only treatment for cancer of the tongue which is at present known in surgery is the early removal by operation. It not seldom happens that because there is a certain amount of doubt as to the exact nature of the growth in the early weeks delay in operating is reasonably permitted, but during this time there is the risk of the cells of the disease finding their way to the lymphatic system. Still, inasmuch as there may be great difficulty in determining the diagnosis from tertiary syphilitic disease, a course of treatment by iodide of potassium may well be recommended. Syphilis is often the precursor of lingual cancer, and it is impossible to say exactly when the syphilitic lesion becomes malignant. In the case of a cancerous tumour of the tongue being so deeply or so widely attached that its removal cannot be recommended, relief may be afforded by the extraction of most, or all of the teeth, by limiting the food to the most simple and unirritating kinds, and possibly by dividing the great sensory nerves of the tongue.

Cancer of the tongue is now operated on in advanced cases such as in former years would not have been dealt with by a radical operation. An incision is made beneath the jaw and through the floor of the mouth, by which the tongue is drawn out and rendered easily accessible, the arteries being leisurely secured as the tissues are cut across. The upper part of the gullet is plugged by a sponge so that no blood can enter the lungs, and unimpeded respiration is provided for by the preliminary introduction of a tube into the windpipe. Through the incision which is made below the jaw the infected lymphatic glands are removed. To Dr Kocher of Berne the profession and the public are indebted for this important advance in the treatment of this disease. (E. O*.)

TONGUES, GIFT OF, or GLOSSOLALIA (γλῶσσα, tongue, λαλεῖν, speak), a faculty of abnormal and inarticulate vocal utterance, under stress of religious excitement, which was widely developed in the early Christian circles, and has its parallels in other religions. In the New Testament such experiences are recorded in Caesarea (Acts x. 46), at Corinth (Acts xix. 6; 1 Cor. xii., xiv.), Thessalonica (1 Thess. v. 19), Ephesus (Eph. v. 18), and universally (Mark xvi. 17). From the epistles of Paul, who thanked God that he spake with tongues more than all or any of his Corinthian converts, we can gather a just idea of how he regarded this gift and of what it really was.

Firstly, then, it was a grace (*charisma*) of the spirit, yet not of the holy or pure spirit only, but of evil spirits also who on occasions had been known to take possession of the larynx of a saint and exclaim, "Jesus is Anathema." As no one could curse Jesus except under the influence of a devilish afflatus, so none could say "Jesus is Lord" except he was inspired by the Holy Spirit. But, secondly, the pneumatic utterances technically known as speaking with tongues failed to reach this level of intelligibility; for Paul compares "a tongue" to a material object which should merely make a noise, to a pipe or harp twanged or blown at random without tune or time, to a trumpet blaring idly and not according to a code of signal notes. Unless, therefore, he that has the gift of tongues also possess the gift of interpreting his exclamations, or unless some one present can do so for him, he had not better exercise it in church. He is a barbarian to others and they to him, since they cannot understand what is spoken by him. Paul discriminates between the Spirit which during these paroxysms both talks and prays to God and the *nous* or understanding which informs a believer's psalm, teaching, revelation or prophesy, and renders them intelligible, edifying and profitable to the assembly. Accordingly Paul lays down rules which he regarded as embodying the Lord's commandment. A man "that speaketh in a tongue speaketh not unto men, but unto God; for no man understandeth;" and therefore it is expedient that he keep this gift for his private chamber and there pour out the mysteries. In church it is best that he should confine himself to prophesying, for that brings to others "edification and comfort and consolation." If, however, tongues must be heard in the public assembly, then let not more than three of the saints exhibit the gift, and they only in succession. Nor let them exhibit it at all, unless there is some one present who can interpret the tongues and tell the meeting what it all means. If the whole congregation be talking with tongues all at once, and an unbeliever or one with no experience of pneumatic gifts come in, what will he think, asks Paul. Surely that "you are mad." So at Pentecost on the occasion of the first outpouring of the Spirit the saints were by the bystanders accused of being drunk (Acts ii. 15). In the church meeting, says Paul, "I had rather speak five words with my understanding, that I might instruct others also, than ten thousand words in a tongue."

The writer of Acts ii., anxious to prove that Providence from the first included the Gentiles in the Messianic Kingdom, assumes that the gift of tongues was a miraculous faculty of talking strange languages without having previously learned them. Augustine accordingly held that each of the disciples talked all languages miraculously; Chrysostom that each talked one other than his own. The Pentecostal inspiration has been construed as a providential antithesis to the confusion of tongues—an idea which Grotius expressed in the words: "Poena linguarum dispersit homines; donum linguarum dispersos in unum populum collegit." Competent critics to-day recognize that such a view is impossible; and it has been suggested with much probability that in the second chapter of Acts the words in *v.* 5: "Now there were dwelling . . . under heaven" as well as *vv.* 6–11: "because that every man . . . mighty works of God" were interpolated by Luke in the document he transcribed.[1] The faithful talking with tongues were taken by bystanders for drunken men, but intoxicated men do not talk in languages of which they are normally ignorant.[2]

Paul on the whole discouraged glossolaly. "Desire earnestly the greater gifts," he wrote to the Corinthians. The gift of tongues was suitable rather to children in the faith than to the mature. Tongues were, he felt, to cease whenever the perfect should come; and the believer who spoke with the tongues of men and of angels, if he had not love, was no better than the sounding brass and clanging cymbal of the noisy heathen mysteries. It was clearly a gift productive of much disturbance in the Church (1 Cor. xiv. 23). He would not, however, entirely forbid and quench it (1 Thess. v. 19), so long as decency and order were preserved.

It is not then surprising that we hear little of it after the apostolic age. It faded away in the great Church, and probably Celsus was describing Montanist circles (though Origen assumed that they were ordinary believers) when he wrote[3] of the many Christians of no repute who at the least provocation, whether within or without their temples, threw themselves about like inspired persons; while others did the same in cities or among armies in order to collect alms, roaming about cities or camps. They were wont to cry out, each of himself, "I am God; I am the Son of God; or I am the divine Spirit." They would indulge in prophecies of the last judgment, and back their threats with a string of strange, half-frantic and utterly unmeaning sounds, the sense of which no one with any intelligence could discover; for they were obscure gibberish, and merely furnished any fool or impostor with an occasion to twist the utterances as he chose to his own purposes.

In the above we get a glimpse both of the glossalist and of his interpreter as they appeared to the outside world; and the impression made on them is not unlike that which Paul apprehended would be left on outsiders by an indiscriminate use of the gift. Tertullian early in the 3rd century testifies that glossolaly still went on in the Montanist Church which he had joined; for we must so interpret the following passage in his *De anima*, cap. ix.: "There is among us at the present time a sister who is endowed with the charismatic gift of revelations, which she suffers through ecstasy in the spirit during the Sunday service in church. She converses with angels, sometimes even with the Lord, and both hears and see mysteries." The magical papyri teem with strings of senseless and barbaric words which probably answer to what certain of the Fathers called the language of demons. It has been suggested that we here have recorded the utterances of glossolalists.

The attitude of Paul toward glossolaly among his converts strikingly resembles Plato's opinion as expressed in the *Timaeus*, p. 72, of the enthusiastic ecstasies of the ancient μάντις (soothsayer). "God," he writes, "has given the art of divination not to the wisdom, but to the foolishness of man; for no man, when in his wits, attains prophetic truth and inspiration; but when he receives the inspired word either his intelligence is enthralled by sleep, or he is demented by some distemper or possession. And he who would understand what he remembers to have been said, whether in a dream or when he was awake, by the prophetic and enthusiastic nature, or what he has seen, must first recover his wits; and then he will be able to explain rationally what all

[1] This misunderstanding of Acts ii. has influenced the official Roman doctrine of demoniacal possession. The *Sacerdotale* indicates as one of the symptoms of possession the ability of the possessed to talk other tongues than his own. Cf. the *Fustis daemonum*, cap. xi. Venetus (1606): "*Aliqui sermonem alienum a patria sua loquuntur etsi nunquam e laribus paternis recesserint.*"

[2] It is noteworthy that in Eph. v. 18 Paul contrasts the being filled with the Spirit with the foolishness of intoxication with wine, and remarks that those filled with the Spirit speak to themselves in psalms and hymns and spiritual songs and give thanks always for all things.

[3] Origen, *Contra Celsum*, vii. 9.

such words and apparitions mean, and what indications they afford to this man or that, of past, present or future good and evil. But, while he continues demented, he cannot judge of the visions which he sees or the words which he utters. . . . And for this reason it is customary to appoint diviners or interpreters to be judges of the true inspiration."[1] From such passages as the above we infer that the gift of tongues and of their interpretation was not peculiar to the Christian Church, but was a repetition in it of a phase common in ancient religions. The very phrase γλώσσαις λαλεῖν, "to speak with tongues," was not invented by the New Testament writers, but borrowed from ordinary speech.

Virgil (*Aen.* vi. 46, 98) draws a life-like picture of the ancient prophetess "speaking with tongues." He depicts her quick changes of colour, her dishevelled hair, her panting breast, her apparent increase of stature as the god draws nigh and fills her with his divine afflatus. Then her voice loses its mortal's ring: "nec mortale sonans." The same morbid and abnormal trance utterances recur in Christian revivals in every age, *e.g.* among the mendicant friars of the 13th century, among the Jansenists, the early Quakers, the converts of Wesley and Whitefield, the persecuted protestants of the Cevennes, the Irvingites.

Oracular possession of the kind above described is also common among savages and people of lower culture; and Dr Tylor, in his *Primitive Culture*, ii. 14, gives examples of ecstatic utterance interpreted by the sane. Thus in the Sandwich Islands the god Oro gave his oracles through a priest who "ceased to act or speak as a voluntary agent, but with his limbs convulsed, his features distorted and terrific, his eyes wild and strained, he would roll on the ground foaming at the mouth, and reveal the will of the god in shrill cries and sounds violent and indistinct, which the attending priests duly interpreted to the people."

See E. B. Tylor, *Primitive Culture*; H. Weinel, *Die Wirkungen des Geistes und der Geister* (Freiburg, 1899); Shaftesbury's *Letter on Enthusiasm*; Mrs Oliphant, *Life of Irving*, vol. ii. (F. C. C.)

TONK, a native state of India, in the Rajputana agency. It consists of six isolated tracts, some of which are under the Central India agency. Total area, 2553 sq. m.; total population (1901), 273,201; estimated revenue £77,000. No tribute is payable. The chief, whose title is nawab, is a Mahommedan of Afghan descent. The founder of the family was Amir Khan, the notorious Pindari leader at the beginning of the 19th century, who received the present territory on submitting to the British in 1817. The nawab Mahommed Ibrahim Ali Khan, G.C.I.E., succeeded in 1867, and was one of the few chiefs who attended both Lord Lytton's Durbar in 1877 and the Delhi Durbar of 1903 as rulers of their states. The late minister, Sir Sahibzada Obeidullah Khan, was deputed on political duty to Peshawar during the Tirah campaign of 1897. Grain, cotton, opium and hides are the chief exports. Two of the outlying tracts of the state are served by two railways. Distress was caused by drought in 1899–1900. The town of Tonk is situated 1462 ft. above sea-level, 60 m. by road south from Jaipur, near the right bank of the river Banas. Pop. (1901), 38,759. It is surrounded by a wall, with a mud fort. It has a high school, the Walter female hospital under a lady superintendent, and a hospital for males.

There is another town in India called Tonk, or Tank, in Dera Ismail Khan district, North-West Frontier Province; pop. (1901), 4402. It is the residence of a nawab, who formerly exercised semi-independent powers. Here Sir Henry Durand, lieutenant-governor of the Punjab, was killed in 1870 when passing on an elephant under a gateway.

TONNAGE. The mode of ascertaining the tonnage of merchant ships is settled by the Merchant Shipping Acts. But before explaining the method by which this is computed, it is well to remark that there are several tonnages employed in different connexions. *Displacement tonnage* is that which is invariably used in respect of warships, and is the actual weight of water displaced by the vessel whose tonnage is being dealt with. Men-of-War are designed to carry all their weights, including coal, guns, ammunition, stores and water in tanks and in boilers, at a certain draught, and the tonnage attributed to them is the weight of water which at that designed draught they actually displace. This displacement tonnage is therefore a total made up of the actual weight of the ship's fabric and that of everything that is on board of her. It can be found by ascertaining the exact cubic space occupied by the part of her body which is immersed (including her rudder, propellers and external shafting) at the draught under consideration in cubic feet, and dividing this by 35, since 35 cubic feet of sea-water weigh one ton. Of course there is nothing to prevent displacement tonnage from being used in describing the size of merchant ships, and indeed in regard to the performances of fast steamships on trial it is usual to give their draught on the occasion when they are tested, and to state what was their actual displacement under these trial conditions. But it is obvious, from what has been said as to the components which go to make up the displacement at load draught, that this tonnage must, in respect of any individual ship, be the greatest figure which can be quoted in regard to her size. It is usual for dues to be assessed against merchant vessels in respect of their *registered tonnage.* This must therefore be fixed by authority, and at present vessels are measured by the officer of customs according to the rules laid down in the second schedule to the Merchant Shipping Act 1894. As will be seen from the explanation of the method adopted, this is a somewhat arbitrary process, and even the gross registered tonnage affords little indication of the actual size of the ship, whilst the under-deck and net tonnages are still less in accord with the extreme dimensions.

As to *length for tonnage*, the measurements start with the tonnage deck, which in vessels with less than three decks is the upper, and in vessels of three or more decks is the second from below. The length for tonnage is measured in a straight line along this deck from the inside of the inner plank at the bow to the inside of the inner plank at the stern, making allowance for the rake, if any, which the midship bow and stern timbers may have in the actual deck. When this is measured it is apparent into which of five classes the ship's tonnage-length places her. If she be under 50 ft. in length she falls into the first class, while if she be over 225 ft. in length she falls into the fifth class, the remaining three classes being intermediate to these. Vessels of the first class are measured as in four equal sections, and vessels of the larger class as in twelve equal sections, according to their length. Then at each of the points of division so marked off *transverse areas* are taken. This is done by measuring the depth in feet from a point at a distance of one-third of the round of the beam below the tonnage deck to the upper side of the floor timbers. Where the vessel has a ceiling and no water-ballast tanks at the point of measurement, 2½ in. is allowed for ceiling. But where there are such tanks the measurement is taken from the top of the tank and no allowance is made for ceiling, whether there in fact be any or not. If the midship depth so found exceeds 16 ft., each depth is divided into six equal parts, and the horizontal breadths are measured at each point of division and also at the upper and lower points of the depth, extending each measurement to the average thickness of that part of the ceiling which is between the points of measurement. They are then numbered from above, and the second, fourth and sixth multiplied by four, whilst the third and fifth are multiplied by two. The products are then added together. To the sum are added the first and the seventh breadths. This total having been multiplied by one-third the common interval between the breadths, the resultant is the transverse area. The transverse areas so obtained at each point of the vessel's length are numbered from the bow aft. Omitting the first and last, the second and every even area so obtained are multiplied by four, whilst the third and every odd area are multiplied by two. These products are added together, as are also those of the first and last areas if they yield anything, and the figure thus reached is multiplied by one-third of the common interval between the areas. This product is reckoned as the *cubical capacity of the*

[1] Jowett's translation.

ship in feet. When divided by 100 the result is the *registered under-deck tonnage* of the ship—subject to the additions and deductions ordered by the act. Directions of a kind similar to those already set out are given whereby the tonnage in the space enclosed between the tonnage and upper decks may be ascertained, and also for the measuring of any break, poop or other permanent closed-in space on the upper deck available for stores, and the sum of the capacity of these must be added to the under-deck tonnage to arrive at the *gross registered tonnage*. But an express proviso is enacted that no addition shall be made in respect of any building erected for the shelter of deck passengers and approved by the board of trade. In the process of arriving at the *net tonnage* the main deduction allowed from the gross tonnage is that of machinery space in steamships. The method of measurement here is similar to that by which the under-deck tonnage is reached. Where the engines and boilers are fitted in separate compartments, each compartment is measured separately, as is the screw shaft tunnel in the case of steamships propelled by screws. The tonnage of these spaces is reckoned, not from the tonnage deck, but from the crown of the space; whilst, if it has previously been reckoned in the gross tonnage, there may be an allowance for the space above the crown, if enclosed for the machinery or for the admission of light and air. Allowances are only made in respect of any machinery space if it be devoted solely to machinery or to light and air. It must not be used for cargo purposes or for cabins. Further, by the act itself in the case of paddle steamships, where the machinery space is above 20% and under 30% of the gross tonnage, it is allowed to be reckoned as 37% of such gross tonnage; whilst similarly, in the case of screw steamships, where such machinery space is over 13% and under 20% of the gross tonnage, it is allowed to be reckoned as 32%. Further deductions are also made in respect of space used solely for the accommodation of the master and the crew, and for the chart-room and signal-room, as well as for the wheel-house and chain cable locker and for the donkey-engine and boiler, if connected with the main pumps of the ship, and in sailing vessels for the sail locker. The space in the double bottom and in the water-ballast tanks, if these be not available for the carriage of fuel stores or cargo, is also deducted if it has been reckoned in the gross tonnage in the first instance.

From the rules above laid down it follows that it is possible for vessels, if built with a full midship section, to have a gross registered tonnage considerably below what the actual cubical capacity of the ship would give, whilst in the case of steam tugs of high power it is not unprecedented, owing to the large allowances for machinery and crew spaces, for a vessel to have a registered net tonnage of nil.

Suez Canal dues being charged on what is practically the registered tonnage (though all deductions permitted by the British board of trade are not accepted), it is usual, at all events in the British navy, for warships to be measured for what would be their registered tonnage if they were merchant ships, so that in case they may wish to pass through the canal a scale of payment may be easily reached. But such tonnage is never spoken of in considering their size relative to other vessels.

Two other tonnages are also made use of in connexion with merchant ships, especially when specifications for vessels are being made. The first of these is *measurement capacity*. This is found by measuring out the true cubic capacity of the holds, whereby it is found what amount of light measurement goods can be carried. The second is *deadweight capacity*. This is generally given as excluding what is carried in the coal bunkers, and it is therefore the amount of deadweight which can be carried in the holds at load draught when the vessel is fully charged with coals and stores. (B. W. G.)

TONNAGE AND POUNDAGE, in England, customs duties anciently imposed upon exports and imports, the former being a duty upon all wines imported in addition to prisage and butlerage, the latter a duty imposed *ad valorem* at the rate of twelvepence in the pound on all merchandise imported or exported. The duties were levied at first by agreement with merchants (poundage in 1302, tonnage in 1347), then granted by parliament in 1373, at first for a limited period only. They were considered to be imposed for the defence of the realm. From the reign of Henry VI. until that of James I. they were usually granted for life. They were not granted to Charles I., and in 1628 that king took the unconstitutional course of levying them on his own authority, a course denounced a few years later by 16 Car. I. c. 18 (1640), when the Long Parliament granted them for two months. After the Restoration they were granted to Charles II. and his two successors for life. By acts of Anne and George I. the duties were made perpetual, and mortgaged for the public debt. In 1787 they were finally abolished, and other modes of obtaining revenue substituted, by 27 Geo. III. c. 13 (1787).

Poundage also signifies a fee paid to an officer of a court for his services, *e.g.* to a sheriff's officer, who is entitled by 29 Eliz. c. 4 (1586–1587) to a poundage of a shilling in the pound on an execution up to £100, and sixpence in the pound above that sum.

TONNERRE, a town of north-central France, capital of an arrondissement in the department of Yonne, 52 m. S.E. of Sens on the Paris-Lyon railway. Pop. (1906), 3974. It is situated on a slope of the vineclad hills on the left bank of the Armançon. At the foot of the hill rises the spring of Fosse-Dionne, enclosed in a circular basin 49 ft. in diameter. The town has two interesting churches. That of St Pierre, which crowns the hill, possesses a fine lateral portal of the Renaissance period to which the church, with the exception of the choir (1351), belongs. The church of Notre-Dame is mainly Gothic, but the façade is a fine specimen of Renaissance architecture. The Salle des Malades, a large timber-roofed apartment in the hospital, dates from the end of the 13th century and is used as a chapel. It is 330 ft. long and contains the tombs of Margaret of Burgundy, wife of Charles of Anjou, king of Sicily, and foundress of the hospital, and of François-Michel Le Tellier, marquis of Louvois, war minister of Louis XIV. The hospital itself was rebuilt in the 19th century. The Renaissance Hôtel d'Uzès was built in the 16th century. Tonnerre is the seat of a sub-prefect and has a tribunal of first instance. The vineyards of the vicinity produce well-known wines. The trade of the town is chiefly in wine, in the good building-stone found in the neighbourhood and in Portland cement. Cooperage is carried on.

Its ancient name of *Tornodorum* points to a Gallic or Gallo-Roman origin for Tonnerre. In the 6th century it became the capital of the region of Tonnerrois and in the 10th century of a countship. After passing into the possession of several noble families, it was bought from a count of Clermont-Tonnerre by Louvois, by whose descendants it was held up to the time of the Revolution.

TONQUA BEAN. The Tonqua, Tonka or Tonquin bean, also called the coumara nut, is the seed of *Dipterix odorata*, a leguminous tree growing to a height of 80 ft., native of tropical South America. The drupe-like pod contains a single seed possessed of a fine sweet "new-mown hay" odour, due to the presence of coumarin (*q.v.*). Tonqua beans are used principally for scenting snuff and as an ingredient in perfume sachets and in perfumers' "bouquets."

TÖNSBERG, a fortified seaport of Norway, in Jarlsberg-Laurvik *amt* (county), situated on a bay on the south coast, near the entrance to Christiania Fjord, 72 m. S. by W. of Christiania on the Skien railway. Pop. (1900), 8620. It is one of the most ancient towns in Norway. It is the headquarters of a sealing and whaling fleet. The principal industries are refineries for preparing whale and seal oil and saw-mills. An interesting collection of antiquities and whaling implements is preserved in the Slotstaarn on Castle Hill.

TONSILLITIS, acute inflammation of the tonsils, or quinsy, due to the invasion of the tonsil, or tonsils, by septic micro-organisms which may have gained access through the mouth or by the blood-stream. Sometimes the attack comes on as the result of direct exposure to sewer gas, and it is not at all an uncommon affection of house surgeons, nurses and others who have to spend most of their time in a hospital. The association of quinsy with rheumatism may be the result of the infection of the tonsils by the micro-organisms or the toxins of that disease. Acute tonsillitis is very apt to run on to the formation of abscess. Quinsy may begin with a feeling of chilliness or with an attack of shivering. Then comes on a swelling in the throat with pain, tenderness and difficulty in swallowing. Indeed, if both tonsils are acutely inflamed it may be impossible to swallow even fluid and the breathing may be seriously embarrassed. The temperature may be raised several degrees. There is pain about the ear and about the jaw, and there is a swelling of the glands in the neck. The breath is offensive and the tongue is thickly coated. There may be some yellowish markings on the surface of the tonsil, but these differ from the patches of "false membrane" of diphtheria in that they can be easily brushed off by a swab, but often a true diagnosis can only be made by bacteriological examination. The treatment consists in giving a purgative, and in encouraging the patient to use an inhaler containing hot carbolized water. Hot compresses also may be applied to the neck. As regards medicines, the most trustworthy are salicylic acid, iron and quinine. As soon as abscess threatens, a slender-bladed knife should be thrust from before backward deeply into the swollen mass. And if, as most likely happens, matter then escapes, the patient's distress speedily ends. Convalescence having set in, a change of air and course of tonic treatment will be advisable.

Chronic tonsillitis is often associated with adenoid vegetations at the back of the throat of tuberculous or delicate children, such children being spoken of as being "liable to sore throat." Chronic enlargement of the tonsils may seriously interfere with a child's general health and vigour and, should the condition not subside under general measures such as a stay at a bracing seaside place and the taking of cod-liver oil and iron, it will be well to treat the tonsils by operation. (E. O.*)

TONSON, the name of a family of London booksellers and publishers. Richard and Jacob Tonson (*c.* 1656–1736), sons of a London barber-surgeon, started in 1676 and 1677 independently as booksellers and publishers in London. In 1679 Jacob, the better known of the two, bought and published Dryden's *Troilus and Cressida*, and from that time was closely associated with Dryden, and published most of his works. He published the *Miscellany Poems* (1684–1708) under Dryden's editorship, the collection being known indifferently as *Dryden's* or *Tonson's Miscellany*, and also Dryden's translation of Virgil (1697). Serious disagreements over the price paid, however, arose between poet and publisher, and in his *Faction Displayed* (1705) Dryden described Tonson as having "two left legs, and Judas-coloured hair." Subsequently the relations between the two men improved. The brothers jointly published Dryden's *Spanish Friar* (1683). Jacob Tonson also published Congreve's *Double Dealer*, Sir John Vanbrugh's *The Faithful Friend* and *The Confederacy*, and the pastorals of Pope, thus justifying Wycherly's description of him as "gentleman usher to the Muses." He bought also the valuable rights of *Paradise Lost*, half in 1683 and half in 1690. This was his first profitable venture in poetry. In 1712 he became joint publisher with Samuel Buckley of the *Spectator*, and in the following year published Addison's *Cato*. He was the original secretary and a prominent member of the Kit-Cat Club. About 1720 he gave up business and retired to Herefordshire, where he died on the 2nd of April 1736. His business was carried on by his nephew, Jacob Tonson, jun. (d. 1735), and subsequently by his grand-nephew, also Jacob (d. 1767).

TONSURE (Lat. *tonsura*, from *tondere*, to shave), a religious observance in the Roman Catholic and Orthodox Eastern Churches, consisting of the shaving or cutting part of the hair of the head as a sign of dedication to special service. The reception of the tonsure in these churches is the initial ceremony which marks admission to orders and to the rights and privileges of clerical standing. It is administered by the bishop with an appropriate ritual. Candidates for the rite must have been confirmed, be adequately instructed in the elements of the Christian faith, and be able to read and write. Those who have received it are bound (unless in exceptional circumstances) to renew the mark, consisting of a bare circle on the crown of the head, at least once a month, otherwise they forfeit the privileges it carries. The practice is not a primitive one; Tertullian simply advises Christians to avoid vanity in dressing their hair, and Jerome deprecates both long and closely cropped hair. According to Prudentius (Περιστ. xiii. 30) it was customary for the hair to be cut short at ordination. Paulinus of Nola (*c.* 490) alludes to the tonsure as in use among the (Western) monks; from them the practice quickly spread to the clergy. For Gaul about the year 500 we have the testimony of Sidonius Apollinaris (iv. 13), who says that Germanicus the bishop had his hair cut "in rotae speciem."

The earliest instance of an ecclesiastical precept on the subject occurs in can. 41 of the Council of Toledo (A.D. 633): "omnes clerici, detonso superius capite toto, inferius solam circuli coronam relinquant." Can. 33 of the Quinisext council (692) requires even singers and readers to be tonsured. Since the 8th century three tonsures have been more or less in use, known respectively as the Roman, the Greek and the Celtic. The first two are sometimes distinguished as the tonsure of Peter and the tonsure of Paul. The Roman or St Peter's tonsure prevailed in France, Spain and Italy. It consisted in shaving the whole head, leaving only a fringe of hair supposed to symbolize the crown of thorns. Late in the middle ages this tonsure was lessened for the clergy, but retained for monks and friars. In the Eastern or St Paul's tonsure the whole head was shaven, but when now practised in the Eastern Church this tonsure is held to be adequately shown when the hair is shorn close. In the Celtic tonsure (tonsure of St John, or, in contempt, tonsure of Simon Magus) all the hair in front of a line drawn over the top of the head from ear to ear was shaven (a fashion common among the Hindus). The question of the Roman or Celtic tonsure was one of the points in dispute in the early British Church, settled in favour of the Roman fashion at the Council of Whitby (664). The tonsure at first was never given separately, and even children when so dedicated were appointed readers, as no one could belong to the clerical state without at least a minor order. From the 7th century, however, children were tonsured without ordination, and later on adults anxious to escape secular jurisdiction were often tonsured without ordination. Till the 10th century the tonsure could be given by priests or even by laymen, but its bestowal was gradually restricted to bishops and abbots.

TONTINE, a system of life insurance owing its name to Lorenzo Tonti, an Italian banker, born at Naples early in the 17th century, who settled in France about 1650. In 1653 he proposed to Cardinal Mazarin a new scheme for promoting a public loan. A total of 1,025,000 livres was to be subscribed in ten portions of 102,500 livres each by ten classes of subscribers, the first class consisting of persons under 7, the second of persons above 7 and under 14, and so on to the tenth, which consisted of persons between 63 and 70. The annual fund of each class was to be divided among the survivors of that class, and on the death of the last individual the capital was to fall to the state. This plan of operations was authorized under the name of "tontine royale" by a royal edict, but this the parlement refused to register, and the idea remained in abeyance till 1689, when it was revived by Louis XIV., who established a tontine of 1,400,000 livres divided into fourteen classes of 100,000 each, the subscription being 300 livres. This tontine was carried on till 1726, when the last beneficiary died—a widow who at the time of her decease was drawing an annual income of 73,500 livres. Several other government tontines were afterwards set on foot; but in 1763 restrictions were introduced, and in 1770 all tontines at the time in existence were wound up. Private tontines continued to flourish in France for some years, the "tontine Lafarge," the most celebrated of the kind, being opened in 1791 and closed in 1889.

The tontine principle has often been applied in Great Britain, at one time in connexion with government life annuities. Many such tontines were set on foot between the years 1773 and 1789, those of 1773, 1775 and 1777 being commonly called the Irish tontines, as the money was borrowed under acts of the Irish parliament. The most important English tontine was that of 1789, which was created by 29 Geo. III. c. 41. Under this act over a million was raised in 10,000 shares of £100, 5s. It was also often applied to the purchase of estates or the erection of buildings. The investor staked his money on the chance of his own life or the life of his nominee enduring for a longer period than the other lives involved in the speculation, in which case he expected to win a large prize. It was occasionally introduced into life assurance, more particularly by American life offices, but newer and more ingenious forms of contract have now made the tontine principle practically a thing of the past. (See NATIONAL DEBT; INSURANCE.)

TOOKE, JOHN HORNE (1736–1812), English politician and philologist, third son of John Horne, a poulterer in Newport Market, whose business the boy when at Eton happily veiled under the title of a "Turkey merchant," was born in Newport Street, Long Acre, Westminster, on the 25th of June 1736. After passing some time at school in Soho Square, and at a Kentish village, he went from 1744 to 1746 to Westminster School and for the next five or six years was at Eton. On the 12th of January 1754 he was admitted as sizar at St John's College, Cambridge, and took his degree of B.A. in 1758, as last but one of the *senior optimes*, Richard Beadon, his lifelong friend, afterwards bishop of Bath and Wells, being a wrangler in the same year. Horne had been admitted on the 9th of November 1756, as student at the Inner Temple, making the friendship of John Dunning and Lloyd Kenyon, but his father wished him to take orders in the English Church, and he was ordained deacon on the 23rd of September 1759 and priest on the 23rd of November 1760. For a few months he was usher at a boarding school at Blackheath, but on the 26th of September 1760 he became perpetual curate of New Brentford, the incumbency of which his father had purchased for him, and he retained its scanty profits until 1773. During a part of this time (1763–1764) he was absent on a tour in France, acting as the bear-leader of a son of the miser Elwes. Under the excitement created by the actions of Wilkes, Horne plunged into politics, and in 1765 brought out a scathing pamphlet on Lords Bute and Mansfield, entitled "The Petition of an Englishman." In the autumn of 1765 he escorted to Italy the son of a Mr Taylor. In Paris he made the acquaintance of Wilkes, and from Montpellier, in January 1766, addressed a letter to him which sowed the seeds of their personal antipathy. In the summer of 1767 Horne landed again on English soil, and in 1768 secured the return of Wilkes to parliament for Middlesex. With inexhaustible energy he promoted the legal proceedings over the riot in St George's Fields, when a youth named Allen was killed, and exposed the irregularity in the judge's order for the execution of two Spitalfields weavers. His dispute with George Onslow, member for Surrey, who at first supported and then threw over Wilkes for place, culminated in a civil action, ultimately decided, after the reversal of a verdict which had been obtained through the charge of Lord Mansfield, in Horne's favour, and in the loss by his opponent of his seat in parliament. An influential association, called "The Society for Supporting the Bill of Rights," was founded, mainly through the exertions of Horne, in 1769, but the members were soon divided into two opposite camps, and in 1771 Horne and Wilkes, their respective leaders, broke out into open warfare, to the damage of their cause. On the 1st of July 1771 Horne obtained at Cambridge, though not without some opposition from members of both the political parties, his degree of M.A. Earlier in that year he claimed for the public the right of printing an account of the debates in parliament, and after a protracted struggle between the ministerial majority and the civic authorities, the right was definitely established. The energies of the indefatigable parson knew no bounds. In the same year (1771) he crossed swords with Junius, and ended in disarming his masked antagonist. Up to this time Horne's fixed income consisted of those scanty emoluments attached to a position which galled him daily. He resigned his benefice in 1773 and betook himself to the study of the law and philology. An accidental circumstance, however, occurred at this moment which largely affected his future. His friend Mr William Tooke had purchased a considerable estate, including Purley Lodge, south of the town of Croydon in Surrey. The possession of this property brought about frequent disputes with an adjoining landowner, Thomas de Grey, and, after many actions in the courts, his friends endeavoured to obtain, by a bill forced through the houses of parliament, the privileges which the law had not assigned to him (February 1774). Horne, thereupon, by a bold libel on the Speaker, drew public attention to the case, and though he himself was placed for a time in the custody of the serjeant-at-arms, the clauses which were injurious to the interest of Mr Tooke were eliminated from the bill. Mr Tooke declared his intention of making Horne the heir of his fortune, and, if the design was never carried into effect, during his lifetime he bestowed upon him large gifts of money. No sooner had this matter been happily settled than Horne found himself involved in serious trouble. For his conduct in signing the advertisement soliciting subscriptions for the relief of the relatives of the Americans "murdered by the king's troops at Lexington and Concord," he was tried at the Guildhall on the 4th of July 1777, before Lord Mansfield, found guilty, and committed to the King's Bench prison in St George's Fields, from which he only emerged after a year's durance, and after a loss in fines and costs amounting to £1200. Soon after his deliverance he applied to be called to the bar, but his application was negatived on the ground that his orders in the Church were indelible. Horne thereupon tried his fortune, but without success, on farming some land in Huntingdonshire. Two tracts about this time exercised great influence in the country. One of them, *Facts Addressed to Landholders*, &c. (1780), written by Horne in conjunction with others, criticizing the measures of Lord North's ministry, passed through numerous editions; the other, *A Letter on Parliamentary Reform* (1782), addressed by him to Dunning, set out a scheme of reform, which he afterwards withdrew in favour of that advocated by Pitt. On his return from Huntingdonshire he became once more a frequent guest at Mr Tooke's house at Purley, and in 1782 assumed the name of Horne Tooke. In 1786 Horne Tooke conferred perpetual fame upon his benefactor's country house by adopting, as a second title of his elaborate philological treatise of Ἔπεα πτερόεντα, the more popular though misleading title of *The Diversions of Purley*. The treatise at once attracted attention in England and the Continent. The first part was published in 1786, the second in 1805. The best edition is that which was published in 1829, under the editorship of Richard Taylor, with the additions written in the author's interleaved copy.

Between 1782 and 1790 Tooke gave his support to Pitt, and in the election for Westminster, in 1784, threw all his energies into opposition to Fox. With Fox he was never on terms of friendship, and Samuel Rogers, in his *Table Talk*, asserts that their antipathy was so pronounced that at a dinner party given by a prominent Whig not the slightest notice was taken by Fox of the presence of Horne Tooke. It was after the election of Westminster in 1788 that Tooke depicted the rival statesmen (Lord Chatham and Lord Holland, William Pitt and C. J. Fox) in his celebrated pamphlet of *Two Pair of Portraits*. At the general election of 1790 he came forward as a candidate for that distinguished constituency, in opposition to Fox and Lord Hood, but was defeated; and, at a second trial in 1796, he was again at the bottom of the poll. Meantime the excesses of the French republicans had provoked reaction in England, and the Tory ministry adopted a policy of repression. Horne Tooke was arrested early on the morning of the 16th of May 1794, and conveyed to the Tower. His trial for high treason lasted for six days (17th to 22nd of November) and ended in his acquittal, the jury only taking eight minutes to settle their verdict. His public life after this event was only distinguished by one act of importance. Through the influence of the second Lord Camelford, the fighting peer, he was returned to parliament in 1801 for the pocket borough of Old Sarum. Lord Temple endeavoured to secure his exclusion on the ground that he had taken orders in the Church, and one of Gilray's caricatures delineates the two politicians, Temple and Camelford, playing at battledore and shuttlecock, with Horne Tooke as the shuttlecock. The ministry of Addington would not support this suggestion, but a bill was at once introduced by them and carried into law, which rendered all persons in holy orders ineligible to sit in the House of Commons, and Horne Tooke sat for that parliament only.

The last years of Tooke's life were spent in retirement in a house on the west side of Wimbledon Common. The traditions of his Sunday parties have lasted unimpaired to this day, and the most pleasant pages penned by his biographer describe the politicians and the men of letters who gathered round his hospitable board. His conversational powers rivalled those of Dr Johnson; and, if more of his sayings have not been chronicled for the benefit of posterity, the defect is due to the absence of a Boswell. Through the liberality of his friends, his last days were freed from the pressure of poverty, and he was enabled to place his illegitimate son in a position which soon brought him wealth, and to leave a competency to his two illegitimate daughters. Illness seized him early in 1810, and for the next two years his sufferings were acute. He died in his house at Wimbledon on the 18th of March 1812, and his body was buried with that of his mother at Ealing, the tomb which he had prepared in the garden attached to his house at Wimbledon being found unsuitable for the interment. An altar-tomb still stands to his memory in Ealing churchyard. A catalogue of his library was printed in 1813.

The *Life of Horne Tooke*, by Alexander Stephens, is written in an unattractive style and was the work of an admirer only admitted to his acquaintance at the close of his days. The notice in the *Quarterly Review*, June 1812, of W. Hamilton Reid's compilation, is by J. W. Ward, Lord Dudley. The main facts of his life are set out by Mr J. E. Thorold Rogers, in his *Historical Gleanings*, 2nd series. Many of Horne Tooke's wittiest sayings are preserved in the *Table Talk* of Samuel Rogers and S. T. Coleridge. (W. P. C.)

TOOKE, THOMAS (1774–1858), English economist, was born at St Petersburg on the 29th of February 1774. Entering a large Russian house in London at an early age, he acquired sound practical experience of commercial matters and became a recognized authority on finance and banking. He was one of the earliest advocates of free trade and drew up the *Merchants' Petition* presented to the House of Commons by Alexander Baring, afterwards Lord Ashburton. He gave evidence before several parliamentary committees, notably the committee of 1821, on foreign trade, and those of 1832, 1840 and 1848 on the Bank Acts. He was elected a fellow of the Royal Society in 1821. He died in London on the 26th of February 1858.

Tooke was the author of *Thoughts and Details on the High and Low Prices of the last Thirty Years* (1823), *Considerations on the State of the Currency* (1826), in both of which he showed his hostility to the policy afterwards carried out in the Bank Act of 1844, but he is best known for his *History of Prices and of the State of the Circulation during the Years 1793–1856* (6 vols., 1838–1857). In the first four volumes he treats (*a*) of the prices of corn, and the circumstances affecting prices; (*b*) the prices of produce other than corn; and (*c*) the state of the circulation. The two final volumes, written in conjunction with W. Newmarch (*q.v.*), deal with railways, free trade, banking in Europe and the effects of new discoveries of gold.

TOOL (O. Eng. *tôl*, generally referred to a root seen in the Goth. *taujan*, to make, or in the English word "taw," to work or dress leather), an implement or appliance used by a worker in the treatment of the substances used in his handicraft, whether in the preliminary operations of setting out and measuring the materials, in reducing his work to the required form by cutting or otherwise, in gauging it and testing its accuracy, or in duly securing it while thus being treated.

For the tools of prehistoric man see such articles as ARCHAEOLOGY; FLINT IMPLEMENTS; and EGYPT, § *Art and Archaeology*.

In beginning a survey of tools it is necessary to draw the distinction between hand and machine tools. The former class includes any tool which is held and operated by the unaided hands, as a chisel, plane or saw. Attach one of these to some piece of operating mechanism, and it, with the environment of which it is the central essential object, becomes a machine tool. A very simple example is the common power-driven hack saw for metal, or the small high-speed drill, or the wood-boring auger held in a frame and turned by a winch handle and bevel-gears. The difference between these and a big frame-saw cutting down a dozen boards simultaneously, or the immense machine boring the cylinders of an ocean liner, or the great gun lathe, or the hydraulic press, is so vast that the relationship is hardly apparent. Often the tool itself is absolutely dwarfed by the machine, of which nevertheless it is the central object and around which the machine is designed and built. A milling machine weighing several tons will often be seen rotating a tool of but two or three dozen pounds' weight. Yet the machine is fitted with elaborate slides and self-acting movements, and provision for taking up wear, and is worth some hundreds of pounds sterling, while the tool may not be worth two pounds. Such apparent anomalies are in constant evidence. We propose, therefore, first to take a survey of the principles that underlie the forms of tools, and then pursue the subject of their embodiment in machine tools.

HAND TOOLS

The most casual observation reveals the fact that tools admit of certain broad classifications. It is apparent that by far the larger number owe their value to their capacity for cutting or removing portions of material by an incisive or wedge-like action, leaving a smooth surface behind. An analysis of the essential methods of operation gives a broad grouping as follows:—

I. The chisel group . .	Typified by the chisel of the woodworker.	
II. The shearing group .	,,	,, scissors.
III. The scrapers . . .	,,	,, cabinet-maker's scrape.
IV. The percussive and detrusive group .	,,	,, hammer and the punch.
V. The moulding group .	,,	,, trowel.

The first three are generally all regarded as cutting tools, notwithstanding that those in II. and III. do not operate as wedges, and therefore are not true chisels. But many occupy a border-line where the results obtained are practically those due to cutting, as in some of the shears, saws, milling cutters, files and grinding wheels, where, if the action is not directly wedge-like, it is certainly more or less incisive in character.

Cutting Tools.—The cutting edge of a tool is the practical outcome of several conditions. Keenness of edge, equivalent to a small degree of angle between the tool faces, would appear at first sight to be the prime element in cutting, as indeed it is in the case of a razor, or in that of a chisel for soft wood. But that is not the prime condition in a tool for cutting iron or steel. Strength is of far greater importance, and to it some keenness of edge must be sacrificed. All cutting tools are wedges; but a razor or a chisel edge, included between angles of 15° or 20°, would be turned over at once if presented to iron or steel, for which angles of from 60° to 75° are required. Further, much greater rigidity in the latter, to resist spring and fracture, is necessary than in the former, because the resistance to cutting is much greater. A workman can operate a turning tool by hand, even on heavy pieces of metal-work. Formerly all turning, no matter how large, was done by hand-operated tools, and after great muscular exertion a few pounds of metal might be removed in an hour. But coerce a similarly formed tool in a rigid guide or rest, and drive it by the power of ten or twenty men, and it becomes possible to remove say a hundredweight of chips in an hour. Or, increase the size of the tool and its capacity for endurance, and drive by the power of 40 or 60 horses, and half a ton of chips may be removed in an hour.

All machine tools of which the chisel is the type operate by cutting; that is, they act on the same principle and by the same essential method as the knife, razor or chisel, and not by that of the grindstone. A single tool, however, may act as a cutting instrument at one time and as a scrape at another. The butcher's knife will afford a familiar illustration. It is used as a cutting tool when severing a steak, but it becomes a scrape when used to clean the block. The difference is not therefore due to the form of the knife, but to the method of its application, a distinction which holds good in reference to the tools used by engineers. There is a very old hand tool once much used in the engineer's turnery, termed a "graver." This was employed for cutting and for scraping indiscriminately, simply by varying the angle of its presentation. At that time the question of the best cutting angles was seldom raised or discussed, because the manipulative instinct of the turner settled it as the work proceeded, and as the material operated on varied in texture and degree of hardness. But since the use of the slide rest holding tools rigidly fixed has become general, the question of the most suitable tool formation has been the subject of much experiment and discussion. The almost unconscious experimenting which goes on every day in every workshop in the world proves that there may be a difference of several degrees of angle in tools doing similar work, without having any appreciable effect upon results. So long as certain broad principles and reasonable limits are observed, that is sufficient for practical purposes.

Clearly, in order that a tool shall cut, it must possess an incisive form. In fig. 1, *A* might be thrust over the surface of the plate of metal, but no cutting action could take place. It would simply grind and polish the surface. If it were formed like *B*, the grinding action would give place to scraping, by which some material would be removed. Many tools are formed thus, but there is still no incisive or knife-like action, and the tool is simply a scrape and not a cutting tool. But *C* is a cutting tool, possessing penetrative capacity. If now *B* were tilted backwards as at *D*, it would at once become a cutting tool. But its bevelled face would rub and grind on the surface of the work, producing friction and heat, and interfering with the penetrative action of the cutting edge. On the other hand, if C were tilted forwards as at E its action would approximate to that of a scrape for the time being. But the high angle of the hinder bevelled face would not afford adequate support to the cutting edge, and the latter would therefore become worn off almost instantly, precisely as that of a razor or wood-working chisel would crumble away if operated on hard metal. It is obvious

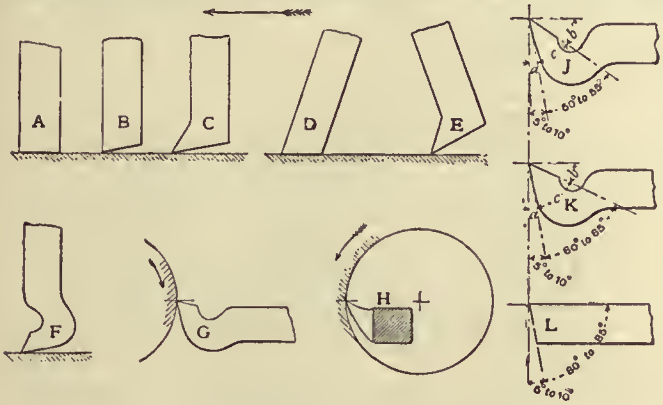


FIG. 1.

therefore that the correct form for a cutting tool must depend upon a due balance being maintained between the angle of the front and of the bottom faces—"front" or "top rake," and "bottom rake" or "clearance"—considered in regard to their *method of presentation* to the work. Since, too, all tools used in machines are held rigidly in one position, differing in this respect from hand-operated tools, it follows that a constant angle should be given to instruments which are used for operating on a given kind of metal or alloy. It does not matter whether a tool is driven in a lathe, or a planing machine, or a sharper or a slotter; whether it is cutting on external or internal surfaces, it is always maintained in a direction perpendicularly to the point of application as in fig. 1, *F*, *G*, *H*, planing, turning and boring respectively. It is consistent with reason and with fact that the softer and more fibrous the metal, the keener must be the formation of the tool, and that, conversely, the harder and more crystalline the metal the more obtuse must be the cutting angles, as in the extremes of the razor and the tools for cutting iron and steel already instanced. The three figures *J*, *K*, *L* show tools suitably formed for wrought iron and mild steel, for cast iron and cast steel, and for brass respectively. Cast iron and cast steel could not be cut properly with the first, nor wrought iron and fibrous steel with the second, nor either with the third. The angles given are those which accord best with general practice, but they are not constant, being varied by conditions, especially by lubrication and rigidity of fastenings. The profiles of the first and second tools are given mainly with the view of having material for grinding away, without the need for frequent reforging. But there are many tools which are formed quite differently when used in tool-holders and in turrets, though the same essential principles of angle are observed.

The *angle of clearance*, or *relief*, *a*, in fig. 1, is an important detail of a cutting tool. It is of greater importance than an exact angle of top rake. But, given some sufficient angle of clearance, its exact amount is not of much moment. Neither need it be uniform for a given cutting edge. It may vary from say 3° to 10°, or even 20°, and under good conditions little or no practical differences will result. Actually it need never vary much from 5° to 7°. The object in giving a clearance angle is simply to prevent friction between the non-cutting face immediately adjacent to the edge and the surface of the work. The limit to this clearance is that at which insufficient support is afforded to the cutting edge. These are the two facts, which if fulfilled permit of a considerable range in clearance angle. The softer the metal being cut the greater can be the clearance; the harder the material the less clearance is permissible because the edge requires greater *support*.

The *front*, or *top rake*, *b* in fig. 1, is the angle or slope of the front, or top face, of the tool; it is varied mainly according as materials are crystalline or fibrous. In the turnings and cuttings taken off the more crystalline metals and alloys, the broken appearance of the chips is distinguished from the shavings removed from the fibrous materials. This is a feature which always distinguishes cast iron and unannealed cast steel from mild steel, high carbon steel from that low in carbon, and cast iron from wrought iron. It indicates too that extra work is put on the tool in breaking up the chips, following immediately on their severance, and when the comminutions are very small they indicate insufficient top rake. This is a result that turners try to avoid when possible, or at least to minimize. Now the greater the slope of the top rake the more easily will the cuttings come away, with the minimum of break in the crystalline materials and absolutely unbroken over lengths of many feet in the fibrous ones. The breaking up, or the continuity of the cuttings, therefore affords an indication of the suitability of the amount of top rake to its work. But compromise often has to be made between the ideal and the actual. The amount of top rake has to be limited in the harder metals and alloys in order to secure a *strong tool angle*, without which tools would lack the endurance required to sustain them through several hours without regrinding.

The *tool angle*, *c*, is the angle included between top and bottom faces, and its amount, or thickness expressed in degrees, is a measure of the strength and endurance of any tool. At extremes it varies from about 15° to 85°. It is traceable in all kinds of tools, having very diverse forms. It is difficult to place some groups in the cutting category; they are on the border-line between cutting and scraping instruments.

Typical Tools.—A bare enumeration of the diverse forms in which tools of the chisel type occur is not even possible here. The grouped illustrations (figs. 2 to 6) show some of the types, but it will be understood that each is varied in dimensions, angles and outlines to suit all the varied kinds of metals and alloys and conditions of operation. For, as every tool has to be gripped in a holder of some kind, as a slide-rest, tool-box, turret, tool-holder, box, cross-slide, &c., this often determines the choice of some one form in preference to another. A broad division is that into roughing and finishing

traverse of the second. The following are some of the principal forms. The round-nosed roughing tool (fig. 2) *B* is of straightforward type, used for turning, planing and shaping. As the correct tool angle can only occur on the middle plane of the tool, it is usual to employ cranked tools, *C*, *D*, *E*, right- and left-handed, for heavy and moderately heavy duty, the direction of the cranking corresponding with that in which the tool is required to traverse. Tools for boring are cranked and many for planing (fig. 3). The slotting tools (fig. 4) embody the same principle, but their shanks are in line with the direction of cutting. Many roughing and finishing tools are of knife type *H*. Finishing tools have broad edges, *F*, *G*, *H*. They occur in straightforward and right- and left-hand types. These as a rule remove less than $\frac{1}{16}$ in. in depth, while the roughing tools may cut an inch or more into the metal. But the traverse of the first often exceeds an inch, while in that of the second $\frac{1}{8}$ in. is a very coarse amount of feed. Spring tools, *G*, used less now than formerly, are only of value for imparting a smooth finish to a surface. They are finishing tools only. Some spring tools are formed with considerable top rake, but generally they act by scraping only.

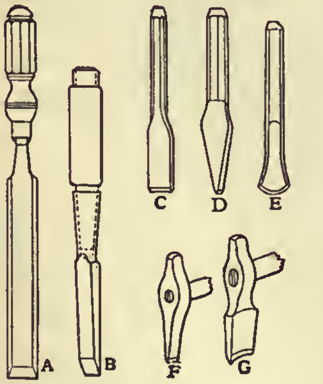

FIG. 6.—Group of Chisels.

A, Paring chisel.
B, Socket chisel for heavy duty.
C, Common chipping chisel.
D, Narrow cross-cut or cape chisel.
E, Cow-mouth chisel, or gouge.
F, Straight chisel or sett.
G, Hollow chisel or sett.

Solid Tools v. *Tool-holders.*—It will be observed that the foregoing are solid tools; that is, the cutting portion is forged from a solid bar of steel. This is costly when the best tool steel is used, hence large numbers of tools comprise *points* only, which are gripped in permanent holders in which they interchange. Tool steel usually ranges from about $\frac{1}{2}$ in. to 4 in. square; most engineers' work is done with bars of from $\frac{1}{2}$ in. to $1\frac{1}{2}$ in. square. It is in the smaller and medium sizes of tools that holders prove of most value. Solid tools, varying from $2\frac{1}{2}$ in. to 4 in. square, are used for the heaviest cutting done in the planing machine. Tool-holders are not employed for very heavy work, because the heat generated would not get away fast enough from small tool points. There are scores of holders; perhaps a dozen good approved types are in common use. They are divisible into three great groups: those in which the top rake of the tool point is embodied in the holder, and is constant; those in which the clearance is similarly embodied; and those in which neither is provided for, but in which the tool point is ground to any angle. Charles Babbage designed the first tool-holder, and the essential type survives in several modern forms. The best-known holders now are the Tangye, the Smith & Coventry, the Armstrong, some by Mr C. Taylor, and the Bent. The Smith & Coventry (fig. 5), used more perhaps than any other single design, includes two forms. In one *E* the tool is a bit of round steel set at an angle which gives front rake, and having the top end ground to an angle of top rake. In the other *A* the tool has the section of a truncated wedge, set for constant top rake, or cutting angle, and having bottom rake or clearance angle ground. The Smith & Coventry round tool is not applicable for all classes of work. It will turn plain work, and plane level faces, but will not turn or plane into corners or angles. Hence the invention of the tool of V-section, and the swivel tool-holder. The round tool-holders are made right- and left-handed, the swivel tool-holder has a universal movement. The amount of projection of the round tool points is very limited, which impairs their utility when some overhanging of the tool is necessary. The V-tools can be slid out in their holders to operate on faces and edges situated to some considerable distance inwards from the end of the tool-holder.

Box Tools.—In one feature the box tools of the turret lathes resemble tool-holders. The small pieces of steel used for tool points are gripped in the boxes, as in tool-holders, and all the advantages which are derived from this arrangement of separating the point from its holder are thus secured (fig. 7). But in all other

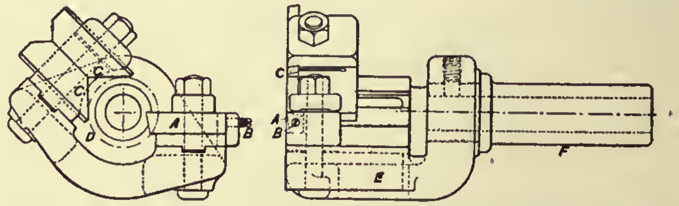

FIG. 7.—Box Tool for Turret Lathe. (Alfred Herbert, Ltd., Coventry.)

A, Cutting tool. *B*, Screw for adjusting radius of cut. *C C*, V-steadies supporting the work in opposition to *A*. *D*, Diameter of work. *E*, Body of holder. *F*, Stem which fits in the turret.

respects the two are dissimilar. Two or three tool-holders of different sizes take all the tool points used in a lathe, but a new box has to be devised in the case of almost every new job, with the exception of those the principal formation of which is the turning down of plain bars. The explanation is that, instead of a single point, several are commonly carried in a box. As complexity increases with the number of tools, new designs and dimensions of boxes become necessary, even though there may be family resemblances in groups. A result is that there is not, nor can there be, anything like finality in these designs. Turret work has become one of the most highly specialized departments of machine-shop practice, and the design of these boxes is already the work of specialists. More and more of the work of the common lathe is being constantly appropriated by the semi- and full-automatic machines, a result to which the magazine feeds for castings and forgings that cannot pass through a hollow spindle have contributed greatly. New work is constantly being attacked in the automatic machines that was deemed impracticable a short time before; some of the commoner jobs are produced with greater economy, while heavier castings and forgings, longer and larger bars, are tooled in the turret lathes. A great deal of the efficiency of the box tools is due to the support which is afforded to the cutting edges in opposition to the stress of cutting. V-blocks are introduced in most cases as in fig. 7, and these not only resist the stress of the cutting, but gauge the diameter exactly.

Shearing Action.—In many tools a shearing operation takes place, by which the stress of cutting is lessened. Though not very apparent, it is present in the round-nosed roughing tools, in the knife tools, in most milling cutters, as well as in all the shearing tools proper—the scissors, shears, &c.

Planes.—We pass by the familiar great chisel group, used by woodworkers, with a brief notice. Generally the tool angles of these lie between 15° and 25°. They include the chisels proper, and the gouges in numerous shapes and proportions, used by carpenters, cabinet-makers, turners, stone-masons and allied tradesmen. These are mostly thrust by hand to their work, without any mechanical control. Other chisels are used percussively, as the stout mortise chisels, some of the gouges, the axes, adzes and stone-mason's tools. The large family of planes embody chisels coerced by the mechanical control of the wooden (fig. 8) or metal stock. These also differ

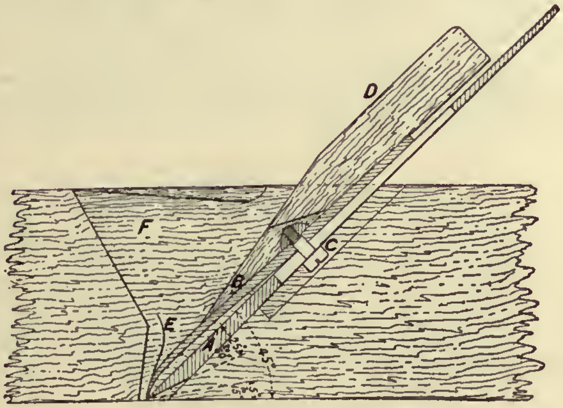

FIG. 8.—Section through Plane.

A, Cutting iron. *B*, Top or back iron. *C*, Clamping screw. *D*, Wedge. *E*, Broken shaving. *F*, Mouth.

from the chisels proper in the fact that the face of the cutting iron does not coincide with the face of the material being cut, but lies at an angle therewith, the stock of the plane exercising the necessary coercion. We also meet with the function of the top or non-cutting

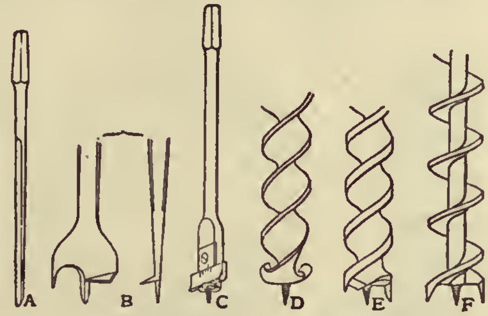

FIG. 9.—Group of Wood-boring Bits.

iron in breaking the shaving and conferring rigidity upon the cutting iron. This rigidity is of similar value in cutting wood as in cutting metal though in a less marked degree.

Drilling and Boring Tools.—Metal and timber are bored with equal facility; the tools (figs. 9 and 10) embody similar differences to the cutting tools already instanced for wood and metal. All the wood-working bits are true cutting tools, and their angles, if analysed, will be found not to differ much from those of the razor and common chisel. The drills for metal furnish examples both of scrapers and cutting tools. The common drill is only a scraper, but all the twist drills cut with good incisive action. An advantage possessed by all drills is that the cutting forces are balanced on each side of the centre of rotation. The same action is embodied in the best wood-boring bits and augers, as the Jennings, the Gilpin and the Irwin—much improved forms of the old centre-bit. But the balance is impaired if the lips are not absolutely symmetrical about the centre. This explains the necessity for the substitution of machine grinding for hand grinding of the lips, and great developments of twist drill grinding machines. Allied to the drills are the D-bits, and the reamers (fig. 11). The first-named both initiate and finish a hole;

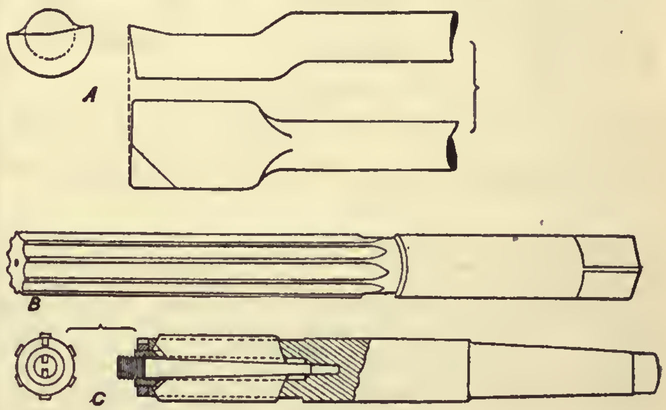

FIG. 11.

A, D-bit. *B*, Solid reamer. *C*, Adjustable reamer, having six flat blades forced outward by the tapered plug. Two lock-nuts at the end fix the blades firmly after adjustment.

the second are used only for smoothing and enlarging drilled holes, and for correcting holes which pass through adjacent castings or plates. The reamers remove only a mere film, and their action is that of scraping. The foregoing are examples of tools operated from one end and unsupported at the other, except in so far as they receive support within the work. One of the objectionable features of tools operated in this way is that they tend to "follow the hole," and if this is cored, or rough-drilled out of truth, there is risk of the boring tools following it to some extent at least. With the one exception of the D-bit there is no tool which can be relied on to take out a long bore with more than an approximation to concentricity throughout. Boring tools (fig. 12) held in the slide-rest will spring and bend and chatter, and unless the lathe is true, or careful compensation is made for its want of truth, they will bore bigger at one end than the other. Boring tools thrust by the back centre are liable to wabble, and though they are variously coerced to prevent them from turning round, that does not check the to-and-fro wabbly

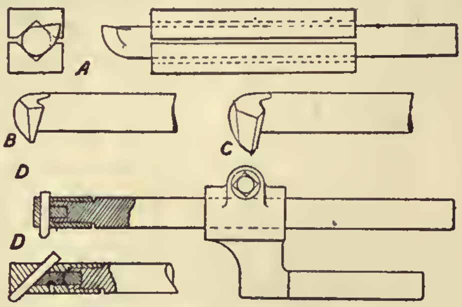

FIG. 12.—Group of Boring Tools.

A, Round boring tool held in V-blocks on slide-rest. *B*, *C*, Square and V-pointed boring tools. *D*, Boring bar with removable cutters, held straight, or angularly.

motion from following the core, or rough bore. In a purely reaming tool this is permitted, but it is not good in tools that have to initiate the hole.

This brings us to the large class of boring tools which are supported at each end by being held in bars carried between centres. There are two main varieties: in one the cutters are fixed directly in the bar (fig. 13, *A* to *D*), in the other in a head fitted on the bar (fig. 13, *E*), hence termed a "boring head." As lathe heads are fixed, the traverse cannot be imparted to the bars as in boring machines. The boring heads can be traversed, or the work can be traversed by the mechanism of the lathe saddle. The latter must be done when cutters are fixed in bars. A great deal of difference exists in the details of the fittings both of bars and heads, but they are not so arbitrary as they might seem at first sight. The principal differences are those due to the number of cutters used, their shapes, and their method of fastening. Bars receiving their cutters direct include one, two or four, cutting on opposite sides, and therefore balanced. Four give better balance than two, the cutters being set at right angles. If a rough hole runs out of truth, a single cutter is better than a double-ended one, provided a tool of the roughing shape is used. The shape of the tools varies from roughing to finishing, and their method of attachment is by screws, wedges or nuts, but we cannot illustrate the numerous differences that are met with.

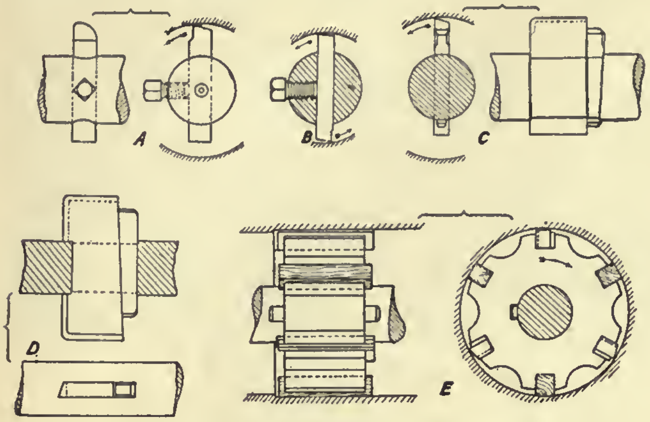

FIG. 13.—Group of Supported Boring Tools.

Saws.—The saws are a natural connecting link between the chisels and the milling cutters. Saws are used for wood, metal and stone. Slabs of steel several inches in thickness are sawn through as readily as, though more slowly than, timber planks. Circular and band saws are common in the smithy and the boiler and machine shops for cutting off bars, forgings and rolled sections. But the tooth shapes are not those used for timber, nor is the cutting speed the same. In the individual saw-teeth both cutting and scraping actions are illustrated (fig. 14). Saws which cut timber continuously with the grain, as rip, hand, band, circular, have incisive teeth. For though many are destitute of front rake, the method of sharpening at an angle imparts a true shearing cut. But all cross-cutting teeth scrape only, the teeth being either of triangular or of M-form, variously modified. Teeth for metal cutting also act strictly by scraping. The pitching of the teeth is related to the nature of the material and the direction of cutting. It is coarser for timber than for metal, coarser for ripping or sawing with the grain than for cross cutting, coarser for soft than for hard woods. The *setting* of teeth, or the bending over to right and left, by which the clearance is provided for the blade of the saw, is subject to similar variations. It is greatest for soft woods and least for metals, where in fact the clearance is often secured without set, by merely thinning the blade backwards. But it is greater for cross cutting than for ripping timber. Gulleting follows similar rules. The softer the timber, the greater the gulleting, to permit the dust to escape freely.

Milling Cutters.—Between a circular saw for cutting metal and a thin milling cutter there is no essential difference. Increase the thickness as if to produce a very wide saw, and the essential plain edge milling cutter for metal results. In its simplest form the milling cutter is a cylinder with teeth lying across its periphery, or parallel with its axis—the *edge mill* (fig. 15), or else a disk with teeth radiating on its face, or at right angles with its axis—the *end mill* (fig. 16). Each is used indifferently for producing flat faces and edges, and for cutting grooves which are rectangular in cross-section. These milling cutters invade the province of the single-edged tools of the planer, shaper and slotter. Of these two typical forms the

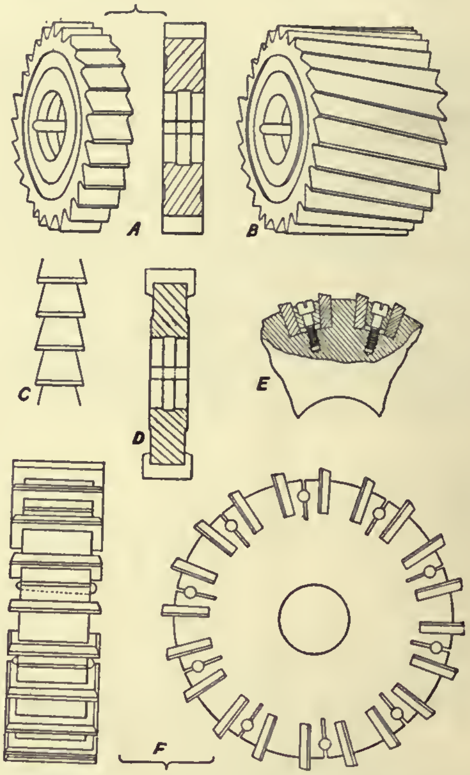

FIG. 15.—Group of Milling Cutters.

changes are rung in great variety, ranging from the narrow slitting tools which saw off bars, to the broad cutters of 24 in. or more in width, used on plano-millers.

When more than about an inch in width, surfacing cylindrical cutters are formed with spiral teeth (fig. 15, B), a device which is

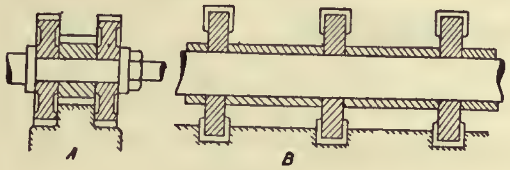

FIG. 17.

A, Straddle Mill, cutting faces and edges.

C, Double Slope Mill, with unequal angles.

essential to sweetness of operation, the action being that of shearing. These have their teeth cut on universal machines, using the dividing and spiral head and suitable change wheels, and after hardening they are sharpened on universal grinders. When cutters exceed about 6 in. in length the difficulties of hardening and grinding render the "gang" arrangement more suitable. Thus, two, three or more similar edge mills are set end to end on an arbor, with the spiral teeth running in reverse directions, giving a broad face with balanced endlong cutting forces. From these are built up the numerous gang mills, comprising plane faces at right angles with each other, of which the straddle mills are the best known (fig. 17, A). A common element in these combinations is the key seat type B having teeth on the periphery and on both faces as in fig. 15, C, D. By these combinations half a dozen faces or more can be tooled simultaneously, and all alike, as long as the mills retain their edge. The advantages over the work of the planer in this class of work are seen in tooling the faces and edges of machine tables, beds and slides, in shaping the faces and edges of caps to fit their bearing blocks. In a single cutter of the face type, but having teeth on back and edge also, T-slots are readily milled (fig. 16, D); this if done on the planer would require re-settings of awkwardly cranked tools, and more measurement and testing with templets than is required on a milling machine.

When angles, curves and profile sections are introduced, the capacity of the milling cutter is infinitely increased. The making of the cutters is also more difficult. Angular cutters (fig. 18) are used for producing the teeth of the mills themselves, for shaping the teeth of ratchet wheels, and, in combination with straight cutters in gangs, for angular sections. With curves, or angles and curves in combination, taps, reamers and drills can be fluted or grooved, the teeth of wheels shaped, and in fact any outlines imparted (fig. 19). Here the work of the fitter, as well as that of the planing and allied machines, is invaded, for much of this work if prepared on these machines would have to be finished laboriously by the file.

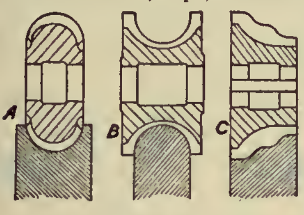

FIG. 19.
A, Convex Cutter.
B, Concave Cutter.
C, Profile Cutter.

There are two ways in which milling cutters are used, by which their value is extended; one is to transfer some of their work proper to the lathe and boring machine, the other is by duplication. A good many light circular sections, as wheel rims, hitherto done in lathes, are regularly prepared in the milling machine, gang mills being used for tooling the periphery and edges at once, and the wheel blank being rotated. Similarly, holes are bored by a rotating mill of the cylindrical type. Internal screw threads are done similarly. Duplication occurs when milling sprocket wheels in line, or side by side, in milling nuts on an arbor, in milling a number of narrow faces arranged side by side, in cutting the teeth of several spur-wheels on one arbor and in milling the teeth of racks several at a time.

One of the greatest advances in the practice of milling was that of making backed-off cutters. The sectional shape behind the tooth face is continued identical in form with the profile of the edge, the outline being carried back as a curve equal in radius to that of the cutting edge (fig. 20). The result is that the cutter may be sharpened on the front faces of the teeth without interfering with the shape which will be milled, because the periphery is always constant in outline. After repeated sharpenings the teeth would assume the form indicated by the shaded portion on two of the teeth. The limit of grinding is reached when the tooth becomes too thin and weak to stand up to its work. But such cutters will endure weeks or months of constant service before becoming useless. The chief advantage of backing-off or relieving is in its application to cutters of intricate curves, which would be difficult or impossible to sharpen along their edges. Such cutters, moreover, if made with ordinary teeth would soon be worn down, and be much weaker than the strong form of teeth represented in fig. 20. The relieving is usually done in special lathes, employing a profile tool which cuts the surface

of the teeth back at the required radius. Relieved cutters can of course be strung together on a single arbor to form gang mills, by which very complicated profiles may be tooled, beyond the capacity of a single solid mill.

Scrapes.—The tools which operate by scraping (fig. 21) include many of the broad finishing tools of the turner in wood and metal (cf. fig. 2), and the scrape of the wood worker and the fitter. The practice of scraping surfaces true, applied to surface plates, machine slides and similar objects, was due to Sir Joseph Whitworth. It superseded the older and less accurate practice of grinding to a mutual fit. Now, with machines of precision, the practice of grinding has to a large extent displaced the more costly scraping. Scraping is, however, the only method available when the most perfect contact is desired. Its advantage lies in the fact that the efforts of the workman can be localized over the smallest areas, and nearly infinitesimal amounts removed, a mere fine dust in the last stages.

Files.—These must in strictness be classed with scrapes, for, although the points are keen, there is never any front rake. Collectively there is a shearing action because the rows of teeth are cut diagonally. The sectional forms (fig. 22) and the longitudinal forms (fig. 23) of the files are numerous, to adapt them to all classes of work. In addition, the method of cutting, and the degrees of coarseness of the teeth, vary, being single, or float cut, or double cut (fig. 24). The rasps are another group. Degrees of coarseness are designated as rough, middle cut, bastard cut, second cut, smooth, double dead smooth; the first named is the coarsest, the last the finest. The terms are relative, since the larger a file is the coarser are its teeth, though of the same name as the teeth in a shorter file, which are finer.

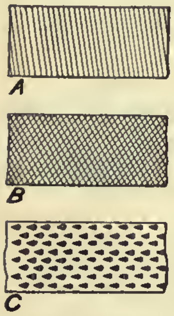

FIG. 24.—File Teeth.

A, Float cut.
B, Double cut.
C, Rasp cut.

Screwing Tools.—The forms of these will be found discussed under SCREW. They can scarcely be ranked among cutting tools, yet the best kinds remove metal with ease. This is due in great measure to the good clearance allowed, and to the narrowness of the cutting portions. Front rake is generally absent, though in some of the best screwing dies there is a slight amount.

Shears and Punches.—These may be of cutting or non-cutting types. Shears (fig. 25) have no front rake, but only a slight clearance. They generally give a slight shearing cut, because the blades do not lie parallel, but the cutting begins at one end and continues in detail to the other. But strictly the shears, like the punches, act by a severe detrusive effort; for the punch, with its bolster (fig. 26), forms a pair of cylindrical shears. Hence a shorn or punched edge is always rough, ragged, and covered with minute, shallow cracks. Both processes are therefore dangerous to iron and steel. The metal being unequally stressed, fracture starts in the annulus of metal. Hence the advantage of the practice of reamering out this annulus, which is completely removed by enlargement by about an ⅛ in. diameter, so that homogeneous metal is left throughout the entire unpunched section. The same results follow reamering both in iron and steel. Annealing, according to many experiments, has the same effect as reamering, due to the rearrangement of the molecules of metal. The perfect practice with punched plates is to punch, reamer, and finally to anneal. The effect of shearing is practically identical with that of punching, and planing and annealing shorn edges has the same influence as reamering and annealing punched holes.

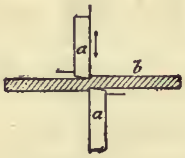

FIG. 25.—Shear Blades.

a, *a*, Blades.
b, Plate being sheared.

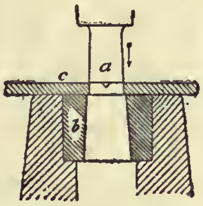

FIG. 26.—Punching.

a, Punch. *b*, Bolster.
c, Plate being punched.

Hammers.—These form an immense group, termed percussive, from the manner of their use (fig. 27). Every trade has its own peculiar shapes, the total of which number many scores, each with its own appropriate name, and ranging in size from the minute forms of the jeweler to the sledges of the smith and boiler maker and the planishing hammers of the coppersmith. Wooden hammers are termed mallets, their purpose being to avoid bruising tools or the surfaces of work. Most trades use mallets of some form or another. Hammer handles are rigid in all cases except certain percussive tools of the smithy, which are handled with withy rods, or iron rods flexibly attached to the tools, so that when struck by the sledge they shall not jar the hands. The fullering tools, and flatters, and setts, though not hammers strictly, are actuated by percussion. The dies of the die forgers are actuated percussively, being closed by powerful hammers. The action of caulking tools is percussive, and so is that of moulders' rammers.

Moulding Tools.—This is a group of tools which, actuated either by simple pressure or percussively, mould, shape and model forms in the sand of the moulder, in the metal of the smith, and in press work. All the tools of the moulder (fig. 28) with the exception of the rammers and vent wires act by moulding the sand into shapes by pressure. Their contours correspond with the plane and curved surfaces of moulds, and with the requirements of shallow and deep work. They are made in iron and brass. The fullers, swages and flatters of the smith, and the dies used with hammer and presses, all mould by percussion or by pressure, the work taking the counterpart of the dies, or of some portion of them. The practice of die forging consists almost wholly of moulding processes.

K, Pipe smoother.

Tool Steels.—These now include three kinds. The common steel, the controlling element in which is carbon, requires to be hardened and tempered, and must not be overheated, about 500° F. being the highest temperature permissible—the *critical* temperature. Actually this is seldom allowed to be reached. The disadvantage of this steel is that its capabilities are limited, because the heat generated by heavy cutting soon spoils the tools. The second is the Mushet steel, invented by R. F. Mushet in 1868, a carbon steel, in which the controlling element is tungsten, of which it contains from about 5 to 8%. It is termed *self-hardening*, because it is cooled in air instead of being quenched in water. Its value consists in its endurance at high temperatures, even at a low red heat. Until the advent of the high-speed steels, Mushet steel was reserved for all heavy cutting, and for tooling hard tough steels. It is made in six different tempers suitable for various kinds of duty. Tools of Mushet steel must not be forged below a red heat. It is hardened by reheating the end to a white heat, and blowing cold in an air blast. The third kind of steel is termed *high-speed*, because much higher cutting speeds are practicable with these than with other steels. Tools made of them are hardened in a blast of cold air. The controlling elements are numerous and vary in the practice of different manufacturers, to render the tools adaptable to cutting various classes of metals and alloys. Tungsten is the principal controlling element, but chromium is essential, and molybdenum and vanadium are often found of value. The steels are forged at a yellow tint, equal to about 1850° F. They are raised to a white heat for hardening, and cooled in an air blast to a bright red. They are then often quenched in a bath of oil.

The first public demonstration of the capacities of high speed steels was made at the Paris Exhibition of 1900. Since that time great advances have been made. It has been found that the section of the shaving limits the practicable speeds, so that, although cutting speeds of 300 and 400 ft. a minute are practicable with light cuts, it is more economical to limit speeds to less than 100 ft. per minute with much heavier cuts. The use of water is not absolutely essential as in using tools of carbon steel. The new steels show to much greater advantage on mild steel than on cast iron. They are more useful for roughing down than for finishing. The removal of 20 lb of cuttings per minute with a single tool is common, and that amount is often exceeded, so that a lathe soon becomes half buried in turnings unless they are carted away. The horse-power absorbed is proportionately large. Ordinary heavy lathes will take from 40 to 60 h.p. to drive them, or from four to six times more than is required by lathes of the same centres using carbon steel tools. Many remarkable records have been given of the capacities of the new steels. Not only turning and planing tools but drills and milling cutters are now regularly made of them. It is a revelation to see these drills in their rapid descent through metal. A drill of 1 in. in diameter will easily go through 5 in. thickness of steel in one minute.

Machine Tools

The machine tools employed in modern engineering factories number many hundreds of well-defined and separate types. Besides these, there are hundreds more designed for special functions, and adapted only to the work of firms who handle specialities. Most of the first named and many of the latter admit of grouping in classes. The following is a natural classification:

I. *Turning Lathes.*—These, by common consent, stand as a class alone. The cardinal feature by which they are distinguished is that the work being operated on rotates against a tool which is held in a rigid fixture—the rest. The axis of rotation may be horizontal or vertical.

II. *Reciprocating Machines.*—The feature by which these are characterized is that the relative movements of tool and work take place in straight lines, to and fro. The reciprocations may occur in horizontal or vertical planes.

III. *Machines which Drill and Bore Holes.*—These have some features in common with the lathes, inasmuch as drilling and boring are often done in the lathes, and some facing and turning in the drilling and boring machines, but they have become highly differentiated. In the foregoing groups tools having either single or double cutting edges are used.

IV. *Milling Machines.*—This group uses cutters having teeth arranged equidistantly round a cylindrical body, and may therefore be likened to saws of considerable thickness. The cutters rotate over or against work, between which and the cutters a relative movement of travel takes place, and they may therefore be likened to reciprocating machines, in which a revolving cutter takes the place of a single-edged one.

V. *Machines for Cutting the Teeth of Gear-wheels.*—These comprise two sub-groups, the older type in which rotary milling cutters are used, and the later type in which reciprocating single-edged tools are employed. Sub-classes are designed for one kind of gear only, as spur-wheels, bevels, worms, racks, &c.

VI. *Grinding Machinery.*—This is a large and constantly extending group, largely the development of recent years. Though emery grinding has been practised in crude fashion for a century, the difference in the old and the new methods lies in the embodiment of the grinding wheel in machines of high precision, and in the rivalry of the wheels of corundum, carborundum and alundum, prepared in the electric furnace with those of emery.

VII. *Sawing Machines.*—In modern practice these take an important part in cutting iron, steel and brass. Few shops are without them, and they are numbered by dozens in some establishments. They include circular saws for hot and cold metal, band saws and hack saws.

VIII. *Shearing and Punching Machines.*—These occupy a border line between the cutting and non-cutting tools. Some must be classed with the first, others with the second. The detrusive action also is an important element, more especially in the punches.

IX. *Hammers and Presses.*—Here there is a percussive action in the hammers, and a purely squeezing one in the presses. Both are made capable of exerting immense pressures, but the latter are far more powerful than the former.

X. *Portable Tools.*—This large group can best be classified by the common feature of being readily removable for operation on large pieces of erection that cannot be taken to the regular machines. Hence they are all comparatively small and light. Broadly they include diverse tools, capable of performing nearly the whole of the operations summarized in the preceding paragraphs.

XI. *Appliances.*—There is a very large number of articles which are neither tools nor machine tools, but which are indispensable to the work of these; that is, they do not cut, or shape, or mould, but they hold, or grip, or control, or aid in some way or other the carrying through of the work. Thus a screw wrench, an angle plate, a wedge, a piece of packing, a bolt, are appliances. In modern practice the appliance in the form of a templet or jig is one of the principal elements in the interchangeable system.

XII. *Wood-working Machines.*—This group does for the conversion of timber what the foregoing accomplish for metal. There is therefore much underlying similarity in many machines for wood and metal, but still greater differences, due to the conditions imposed on the one hand by the very soft, and on the other by the intensely hard, materials operated on in the two great groups.

XIII. *Measurement.*—To the scientific engineer, equally with the astronomer, the need for accurate measurement is of paramount importance. Neither good fitting nor interchangeability of parts is possible without a system of measurement, at once accurate and of ready and rapid application. Great advances have been made in this direction lately.

I.—Lathes

The popular conception of a lathe, derived from the familiar machine of the wood turner, would not give a correct idea of the lathe which has been developed as the engineer's machine tool. This has become differentiated into nearly fifty well-marked types, until in some cases even the term lathe has been dropped for more precise definitions, as vertical boring machine, automatic machine, while in others prefixes are necessary, as axle lathe, chucking lathe, cutting-off lathe, wheel lathe, and so on. With regard to size and mass the height of centres may range from 3 in. in the bench lathes to 9 or 10 ft. in gun lathes, and weights will range from say 50 lb to 200 tons, or more in exceptional cases. While in some the mechanism is the simplest possible, in others it is so complicated that only the specialist is able to grasp its details.

Early Lathes.—Space will not permit us to trace the evolution of the lathe from the ancient bow and card lathe and the pole lathe, in each of which the rotary movement was alternately forward, for cutting, and backward. The curious thing is that the wheel-driven lathe was a novelty so late as the 14th and 15th centuries, and had not wholly displaced the ancient forms even in the West in the 19th century, and the cord lathe still survives in the East. Another thing is that all the old lathes were of *dead centre*, instead of *running mandrel* type; and not until 1794 did the use of metal begin to take the place of wood in lathe construction. Henry Maudslay (1771–1831) did more than any other man to develop the engineer's self-acting lathe in regard to its essential mechanism, but it was, like its immediate successors for fifty years after, a skeleton-like, inefficient weakling by comparison with the lathes of the present time.

Broad Types.—A ready appreciation of the broad differences in lathe types may be obtained by considering the differences in the great groups of work on which lathes are designed to operate. Castings and forgings that are turned in lathes vary not only in size, but also in relative dimensions. Thus a long piece of driving shafting, or a railway axle, is very differently proportioned in length and diameter from a railway wheel or a wheel tire. Further, while the shaft has to be turned only, the wheel or the tire has to be turned and bored. Here then we have the first cardinal distinction between lathes, viz. those admitting work *between centres* (fig. 29) and *face* and *boring* lathes. In the first the piece of work is pivoted and driven between the centres of head-stock and tail-stock or loose poppet; in the second, it is held and gripped only by the dogs or jaws of a face-plate, on the head-stock spindle, the loose poppet being omitted.

These, however, are broad types only, since proportions of length to diameter differ, and with them lathe designs are modified whenever there is a sufficient amount of work of one class to justify the laying down of a special machine or machines to deal with it. Then further, we have duplicate designs, in which, for example, provision is made in one lathe for turning two or three long shafts simultaneously, or for turning and boring two wheels or tires at once. Further, the position of the axis of a face lathe need not be horizontal, as is necessary when the turning of long pieces has to be done between centres. There are obvious advantages in arranging it vertically, the principal being that castings and forgings can be more easily set and secured to a horizontal chuck than to one the face of which lies vertically. The chuck is also better supported, and higher rates of turning are practicable. In recent years these *vertical lathes* or vertical turning and boring mills (fig. 30) have been greatly increasing in numbers; they also occur in several designs to suit either general or special duties, some of them being used for boring only, as *chucking lathes.* Some are of immense size, capable of boring the field magnets of electric generators 40 ft. in diameter.

Standard Lathes.—But for doing what is termed the general work of the engineer's turnery, the standard lathes (fig. 29) predominate, *i.e.* self-acting, sliding and surfacing lathes with headstock, loose poppet and slide-rest, centres, face plates and chucks, and an equipment by which long pieces are turned, either between centres or on the face chucks, and bored. One of the greatest objections to the employment of these standard types of lathes for indiscriminate duty is due to the limited height of the centres or axis of the headstock, above the face of the bed. This is met generally by providing a *gap* or deep recess in the bed next the fast headstock, deep enough to take face work of large diameter. The device is very old and very common, but when the volume of work warrants the employment of separate lathes for face-work and for that done between centres it is better to have them.

Screw-cutting.—A most important section of the work of the engineer's turnery is that of cutting screws (see SCREW). This has resulted in differentiation fully as great as that existing between centres and face-work. The slide-rest was designed with this object, though it is also used for plain turning. The standard "self-acting sliding, surfacing and screw-cutting lathe" is essentially the standard turning lathe, with the addition of the screw-cutting mechanism. This includes a master screw—the *lead* or *guide screw,* which is gripped with a *clasp nut,* fastened to the travelling carriage of the slide-rest. The lead-screw is connected to the headstock spindle by *change wheels,* which are the variables through which the relative rates of movement of the spindle and the lead-screw, and therefore of the screw-cutting tool, held and traversed in the slide-rest, are effected. By this beautiful piece of mechanism a guide screw, the pitch of which is permanent, is made to cut screw-threads of an almost infinite number of possible pitches, both in whole and fractional numbers, by virtue of rearrangements of the variables, the change wheels. The objection to this method is that the trains of change wheels have to be recalculated and rearranged as often as a screw of a different pitch has to be cut, an operation which takes some little time. To avoid this, the *nest* or *cluster system* of gears has been largely adopted, its most successful embodiment being in the Hendey-Norton lathe. Here all the change wheels are arranged in a series permanently on one shaft underneath the headstock, and any one of them is put into engagement by a sliding pinion operated by the simple movement of a lever. Thus the lead-screw is driven at different rates without removing any wheel from its spindle. This has been extensively applied to both small and large lathes. But a moment's thought will show that even this device is too cumbrous when large numbers of small screws are required. There is, for example, little in common between the screw, say of 5 or 6 ft. in length, for a massive penstock or valve, and ½-in. bolts, or the small screws required in thousands for electrical fittings. Clearly while the self-acting screw-cutting lathe is the best possible machine to use for the first, it is unsuitable for the last. So here at once, from the point of view of screw cutting only, an important divergence takes place, and one which has ultimately led to very high specialization.

Small Screws.—When small screws and bolts are cut in

large quantities, the guide-screw and change wheels give place to other devices, one of which involves the use of a separate master-screw for every different pitch, the other that of encircling cutting instruments or *dies*. The first are represented by the *chasing lathe*, the second by the *screwing lathes* and *automatics*. Though the principles of operation are thus stated in brief, the details in design are most extensive and varied.

In a chasing lathe the master-screw or *hob*, which may be either at the rear of the headstock or in front of the slide-rest, receives a hollow clasp-nut or a half-nut, or a star-nut containing several pitches, which, partaking of the traverse movement of the screw-thread, imparts the same horizontal movement to the cutting tool. The latter is sometimes carried in a hinged holder, sometimes in a common slide-rest. The attendant throws it into engagement at the beginning of a traverse, and out when completed, and also changes the hobs for threads of different sections. The screwed stays of locomotive fire-boxes are almost invariably cut on chasing lathes of this class.

In the screwing machines the thread is cut with dies, which encircle the rotating bar; or alternatively the dies rotate round a fixed pipe, and generally the angular *lead* or advance of the thread draws the dies along. These dies differ in no essentials from similar tools operated by a hand lever at the bench. There are many modifications of these lathes, because the work is so highly specialized that they are seldom used for anything except the work of cutting screws varying but little in dimensions. Such being the case they can hardly be classed as lathes, and are often termed screwing machines, because no provision exists for preliminary turning work, which is then done elsewhere, the task of turning and threading being divided between two lathes. In some cases this is an economical system, but in others not. It cannot be considered so when bolts, screws and allied forms are of small dimensions.

Hollow Mandrel Lathes.—It has been the growing practice since the last decade of the 19th century to produce short articles, required in large quantities, from a long bar. This involves making the lathe with a hollow mandrel; that is, the mandrel of the headstock has a hole drilled right through it, large enough to permit of the passage through it of the largest bar which the class of work requires. Thus, if the largest section of the finished pieces should require a bar of $1\frac{1}{2}$ in. diameter, the hole in the mandrel would be made $1\frac{5}{8}$ in. Then the bar, inserted from the rear-end, is gripped by a chuck or *collet* at the front, the operations of turning, screwing and cutting off done, and the bar then thrust farther through to the exact length for the next set of identical operations to be performed, and so on. This mechanism is termed a *wire feed*, because the first lathes which were built of this type only operated on large wires; the heavy bar lathes have been subsequently developed from it. In the more advanced types of lathes this feeding through the hollow spindle does not require the intervention of the attendant, but is performed automatically.

The amount of preliminary work which has to be done upon a portion of a bar before it is ready for screwing varies. The simplest object is a stud, which is a parallel piece screwed up from each end. A bolt is a screw with a head of hexagonal, square or circular form, and the production of this involves turning the shank and shoulder and imparting convexity to the end, as well as screwing. But screw-threads have often to be cut on objects which are not primarily bolts, but which are spindles of various kinds used on mechanisms and machine tools, and in which reductions in the form

O, Cone pulley belted up to *P*, for driving the feeds of saddle and down-slide.

of steps have to be made, and recesses, or flanges, or other features produced. Out of the demands for this more complicated work, as well as for plain bolts and studs, has arisen the great group of *turret* or *capstan lathes* (fig. 31) and the automatics or *automatic screw machines* which are a high development of the turret lathes.

Turret Lathes.—The turret or capstan (fig. 32) is a device for gripping as many separate tools as there are distinct operations to be performed on a piece of work; the number ranges from four to as many as twenty in some highly elaborated machines, but five or six is the usual number of holes. These tools are brought round

in due succession, each one doing its little share of work, until the cycle of operations required to produce the object is complete, the cycle including such operations as turning and screwing, roughing and finishing cuts, drilling and boring. Severance of the finished piece is generally done by a tool or tools held by a *cross-slide* between the headstock and turret, so termed because its movements take place at right angles with the axis of the machine. This also often performs the duty of "forming," by which is meant the shaping of the exterior portion of an object of irregular outline, by a tool the edge of which is an exact counterpart of the profile required. The exterior of a cycle hub is shaped thus, as also are numerous handles and other objects involving various curves and shoulders, &c. The tool is fed perpendicularly to the axis of the rotating work and completes outlines at once; if this were done in ordinary lathes much tedious manipulation of separate tools would be involved.

Automatics.—But the marvel of the modern automatics (fig. 33) lies in the mechanism by which the cycle of operations is rendered absolutely independent of attendance, beyond the first adjustments and the insertion of a fresh bar as often as the previous one becomes used up. The movements of the rotating turret and of the cross-slide, and the feeding of the bar through the hollow spindle, take place within a second, at the conclusion of the operation preceding. These movements are effected by a set of mechanism independent of that by which the headstock spindle is rotated, viz. by cams or cam drums on a horizontal cam shaft, or other equivalent device, differing much in arrangement, but not principle. Movements are hastened or retarded, or pauses of some moments may ensue, according to the cam arrangements devised, which of course have to be varied for pieces of different proportions and dimensions. But when the machines with their tools are once set up, they will run for days or weeks, repeating precisely the same cycle of operations; they are self-lubricating, and only require to be fed with fresh lengths of bar and to have their tools resharpened occasionally. Of these automatics alone there are something like a dozen distinct types, some with their turrets vertical, others horizontal. Not only so but the use of a single spindle is not always deemed sufficiently economical, and some of these designs now have two, three and four separate work spindles grouped in one head.

Specialized Lathes.—Outside of these main types of lathes there are a large number which do not admit of group classification. They are designed for special duties, and only a representative list can be given. Lathes for turning tapered work form a limited

number, and they include the usual provisions for ordinary turning. In some designs change wheels are made use of for imparting a definite movement of cross traverse to the tool, which being compounded with the parallel sliding movements produces the taper. In others an upper bed carrying the heads and work swivels on a lower bed, which carries the slide rest. More often tapers are turned by a cross adjustment of the loose poppet, or by a taper attachment at the rear of the lathe, which coerces the movement of the top or tool-carrying slide of the rest. Or, as in short tapers, the slide-rest is set to the required angle on its carriage. Balls are sometimes turned by a spherical attachment to the slide-rest of an ordinary lathe. Copying lathes are those in which an object is reproduced from a pattern precisely like the objects required. The commonest example is that in which gun-stocks and the spokes of wheels are turned, but these are used for timber, and the engineer's copying lathe uses a form or cam and a milling cutter. The form milling machine is the copying machine for metal-work. The manufacture of boilers has given birth to two kinds of lathes, one for turning the boiler ends, the other the boiler flue flanges, the edges of which have to be caulked. Shaft pulleys have appropriated a special lathe containing provision for turning the convexity of the faces. Lathes are duplicated in two or three ways. Two, four, six or eight tools sometimes operate simultaneously on a piece of work. Two lathes are mounted on one bed. A tool will be boring a hole while another is turning the edges of the same wheel. One will be boring, another turning a wheel tire, and so on. The rolls for iron and steel mills have special lathes for trueing them up. The thin sheet metal-work produced by spinning has given rise to a special kind of spinning lathe where pressure, and not cutting, is the method adopted.

Methods of Holding and Rotating Work. Chucks.—The term chuck signifies an appliance used in the lathe to hold and rotate work. As the dimensions and shapes of the latter vary extensively, so also do those of the chucks. Broadly, however, the latter correspond with the two principal classes of work done in the lathe, that *between centres*, and that held at one end only or *face work*. This of course is an extremely comprehensive classification, because chucks of the same name differ vastly when used in small and large lathes. The chucks, again, used in turret work, though they grip the work by one end only, differ entirely in design from the face chucks proper.

Chucking between Centres.—The simplest and by far the commonest method adopted is to drill countersunk centres at the ends of the work to be turned, in the centre or longitudinal axis (fig. 34, *A*), and support these on the point centres of headstock and poppet. The angle included by the centres is usually 60°, and the points may enter the work to depths ranging from as little as $\frac{1}{16}$ in. in very light pieces to $\frac{1}{2}$ in., $\frac{3}{4}$ in. or 1 in. in the heaviest. Obviously a piece centred thus cannot be rotated by the mere revolution of the lathe, but it has to be driven by some other agent making con-

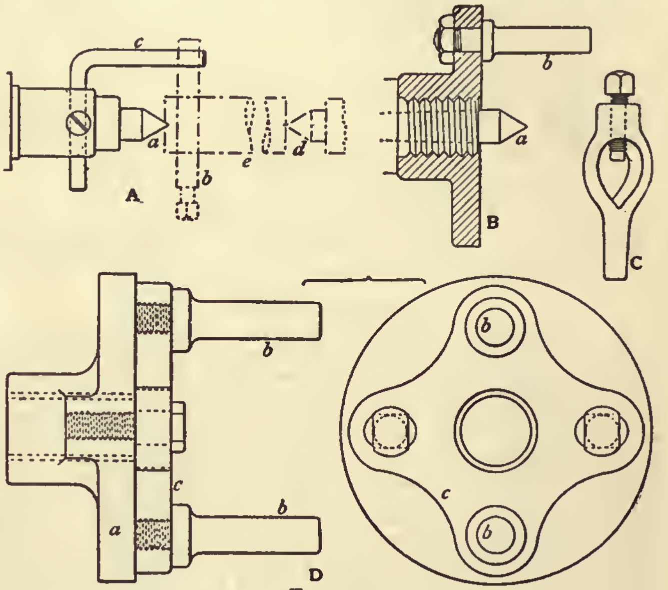

FIG. 34.

B, Face-plate driver or catch-plate; *a*, centre; *b*, driver.
C, Common heart-shaped carrier.
D, Clement double driver; *a*, face-plate; *b*, *b*, drivers; *c*, loose plate carrying drivers.

nexion between it and the mandrel. The wood turner uses a forked or prong centre to obtain the necessary leverage at the headstock end, but that would be useless in metal. A *driver* is therefore used, of which there are several forms (fig. 34), the essential element being a short stiff prong of metal set away from the centre, and rotating the work directly, or against a *carrier* which encircles and pinches the work. As this method of driving sets up an unbalanced force, the "Clement" or *double driver* (fig. 34, *D*), was invented, and is frequently made use of, though not nearly so much as the common single driver. In large and heavy work it is frequently the practice to drive in another way, by the dogs of the face-plate.

Steadies.—Pieces of work which are rigid enough to withstand the stress of cutting do not require any support except the centres.

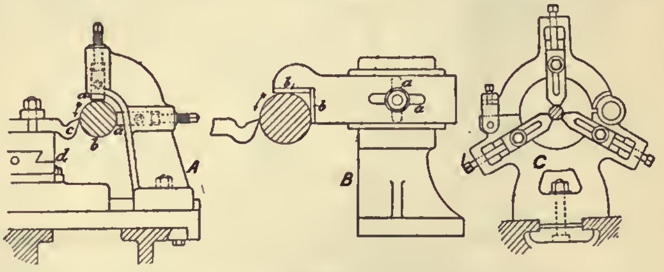

FIG. 35.

A, Travelling steady with adjustable studs *a*, *a*; *b*, work; *c*, tool; *d*, slide-rest.
B, Steady with horizontal and vertical adjustment through slotted bolt holes *a*, *a*; *b*, *b*, brass or steel facings.
C, Fixed steady with hinged top and three setting pieces.

But long and comparatively slender pieces have to be steadied at intermediate points (fig. 35). Of devices for this purpose there are many designs; some are *fixed* or bolted to the bed and are shifted when necessary to new positions, and others are bolted to the carriage of the slide-rest and move along with it—*travelling* *steadies*. In some the work is steadied in a vee, or a right angle, in others adjustable pins or arms are brought into contact with it. As the pressure of the cut would cause an upward as well as backward yielding of the work, these two movements are invariably provided against, no matter in what ways the details of the steadies are worked out. Before a steady can be used, a light cut has to be taken in the locality where the steady has to take its bearing, to render the work true in that place. The travelling steady follows immediately behind the tool, coming in contact therefore with finished work continually.

Mandrels.—Some kinds of work are carried between centres indirectly, upon mandrels or arbors (fig. 36). This is the method

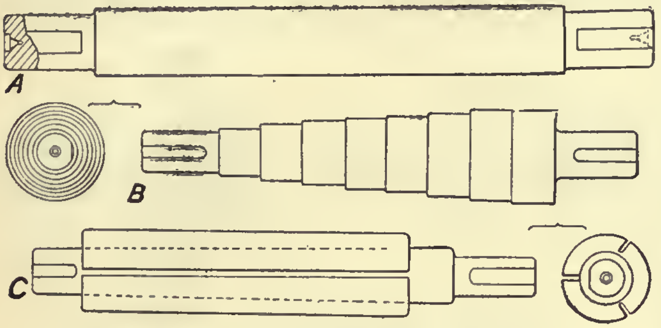

FIG. 36.—Mandrels.

A, Plain mandrel. *B*, Stepped mandrel. *C*, Expanding mandrel.

adopted when wheels, pulleys, bushes and similar articles are bored first and turned afterwards, being chucked by the bore hole, which fits on a mandrel. The latter is then driven between point centres and the bore fits the mandrel sufficiently tightly to resist the stress of turning. The large number of bores possible involves stocking a considerable number of mandrels of different diameters. As it is not usual to turn a mandrel as often as a piece of work requires chucking, economy is studied by the use of *stepped* mandrels, which comprise several diameters, say from three to a dozen. A better device is the *expanding* mandrel, of which there are several forms. The essential principle in all is the capacity for slight adjustments in diameter, amounting to from $\frac{1}{4}$ in. to $\frac{1}{2}$ in., by the utilization of a long taper. A split, springy cylinder may be moved endwise over a tapered body, or separate single keys or blades may be similarly moved.

Face-Work.—That kind of work in which support is given at the headstock end only, the centre of the movable poppet not being required, is known as face-work. It includes pieces the length of which ranges from something less than the diameter to about three or four times the diameter, the essential condition being that the unsupported end shall be sufficiently steady to resist the stress of cutting. Work which has to be bored, even though long, cannot be steadied on the back centre, and if long is often supported on a *cone plate*. The typical appliance used for face-work is the common *face-plate* (fig. 37). It is a plain disk, screwed on the mandrel

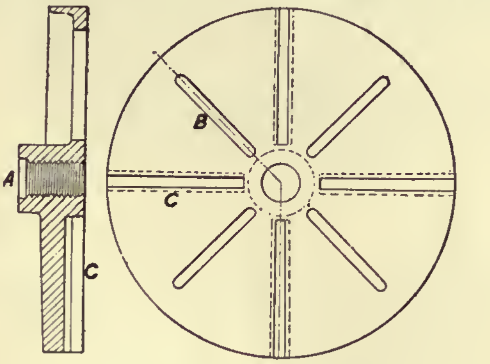

FIG. 37.—Face-plate.

A, Screwed hole to fit mandrel nose. *B*, Slots for common bolts. *C*, Tee-slots for tee-head bolts.

nose, and having slot holes in which bolts are inserted for the purpose of cramping pieces of work to its face. There are numerous forms of these clamps, and common bolts also are used. The face-plate may also serve to receive an intermediary, the *angle-plate*, against which work may be bolted when its shape is such as to render bolting directly to the plate inconvenient.

Jaw Chucks.—When a face-plate has fitted to it permanent *dogs* or *jaws* it is termed a dog or *jaw chuck* (fig. 38). In the commonest form the jaws are moved radially and independently, each by its own screw, to grip work either externally or internally. In some cases the dogs are loosely fitted to the holes in a plain face-plate. In all these types the radial setting is tentative, that is, the jaws being independent, there is no self-centring capacity, and thus much time is lost. A large group, therefore, are rendered self-centring by the turning of a ring which actuates a face scroll

(fig. 39) or a circular rack with pinions (fig. 40), turned with a key which operates all the jaws simultaneously inwards or outwards. But as some classes of jobs have to be adjusted eccentrically, many chucks are of the *combination* type (fig. 40), capable of being used independently or concentrically, hence termed *universal* chucks. The change from one to the other simply means throwing the ring of teeth out of or into engagement with the pinions by means of cams or equivalent devices. Each type of chuck occurs in a large range of dimensions to suit lathes of all centres, besides which every lathe includes several chucks, large and small, in its equipment. The range of diameters which can be taken by any one chuck is limited, though the jaws are made with steps, in addition to the range afforded by the operating screws. The "Taylor" spiral chucks (fig. 41) differ essentially from the scroll types in having the actuating threads set spirally on the sloping interior of a cone. The result is that the outward pressure of each jaw is received behind the body, because the spiral rises up at the back. In the ordinary scroll chucks the pressure is taken only at the bottom of each jaw, and the tendency to tilt and pull the teeth out of shape is very noticeable. The spiral, moreover, enables a stronger form of tooth to be used, together with a finer pitch of threads, so that the wearing area can be increased.

The foregoing may be termed the standard chucks. But in addition there are large numbers for dealing with special classes of work. Brass finishers have several. Most of the hollow spindle lathes and automatics have *draw-in* or *push-out* chucks, in which the jaws are operated simultaneously by the conical bore of the encircling nose, so that their action is instantaneous and self-centring. They are either operated by hand, as in fig. 31, or automatically, as in fig. 33. There is also a large group used for drills and reamers—the *drill chucks* employed in lathes as well as in drilling machines.

II.—Reciprocating Machine Tools

This is the only convenient head under which to group three great classes of machine tools which possess the feature of reciprocation in common. It includes the planing, shaping and slotting machines. The feature of reciprocation is that the cutting tool is operative only in one direction; that is, it cuts during one stroke or movement and is idle during the return stroke. It is, therefore, in precisely the same condition as a hand tool such as a chisel, a carpenter's plane or a hand saw. We shall return again to this feature of an idle stroke and discuss the devices that exist to avoid it.

Planing Machines.—In the standard planer for general shop purposes (fig. 42) the piece of work to be operated on is attached to a horizontal table moving to and fro on a rigid bed, and passing underneath the fixed cutting tool. The tool is gripped in a box having certain necessary adjustments and movements, so that the tool can be carried or *fed* transversely across the work, or at right angles with the direction of its travel, to take successive cuts, and also downwards or in a vertical direction. The tool-box is carried on a cross-slide which has capacity for several feet of vertical adjustment on upright members to suit work of varying depths. These uprights or *housings* are bolted to the sides of the bed, and the whole framing is so rigidly designed that no perceptible tremor or yielding takes place under the heaviest duty imposed by the stress of cutting.

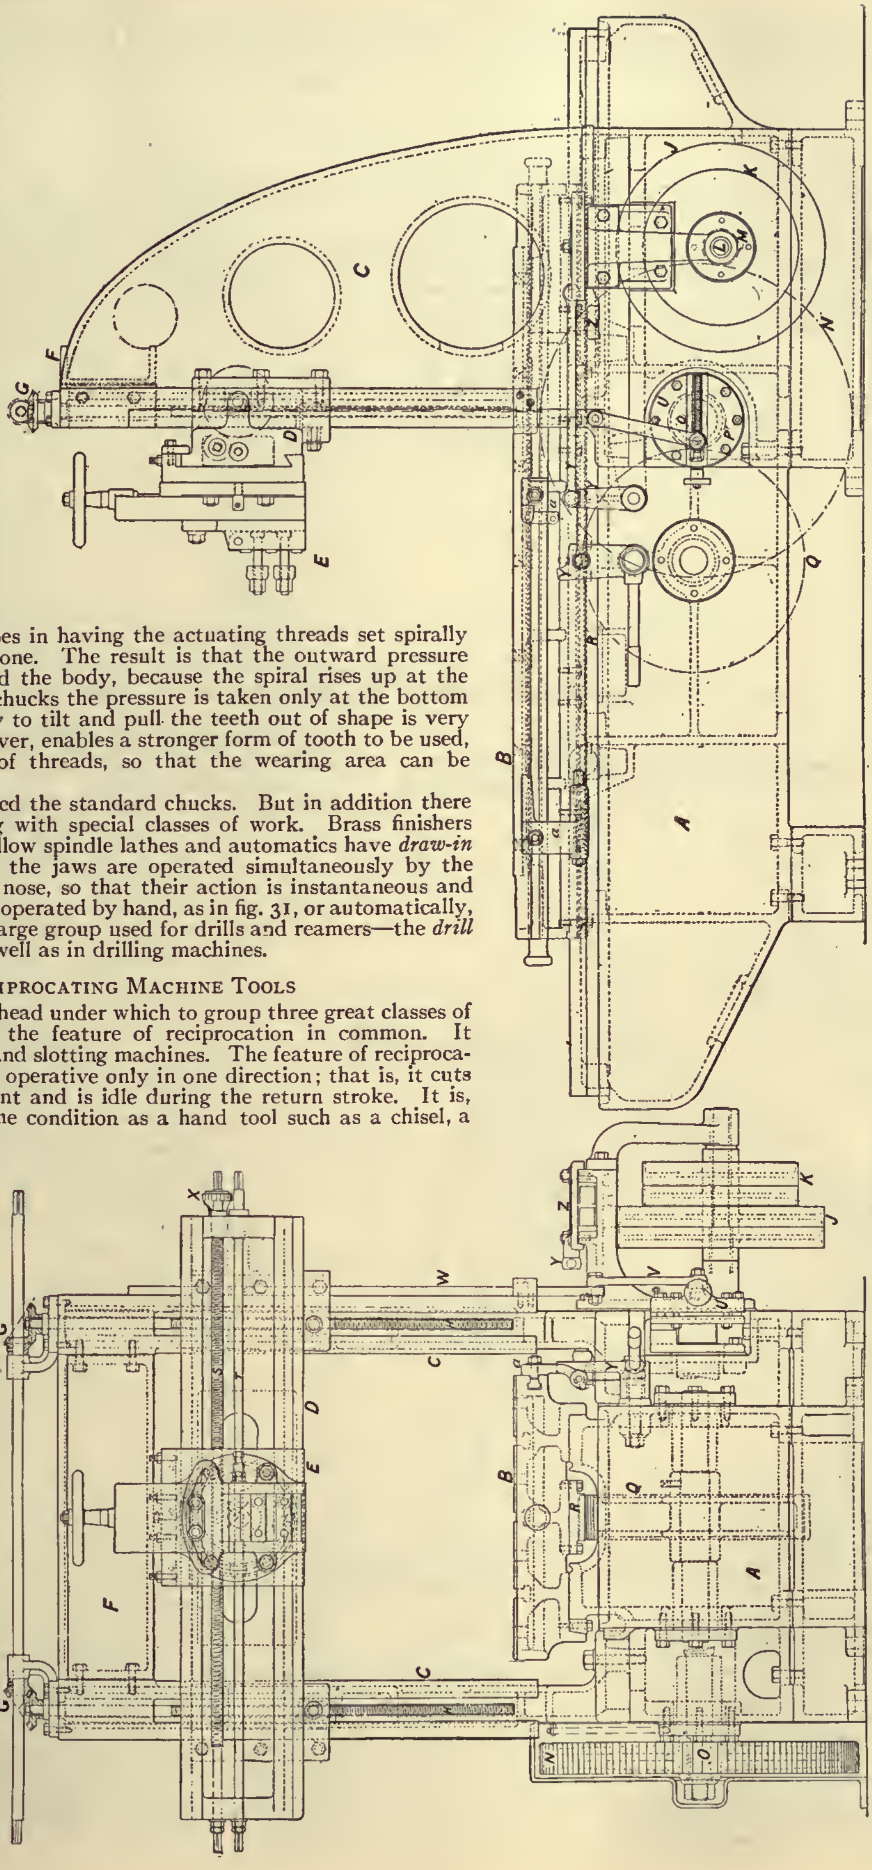

Fig. 42.—Planing Machine to take work 5 ft. in length × 2 ft. 6 in. wide × 2 ft. 6 in. in height. (Greenwood & Batley, Ltd., Leeds.)

B, Table.
C, *C*, Housings.
D, Cross-rail.
E, Tool-box.
F, Stretcher.
G, *G*, Bevel-gears for elevating cross-slide by means of screws *H*, *H*.
J, Fast and loose pulleys for driving the table during the cutting stroke.
K, Pulleys for non-cutting stroke.
L, Pulley shaft.
M, Pinion on ditto, driving wheel *N*.
O, Shaft of *N* carrying pinion *P*, which drives *Q*, engaging with the rack *R* on the underside of the table *B*.
S, Traverse screw actuating linear movement of tool-box, *E*.
T, Splined rod for actuating down-feed of tool-box.
U, Slotted feed disk rotated by shaft *O*.
V, Lever adjustable across disk.
W, Toothed rack reciprocated vertically by disk and lever, and operating feed gear-wheels on shafts *S* and *T*.
X, Ratchet feed.
a, *a*, Dogs adjustable in slot at the edge of the table *B*.
Y, *Y*, Levers actuated by dogs, and operating belt-shifting forks *Z*.

Moreover, after the required adjustments have been made and the machine started, the travel and the return of the work-table and the feeding of the tool across the surface are performed by self-acting mechanism actuated by the reciprocations of the table itself, the table being driven from the belt pulleys.

To such a design there are objections, which, though their importance has often been exaggerated, are yet real. First, the cross-rail and housings make a rigid enclosure over the table, which sometimes prevents the admission of a piece that is too large to pass under the cross-rail or between the housings. Out of this

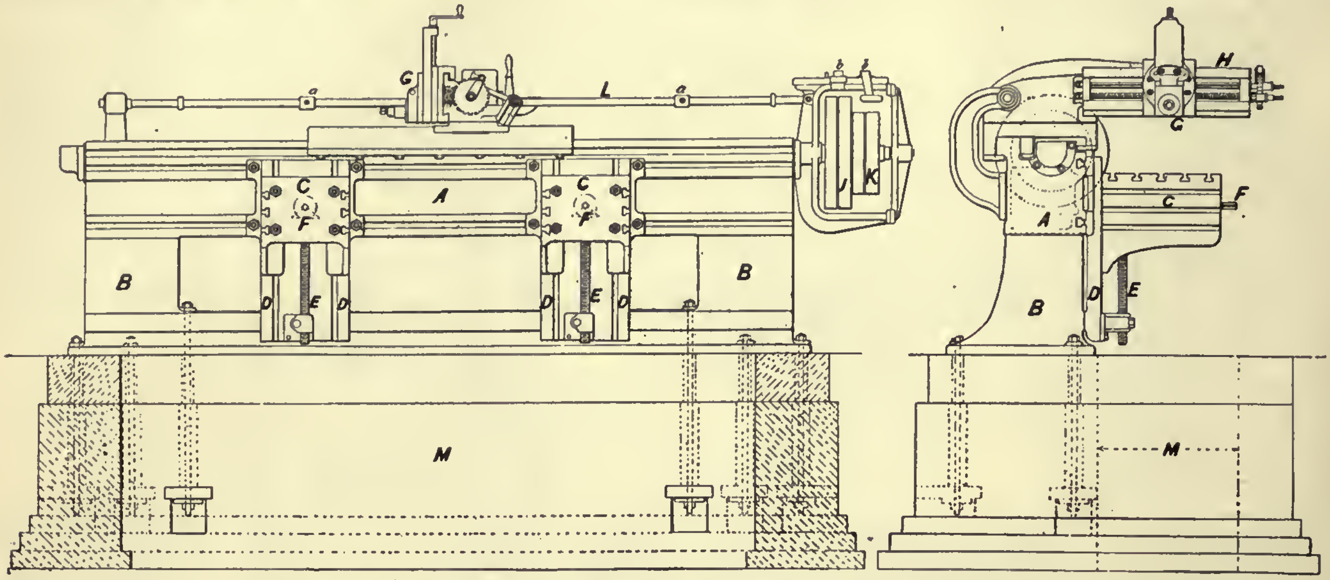

FIG. 43.—20-in. Side Planing Machine. (G. Richards & Co., Ltd., Manchester.)

b, Crank handle spindle for operating ditto.
c, Handle for actuating down feed of tool.
J, Driving cone pulley actuating pinion *d*, disk wheel *e*, with slotted disk, and adjustable nut moving in the slot of the crank *f*, which actuates the lever *g*, connected to the tool ram *G*, the motion constituting the Whitworth quick return; *g* is pivoted to a block which is adjustable along a slot in *G*, and the clamping of this block in the slot regulates the position of the ram *G*, to suit the position of the work on the table.
k, Feed disk driven by small gears from cone pulley.
j, Pawl driven from disk through levers at various rates, and controlling the amount of rotation of the feed screw *F*.
K, Conical mandrel for circular shaping, driven by worm and wheel *l*.

objection has arisen a new design, the *side planer* (fig. 43), in which the tool-box is carried by an arm movable along a fixed bed or base, and overhanging the work, which is fastened to the side of the base, or on angle brackets, or in a deep pit alongside. Here the important difference is that the work is not traversed under the tool as in the ordinary planer, but the tool moves over the work. But an evil results, due to the overhang of the tool arm, which being a cantilever supported at one end only is not so rigid when cutting as the cross-rail of the ordinary machine, supported at both ends on housings. The same idea is embodied in machines built in other respects on the reciprocating table model. Sometimes one housing is omitted, and the tool arm is carried on the other, being therefore unsupported at one end. Sometimes a housing is made to be removable at pleasure, to be temporarily taken away only when a piece of work of unusual dimensions has to be fixed on the table.

Another objection to the common planer is this. It seems unmechanical in this machine to reciprocate a heavy table and piece of work which often weighs several tons, and let the tool and its holder of a few hundredweights only remain stationary. The mere reversal of the table absorbs much greater horse-power than the actual work of cutting. Hence a strong case is often stated for the abandonment of the common practice. But, on the other hand, the centre of gravity of the moving table and work lies low down, while when the cross-rail and housings with the cutting tool are travelled and reversed, their centre of gravity is high, and great precautions have to be taken to ensure steadiness of movement. Several planers are made thus, but they are nearly all of extremely massive type—the *pit planers*. The device is seldom applied to those of small and medium dimensions.

But there is a great group of planers in which the work is always fixed, the tools travelling. These are the *wall planers*, *vertical planers* or *wall creepers*, used chiefly by marine engine builders. They are necessary, because many of the castings and forgings are too massive to be put on the tables of the largest standard machines. They are therefore laid on the base-plate of the wall planer, and the tool-box travels up and down a tall pillar bolted to the wall or standing independently, and so makes vertical cutting strokes. In some designs horizontal strokes are provided for, or either vertical or horizontal as required. Here, as in the side planer, there is no limitation whatever to the length of the work, since it may extend to any distance beyond the base-plate.

Shaping Machines.—The shaping machine (fig. 44) does for comparatively small pieces that which the planer does for long ones. It came later in time than the planer, being one of James Nasmyth's inventions, and beyond the fact that it has a reciprocating non-cutting return stroke it bears no resemblance to the older machine. Its design is briefly as follows: The piece of work to be shaped is attached to the top, or one of the vertical side faces, of a right-angled bracket or brackets. These are carried upon the face of a main standard and are adjustable thereon in horizontal and vertical directions. In small machines the ram or reciprocating arm (see fig. 44, *G*) slides in fixed guides on the top of the pillar, and the necessary side traverse is imparted to the work table *B*. To the top of the main standard, in one design, a carriage is fitted with horizontal traverse to cover the whole breadth, within the capacity of the machine, of any work to be operated on. In the largest machines two standards support a long bed, on which the carriage, with its ram, traverses past the work. These machines are frequently made double-headed, that is carriages, rams and work tables are duplicated, and the operator can set one piece of work while the other is being shaped. In all cases the movement of the reciprocating arm, to the outer end of which the tool is attached, takes place in a direction transversely to the direction of movement of the carriage, and the tool receives no support beyond that which it receives from the arm which overhangs the work. Hence the shaper labours under the same disadvantages as the side planer—it cannot operate over a great breadth. A shaper with a 24-in. stroke is one of large capacity, 16 in. being an average limit. Although the non-cutting stroke exists, as in the planer, the objection due to the mass of a reciprocating table does not exist, so that the problem does not assume the same magnitude as in the planer. The weak point in the shaper is the overhang of the arm, which renders it liable to spring, and renders heavy cutting difficult. Recently a novel design has been introduced to avoid this, the *draw-cut shaper*, in which the cutting is done on the inward or return stroke, instead of on the outward one.

Slotting Machines.—In the slotting machine (fig. 45) the cutting takes place vertically and there is a lost return stroke. All the

necessary movements save the simple reciprocating stroke are imparted to the compound table on which the work is carried. These include two linear movements at right angles with each other and a circular motion capable of making a complete circle. Frequently a tilting adjustment is included to permit of slotting at an angle. The slotting machine has the disadvantage of an arm unsupported beyond the guides in which it moves. But the compound movements of the table permit of the production of shapes which cannot be done on planers and shapers, as circular parts and circular arcs, in combination with straight portions. Narrow key grooves in the bores of wheels are also readily cut, the wheels lying on the horizontal table, which would only be possible on planer and shaper by the use of awkward angle brackets, and of specially projecting tools.

Quick return in planers is accomplished by having two distinct sets of gearing—a slow set for cutting and a quick train for return, each operated from the same group of driving pulleys. The return travel is thus accomplished usually three, often four, times more quickly than the forward rate; sometimes even higher rates are arranged for. In the shaper and slotter such acceleration is not practicable, a rate of two to one being about the limit, and this is obtained not by gears, but by the slotted crank, the *Whitworth return*, on shapers and slotters, or by elliptical toothed wheels on slotters. The small machines are generally unprovided with this acceleration.

The double-cutting device seems at first sight the best solution, and it is adopted on a number of machines, though still in a great minority. The pioneer device of this kind, the rotating tool-box of Whitworth, simply turns the tool round through an angle of 180° at the termination of each stroke, the movement being self-acting. In some later designs, instead of the box being rotated to reverse the tool. two tools are used set back to back, and the one that is not cutting is *relieved* for the time being, that is tilted to clear the work. Neither of these tools will plane up to a shoulder as will the ordinary ones.

Allied Machines.—The reciprocation of the tool or the work, generally the former, is adopted in several machines besides the standard types named. The plate-edge planer is used by platers and boiler makers. It is a side planer, the plates being bolted to a bed, and the tool traversing and cutting on one or both strokes. Provision is often included for planing edges at right angles. The key-seaters are a special type, designed mainly to remove the work of cutting key grooves in the bores of wheels and pulleys from the slotting machine. The work is fixed on a table and the keyway cutting tool is drawn downwards through the bore, with several resulting practical advantages. Many planing machines are portable so that they may be fixed upon very massive work. Several gear-wheel cutting machines embody the reciprocating tool.

III.—Drilling and Boring Machines

The strict distinction between the operations of drilling and boring is that the first initiates a hole, while the second enlarges one already existing. But the terms are used with some latitude. A combined drilling and boring machine is one which has provision for both functions. But when holes are of large dimensions the drilling machine is useless because the proportions and gears are unsuitable. A 6-in. drill is unusually large, but holes are bored up to 30 ft. or more in diameter.

Types of Machines.—The distinction between machines with vertical and horizontal spindles is not vital, but of convenience only. The principal controlling element in design is the mass of the work, which often determines whether it or the machine shall be adjusted relatively to each other. Also the dimensions of a hole determine the speed of the tools, and this controls the design of the driving and feeding mechanism. Another important difference is that between drilling or boring one or more holes simultaneously. With few exceptions the tool rotates and the work is stationary. The notable exceptions are the vertical boring lathes already mentioned. Obviously the demands made upon drilling machines are nearly as varied as those on lathes. There is little in common between the machines which are serviceable for the odd jobs done in the general shop and those which are required for the repetitive work of the shops which handle specialities. Provision often has to be made for drilling simultaneously several holes at certain centres or holes at various angles or to definite depths, while the mass of the spindles of the heavier machines renders counter-balancing essential.

Bench Machines are the simplest and smallest of the group. They are operated either by hand or by power. In the power machines generally, except in the smallest, the drill is also fed downwards by power, by means of toothed gears. The upper part of the drilling

E, Drill spindle.
F, Main driving cones driving vertical shaft *G* through mitre-gears *H*.
J, Spur-wheels, driving from *C* to vertical shaft *K*.
L, Mitre-wheels, driving from *K* to horizontal shaft *M*, having its bearings in the radial arm.
N, Nest of mitre-wheels driving the wheel spindle *E* from *M*.
O, Feed-gears to drill spindle, actuated by hand-wheel *P* or worm-gears *Q*.
R, *R*, Feed cones driving from shaft *M* to worm-shaft *S*, for self-acting feed of drill.
T, Change-speed gears.
U, Hand-wheel for racking carriage *D* along radial arm *C*.
V, Clutch and lever for reversing direction of rotation of spindle.
W, Worm-gear for turning pillar *B*.
d, Handle for turning worm.
X, Screw for adjusting the height of the radial arm.
Y, Gears for actuating ditto from shaft *C*.
Z, Rod with handle for operating elevating gear.

spindle being threaded is turned by an encircling spur-wheel, operated very slowly by a pinion and hand-wheel by the right hand of the attendant, the movement being made independent of the rotation of the spindle. A rack sleeve encircling the spindle is also common. In the power machines gears are also used, but a belt on small cone pulleys drives from the main cone shaft at variable speeds. From three to four drilling and feeding speeds are provided for by the respective cone pulleys. Work is held on or bolted to a circular table, which may have provision for vertical adjustment to suit pieces of work of different depths, and which can usually be swung aside out of the way to permit of deep pieces of work being introduced, resting on the floor or on blocking.

Wall Machines.—One group of these machines resembles the bench machines in general design, but they are made to bolt to a wall instead of on a bench. Their value lies in the facilities which they afford for drilling large pieces of work lying on the floor o on blocking, which could not go on the tables of the bench machines. Sometimes a compound work-table is fastened to the floor beneath; and several machines also are ranged in line, by means of which long plates, angles, boilers or castings may be brought under the simultaneous action of the group of machines. Another type is the radial arm machine, with or without a table beneath. In each case an advantage gained is that a supporting pillar or standard is not required, its place being taken by the wall.

Self-contained Pillar Machines include a large number having the above-named feature in common. In the older and less valuable types the framework is rigid, and the driving and feeding are by belt cones. But the machines being mostly of larger capacities than those just noted, back-gears similar to those of lathes are generally introduced. The spindles also are usually counterbalanced. The machine framing is bolted to a bed-plate. A circular work-table may or may not be included. When it is, provision is made for elevating the table by gears, and also for swinging it aside when deep work has to be put on the base-plate.

Radial Arm Machines.—In these (fig. 46) the drilling mechanism is carried on a radial arm which is pivoted to the pillar with the object of moving the drill over the work, when the latter is too massive to permit of convenient adjustment under the drill. The driving takes place through shafts at right angles, from a horizontal shaft carrying the cones and back-geared to a vertical one, thence to a horizontal one along the radial arm, whence the vertical drilling spindle is driven. The latter has its bearings in a carriage which can be traversed along the arm for adjustment of radius. The spindle is counterbalanced. Hand as well as power adjustments are included. In the work-tables of radial and rigid machines there is a great diversity, so that work can be set on top, or at the sides, or at an angle, or on compound tables, so covering all the requirements of practice.

Sensitive Machines have developed greatly and have superseded many of the older, slower designs. The occasion for their use lies in the drilling of small holes, ranging up to about an inch in diameter. They are belt-driven, without back-gears, and usually without bevel-gears to change the direction of motion. The feed is by lever moving a rack sleeve. A slender pillar with a foot supports the entire mechanism, and the work-table, with a range of vertical adjustment.

Multiple Spindle Machines.—Many of the sensitive machines are fitted with two, three or more spindles operated in unison with a belt common to all. In other machines the multiple spindles are capable of adjustment for centres, as in the machines used by boiler makers and platers. In others the spindles are adjustable in circles of varying radii, as in those employed for drilling the bolt holes in pipe flanges. In many of these the spindles are horizontal. Some very special multiple-spindle machines have the spindles at different angles, horizontal and vertical, or at angles.

Universal Machines are a particular form of the pillar type in which the spindle is horizontal, moving with its carriage on a pillar capable of traversing horizontally along a bed; the carriage has vertical adjustment on its pillar and so commands the whole of the face of a large piece of work bolted to a low bed-plate adjacent to the machine. The term "universal" signifies that the machine combines provision for drilling, boring, tapping screws and inserting screw studs, facing and in some cases milling. The power required for boring is obtained by double and treble gears. These machines are used largely in marine engine works, where very massive castings and forgings must be operated on with their faces set vertically.

Boring Machines.—Many machines are classified as suitable for drilling and boring. That simply means that provision is made on a drilling machine for boring holes of moderate size, say up to 8 or 10 in., by double and treble back-gears. But the real boring machine is of a different type. In the horizontal machines a splined bar actuated by suitable gears carries a boring head which holds the cutters, which head is both rotated with, and traversed or fed along the bar. The work to be bored is fixed on a table which has provision for vertical adjustment to suit work of different dimensions. The boring-bar is supported at both ends. In the case of the largest work the boring-bar is preferably set with its axis vertically, and the framing of the machine is arch-like. The bar is carried in a bearing at the crown of the arch and driven and fed there by suitable gears, while the other end of the bar rotates in the table which forms the base of the machine. Some boring machines for small engine cylinders and pump barrels have no bar proper, but a long boring spindle carrying cutters at the further end is supported along its entire length in a long stiff boss projecting from the headstock of the machine—the *snout* machine. The work is bolted on a carriage which slides along a bed similar to a lathe bed. Many of these machines have two bars for boring two cylinders simultaneously.

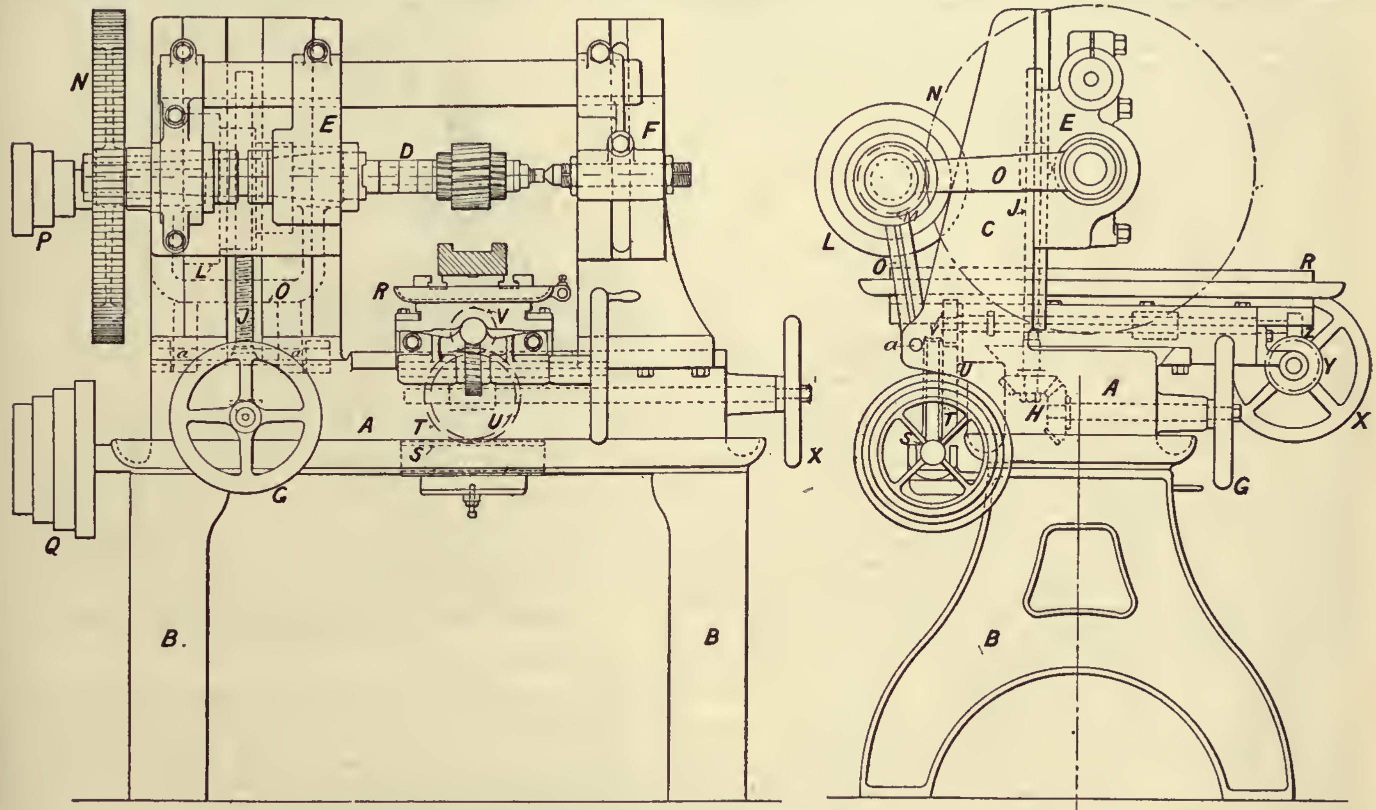

FIG. 47.—Lincoln Milling Machine. (John Holroyd & Co., Ltd., Milnrow.)

A, Bed.
B, *B*, Legs.
C, Upright.
D, Spindle or arbor.
E, Headstock, carrying bearings for spindle *D*.
F, Tailstock, carrying point centre for tail end of spindle.
G, Hand-wheel for effecting adjustment in height of headstock, through bevel-gears *H* and screw *J*.
K, Cross-bar connecting head- and tail-stocks, and ensuring equal vertical adjustment of the spindle bearings from the screw *J*.
L, Speed cones for driving spindle, through pinion *M* and wheel *N*.
O, Frame, carrying the bearings for the cone pulley *L*, and pivoted to the bed at *a*, and to the headstock *E*. This device keeps the gears *M* and *N* in engagement in all variations in the height of the spindle *D*.
P, *Q*, Cones for driving the table *R* through worm-gears *S*, *T*, and spurs *U*, *V*, to the table screw.
W, Stop for automatic knock-off to feed.
X, Hand-wheel for turning the same screw through worm-gears *Y*, *Z*.

IV.—Milling Machines

In milling machines rotary saw-like cutters are employed. To a certain extent these and some gear-cutting machines overlap because they have points in common. Many gear-wheel teeth are produced by rotary cutters on milling machines. In many machines designed for gear cutting only, rotary cutters alone are used. For this reason the two classes of machines are conveniently and naturally grouped together, notwithstanding that a large and increasing group of gear-cutting machines operate with reciprocating tools.

The French engineer, Jacques de Vaucanson (1709–1782), is credited with having made the first milling cutter. The first very crude milling machine was made in 1818 at a gun factory in Connecticut. To-day the practice of milling ranks as of equal economic value with that of any other department of the machine shop, and the varieties of milling machines made are as highly differentiated as are those of any other group. An apparent incongruity which is rather striking is the relative disproportion between the mass of these machines and the small dimensions of the cutters. The failures of many of the early machines were largely due to a lack of appreciation of the intensity of the stresses involved in milling. A single-edged cutting tool has generally a very narrow edge in operation. Milling cutters are as a rule very wide by comparison, and several teeth in deep cuts are often in simultaneous operation. The result is that the machine spindle and the arbor or tool mandrel are subjected to severe stress, the cutter tends to spring away from the surface being cut, and if the framings are of light proportions they vibrate, and inaccuracy and chatter result. Even with the very stiff machines now made it is not possible to produce such accurate results on wide surfaces as with the planer using a narrow-edged tool. Because of this great resistance and stress, cutters of over about an inch in width are always made with the teeth arranged spirally, and wide cutters which are intended for roughing down to compete with the planer always have either inserted cutters or staggered teeth. Hence the rotary cutter type of machine has not been able to displace the planing machine in wide work when great accuracy is essential. Its place lies in other spheres, in some of which its position is unassailable. Nearly all pieces of small and medium dimensions are machined as well by milling as by single-edged tools. All pieces which have more than one face to be operated on are done better in the milling machine than elsewhere. All pieces which have profiled outlines involving combinations of curves and plane faces can generally only be produced economically by milling. Nearly all work that involves equal divisions, or pitchings, as in the manufacture of the cutters themselves, or spiral cutting, or the teeth of gear-wheels when produced by rotary cutters, must be done in milling machines. Beyond these a large quantity of work lies on the border-line, where the choice between milling and planing, shaping, slotting, &c., is a matter for individual judgment and experience. It is a matter for some surprise that round the little milling cutter so many designs of machines have been built, varying from each other in the position of the tool spindles, in their number, and in the means adopted for actuating them and the tables which carry the work.

A very early type of milling machine, which remains extremely popular, was the Lincoln. It was designed, as were all the early machines, for the small arms factories in the United States. The necessity for all the similar parts of pistols and rifles being interchangeable, has had the paramount influence in the development of the milling machine. In the Lincoln machine as now made (fig. 47) the work is attached to a table, or to a vice on the table, which has horizontal and cross traverse movements on a bed, but no capacity for vertical adjustment. The cutter is held and rotated on an arbor driven from a headstock pulley, and supported on a tail-stock centre at the other end, with capacity for a good range of vertical adjustment. This is necessary both to admit pieces of work of different depths or thicknesses between the table and the cutter, and to regulate the depth of cutting (vertical feed). Around this general design numerous machines small and large, with many variations in detail, are built. But the essential feature is the vertical movement of the spindle and cutter, the support of the arbor (cutter spindle) at both ends, and the rigidity afforded by the bed which supports head- and tail-stock and table.

The pillar and knee machines form another group which divides favour about equally with the Lincoln, the design being nearly of an opposite character. The vertical movements for setting and feed are imparted to the work, which in this case is carried on a bracket or knee that slides on the face of the pillar which supports the headstock. Travelling and transverse movements are imparted to the table slides. The cutter arbor may or may not be supported away from the headstock by an arched overhanging arm. None of these machines is of large dimensions. They are made in two leading designs—the plain and the universal. The first embodies rectangular relations only, the second is a marvellous instrument both in its range of movements and fine degree of precision. The first machine of this kind was exhibited at Paris in 1867. The design permits the cutting of spiral grooves, the angle of which is embodied in the adjustment of a swivelling table and of a headstock thereon (universal or spiral head). The latter embodies change-gears like a screw-cutting lathe and worm-gear for turning the head, in combination with an index or dividing plate having several circles of holes, which by the insertion of an index peg permit of the work spindle being locked during a cut. The combinations possible with the division plate and worm-gear number hundreds. The head also has angular adjustments in the vertical direction, so that tapered work can be done as well as parallel. The result is that there is nothing in the range of spiral or parallel milling, or tapered work or spur or bevel-gear cutting, or cutter making, that cannot be done on this type of machine, and the accuracy of the results of equal divisions of pitch and angle of spiral do not depend on the human element, but are embodied in the mechanism.

V, Spiral gears indicated for effecting self-acting rotation of circular table *W*.
X, Hand-wheel for rotation of table.
Y, Hand-wheel for vertical movements of knee *B* on screw *Z*.

Machines with vertical spindles (fig. 48) form another great group, the general construction of which resembles that either of the common drilling machine or of the slotting machine. In many cases the horizontal position is preferable for tooling, in others the vertical, but often the matter is indifferent. For general purposes, the heavier class of work excepted, the vertical is more convenient. But apart from the fitting of a special brace to the lower end of the spindle which carries the cutter, the spindle is unsupported there and is thus liable to spring. But a brace can only be used with a milling cutter that operates by its edges, while one advantage of the vertical spindle machine is that it permits of the use of end or face cutters. One of the greatest advantages incidental to the vertical position of the spindle is that it permits of profile milling being done. One of the most tedious operations in the machine shop is the production of outlines which are not those of the regular geometric figures, as rectangles and circles, or combinations of the same. There is only one way in which irregular forms can be produced cheaply and interchangeably, and that is by controlling the movements of the tool with an object of similar shape termed a "form" or "former," as in the well-known copying lathes, in the cam grinding machine, and in the forming adjuncts fitted to vertical spindle milling machines, so converting those into profiling machines. The principle and its application are alike simple. An object (the form) is made in hardened steel, having the same outlines as the object to be milled, and the slide which carries the cutter spindle has a hardened former pin or roller, which is pulled hard against the edges of the form by a suspended weight, so causing the tool to move and cut in the same path and in the same plane around the edges of the work. Here the milling machine holds a paramount place. No matter how many curves and straight portions may be combined in a piece, the machine reproduces them all faultlessly, and a hundred or a thousand others all precisely alike without any tentative corrections.

Plano-millers, also termed slabbing machines, form a group that grows in value and in mass and capacity. They are a comparatively late development, becoming the chief rivals to the planing machines, for all the early milling was of a very light character. In general outlines the plano-millers closely resemble the planing machines, having bed, table, housings and cross-rail. The latter in the plano-miller carries the bearings for the cutter spindle or spindles under which the work travels and reciprocates. These spindles are vertical, but in some machines horizontal ones are fitted also, as in planers, so that three faces at right or other angles can be operated on simultaneously. The slabbing operations of the plano-millers do not indicate the full or even the principal utilities of these machines. To understand these it must be remembered that the cross-sections of very many parts which have to be tooled do not lie in single planes merely, but in combinations of plane surfaces, horizontal, vertical or angular. In working these on the planing machine separate settings of tools are required, and often successive settings. But milling cutters are built up in "gangs" to deal with such cases, and in this way the entire width of profile is milled at once. Horizontal faces, and vertical and angular edges and grooves, are tooled simultaneously, with much economy in time, and the cutter profile will be accurately reproduced on numbers of separate pieces. Allied to the plano-millers are the rotary planers. They derive their name from the design of the cutters. An iron disk is pierced with holes for the insertion of a large number of separate cutters, which by the rotation of the disk produce plane surfaces. These are milling cutters, though the tools are single-edged ones, hence termed "inserted tooth mills." These are used on other machines besides the rotary planers, but the latter are massive machines built on the planer model, with but one housing or upright to carry the carriage of the cutter spindle. These machines, varied considerably in design, do good service on a class of work in which a very high degree of accuracy is not essential, as column flanges, ends of girders, feet of castings, and such like.

V.—Gear-cutting Machines

The practice of cutting the teeth of gear-wheels has grown but slowly. In the gears used by engineers, those of large dimensions are numerous, and the cost of cutting these is often prohibitive, though it is unnecessary in numbers of mechanisms for which cast wheels are as suitable as the more accurately cut ones. The smallest gears for machines of precision have long been produced by cutting, but of late years the practice has been extending to include those of medium and large dimensions, a movement which has been largely favoured by the growth of electric driving, the high speeds of which make great demands on reduction and transmission gears. Several new types of gear-cutting machines have been designed, and specialization is still growing, until the older machines, which would, after a fashion, cut all forms of gears, are being ousted from modern establishments.

The teeth of gear-wheels are produced either by rotary milling cutters or by single-edged tools (fig. 49). The advantage of the first is that the cutter used has the same sectional form as the intertooth space, so that the act of tooth cutting imparts the shapes without assistance from external mechanism. But this holds good only in regard to spur-wheel teeth, that is, those in which the teeth lie parallel with the axis of the wheel. The teeth of bevel-wheels, though often produced by rotary cutters, can never be formed absolutely correctly, simply because a cutter of unalterable section is employed to form the shapes which are constantly changing in dimensions along the length of the teeth (the bevel-wheel being a frustum of a cone). Hence, though fair working teeth are obtained in this way, they result from the practice of varying the relative angles of the cutters and wheel and removing the material in several successive operations or traverses, often followed by a little correction with the file. Although this practice is still commonly followed in bevel-wheels of small dimensions, and was at one time the only method available, the practice has been changing in favour of shaping the teeth by a process of planing with a single-edged reciprocating tool. As, however, such a tool embodies no formative section as do the milling cutters, either it or the wheel blank, or both, have to be coerced and controlled by mechanism outside the tool itself. Around this method a number of very ingenious machines have been designed, which may be broadly classed under two great groups—the form and the generating types.

In the form machines a pattern tooth or form-tooth is prepared in hardened steel, usually three times as large as the actual teeth to be cut, and the movement of the mechanism which carries the wheel blank is coerced by this form, so that the tool, reciprocated by its bar, produces the same shape on the reduced dimensions of the wheel teeth. The generating machines use no pattern tooth, but the principles of the tooth formation are embodied in the mechanism itself. These are very interesting designs, because they not only shape the teeth without a pattern tooth, but their movements are automatically controlled. A large number of these have been brought out in recent years, their growth being due to the demand for accurate gears for motor cars, for electric driving, and for general high-class engineers' work. These are so specialized that they can only cut the one class of gear for which they are designed—the bevel-wheels, and these in only a moderate range of dimensions on a single machine of a given size. The principal bevel-gear cutting machines using forms or formers, are the Greenwood & Batley, Le Progrès Industriel, the Bouhey (cuts helical teeth), the Oerlikon, which includes two types, the single and double cutting tools, the Gleason and the Rice. Generating machines include the Bilgram (the oldest), the Robey-Smith, the Monneret, the Warren, the Beale and the Dubosc.

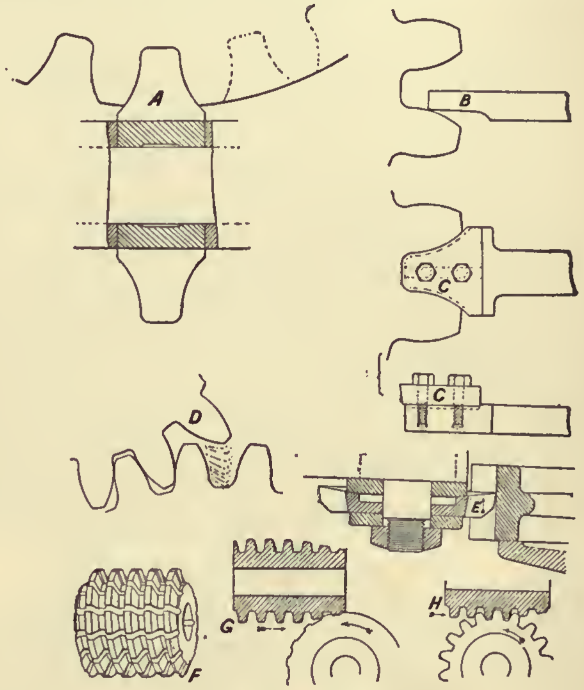

Fig. 49.—Gear Cutting.

A, Rotary milling cutter producing tooth space.
B, Planer tool operating on tooth flank.
C, Planer form-tool finishing tooth space.
D, Action of "Fellows" cutter, planing teeth.
E, Shape of "Fellows" cutter.
F, Hobbing cutter.
G, Tapered hob beginning worm-wheel.
H, Ditto finishing.

As the difficulties of cutting bevel-wheels with rotary cutters, consequent on change of section of the teeth, do not occur in spur-gears, there are no examples of form machines for spur-wheel cutting, and only one generating planing type of machine, the Fellows, which produces involute teeth by a hardened steel-cutting pinion, which shapes wheels having any number of teeth of the same pitch, the cutter and blank being partly rotated between each cut as they roll when in engagement.

The worm-gears appropriate a different group of machines, the demands on which have become more exacting since the growth of electric driving has brought these gears into a position of greater importance than they ever occupied before. With this growth the demand for nothing less than perfect gears has developed. A perfect gear is one in which the teeth of the worm-wheel are envelopes of the worm or screw, and this form can only be produced in practice in one way—by using a cutter that is practically a serrated worm (a hob), which cuts its way into the wheel just as an actual worm might be supposed to mould the teeth of a wheel made of a plastic substance. To accomplish this the relative movements of the hob and the wheel blank are arranged to be precisely those of the working worm and wheel. Very few such machines are made. A practical compromise is effected by causing the hob both to drive and cut the blank in an ordinary machine. When worms are not produced by these methods the envelope cannot be obtained, but each tooth space is cut by an involute milling cutter set at the angle of thread in a universal machine, or else in one of the general gear-cutting machines used for spur, bevel and worm gears, and only capable of yielding really accurate results in the case of spur-wheels.

The previous remarks relate only to the sectional forms of the teeth. But their pitch or distance from centre to centre requires dividing mechanism. This includes a main dividing or worm-wheel, a worm in conjunction with change gears, and a division plate for setting and locking the mechanism. The plate may have four divisions only to receive the locking lever or it may be drilled with a large number of holes in circles for an index peg. The first is adopted in the regular gear-cutters, the second on the universal milling machines which are used also for gear-cutting. In the largest number of machines this pitching has to be done by an attendant as often as one tooth is completed. But in a good number of recent machines the pitching is effected by the movements of the machine itself without human intervention. With spur-wheels the cutting proceeds until the wheel is complete, when the machine is often made to ring a bell to call attention to the fact. But in bevel-wheels only one side of the teeth all the way round can be done; the attendant must then effect the necessary settings for the other side, after which the pitchings are automatic.

As a general rule only one tooth is being operated on at one time. But economy is studied in spur-gears by setting several similar wheels in line on a mandrel and cutting through a single tooth of the series at one traverse of the tool. In toothed racks the same device is adopted. Again, there are cases in which cutters are made to operate simultaneously on two, three or more adjacent teeth.

Recently a generating machine of novel design has been manufactured, the spur-wheel hobbing machine. In appearance the hob resembles that employed for cutting worm-gears, but it also generates the teeth of spur and spiral gears. The hob is a worm cut to form teeth, backed off and hardened. The section of the worm thread is that of a rack. Though it will cut worm-wheels, spiral-wheels or spur-wheels equally correctly, the method of presentation varies. When cutting worm-wheels it is fed inwards perpendicularly to the blank; when cutting spirals it is set at a suitable angle and fed across the face of the blank. The angle of the worm thread in the hob being about $2\frac{1}{2}°$, it has to be set by that amount out of parallel with the plane of the gear to be cut. It is then fed down the face of the wheel blank, which is rotated so as to synchronize with the rotation of the worm. This is effected through change gears, which are altered for wheels having different numbers of teeth. The advantage is that of the hob over single cutters; one hob serves for all wheels of the same pitch, and each wheel is cut absolutely correct. While using a set of single cutters many wheels must have their teeth only approximately correct.

VI.—Grinding Machines

The practice of finishing metallic surfaces by grinding, though very old, is nevertheless with regard to its rivalry with the work of the ordinary machine tools a development of the last part of the 19th century. From being a non-precision method, grinding has become the most perfect device for producing accurate results measured precisely within thousandths of an inch. It would be rather difficult to mention any class of machine-shop work which is not now done by the grinding wheel. The most recent developments are grinding out engine cylinders and grinding the lips of twist drills by automatic movements, the drills rotating constantly.

There are five very broad divisions under which grinding machines may be classified, but the individual, well-defined groups or types might number a hundred. The main divisions are: (1) Machines for dealing with plane surfaces; (2) machines for plain cylindrical work, external and internal; (3) the universals, which embody movements rendering them capable of angular setting; (4) the tool grinders; and (5) the specialized machines. Most of these might be again classed under two heads, the non-precision and the precision types. The difference between these two classes is that the first does not embody provision for measuring the amount of material removed, while the second does. This distinction is a most important one.

The underlying resemblances and the differences in the main designs of the groups of machines just now noted will be better understood if the essential conditions of grinding as a corrective process are grasped. The cardinal point is that accurate results are produced by wheels that are themselves being abraded constantly. That is not the case in steel cutting tools, or at least in but an infinitesimal degree. A steel tool will retain its edge for several hours (often for days) without the need for regrinding, but the particles of abrasive in an emery or other grinding wheel are being incessantly torn out and removed. A wheel in traversing along a shaft say of 3 ft. in length is smaller in diameter at the termination than at the beginning of the traverse, and therefore the shaft must be theoretically larger at one end than the other. Shafts, nevertheless, are ground parallel. The explanation is, and it lies at the basis of emery grinding, that the feed or amount removed at a single traverse is extremely minute, say a thousandth or half a thousandth of an inch. The minuteness of the feed receives compensation in the repetition and rapidity of the traverse. The wear of the wheel is reduced to a minimum and true work is produced.

From this fact of the wear of grinding wheels two important results follow. One is that a traverse or lateral movement must always take place between the wheel and the piece of work being ground. This is necessary in order to prevent a mutual grooving action between the wheel and work. The other is that it is essential to provide a large range in quality of wheels, graded according to coarseness and fineness, of hardness and softness of emery to suit all the different metals and alloys. Actually about sixty grades are manufactured, but about a dozen will generally cover average shop practice. With such a choice of wheels the softest brass as well as the hardest tempered steel or case-hardened glass-like surfaces that could not possibly be cut in lathe or planer, can be ground with extreme accuracy.

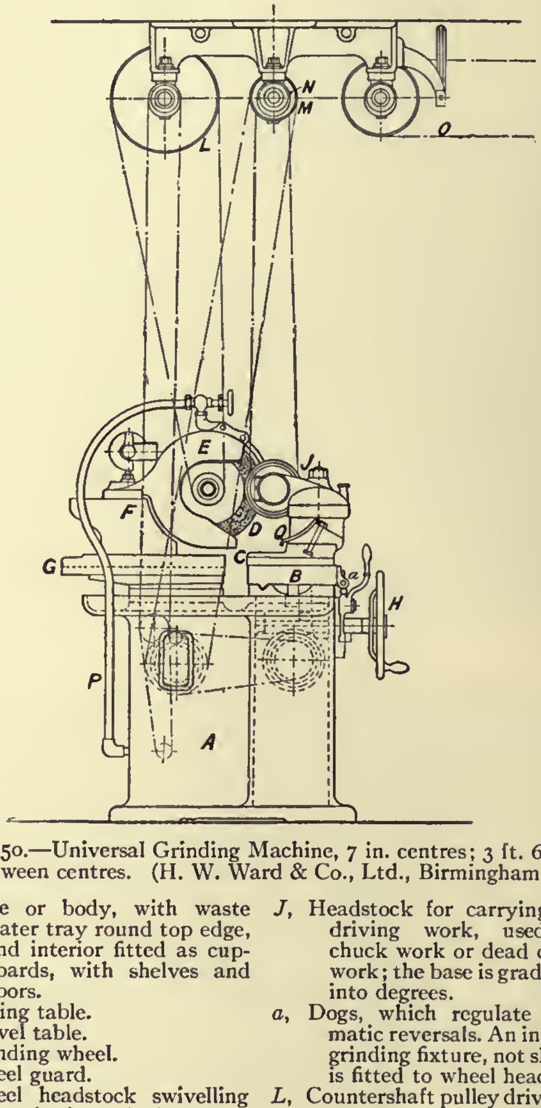

Fig. 50.—Universal Grinding Machine, 7 in. centres; 3 ft. 6 in. between centres. (H. W. Ward & Co., Ltd., Birmingham.)

M, Pulley driving to cones.
N, Pulley driving to work headstock pulley.
O, Belt from line shaft.
P, Water pipe from pump.
Q, Water guards above table.

Plane surfacing machines in many cases resemble in general outlines the well-known planing machine and the vertical boring mill. The wheels traverse across the work, and they are fed vertically to precise fractional dimensions. They fill a large place in finishing plane surfaces, broad and narrow alike, and have become rivals to the planing and milling machines doing a similar class of work. For hardened surfaces they have no rival.

Cylindrical grinders include many subdivisions to embrace external and internal surfaces, either parallel or tapered, small or large. In their highest development they fulfil what are termed "universal" functions (fig. 50), that is, they are capable of grinding both external and internal cylinders, plane faces, tapers, both of low and high angle, and the teeth of various kinds of tools and cutters. These machines occur in two broad types. In one the axis of the revolving wheel is traversed past the work, which revolves but is not traversed. In the other the reverse occurs, the work traversing and the axis of the wheel with its bearings remaining stationary. Equally satisfactory results are obtained by each.

In all external cylindrical grinding, when the work can be rotated, the piece being ground rotates in an opposite direction to the rotation of the wheel (fig. 51, *A*). In all small pieces ground internally the same procedure is adopted (fig. 51, *B*). Incidentally,

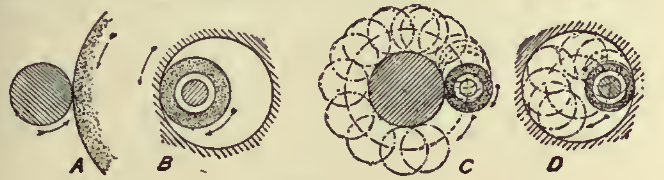

FIG. 51.

A, External cylindrical grinding. *B*, Internal ditto. *C*, External grinding when the work is fixed. *D*, Internal ditto.

mention should be made of the fineness of the fitting required and attained in the construction of the spindles which carry the wheels for internal grinding. The perfection of fitting and of the means of adjustment for eliminating the effects of wear in the ordinary spindles for external and internal grinding is remarkable. The spindles for internal work have to revolve at rates ranging from about 6000 to 30,000 times in a minute, yet run so truly that the holes ground do not depart from accuracy by more than say $\frac{1}{5000}$ to $\frac{1}{10000}$ of an inch. Yet so long as the work can be revolved no special complication of mechanism is required to ensure good results. The revolution of the wheel and the work is mutually helpful. The real difficulties arise when the work, on account of its mass or awkwardness of shape, cannot be revolved. The principle embodied in machines designed to deal satisfactorily with such cases, though much diversified in detail, is the application of the planet device to the grinding wheels. That is, the wheel spindle rotating at a high speed, 6000 or 7000 revolutions per minute, is simultaneously carried round in a circular path, so that its axis makes about 25 or 30 revolutions per minute (fig. 51, *C* and *D*). The diameter of the path is capable of adjustment with minute precision within wide limits to suit bores of different diameters. The periphery of the grinding wheel which lies farthest from its axis of revolution sweeps round in a path the diameter of which equals that of the bore to be ground. These machines are now used largely for grinding out the cylinders of gas and petrol engines, valve seatings, the bushed holes of coupling rods, and similar classes of work. Many of them have their spindles set horizontally, others vertically.

Allied to these are a relatively small but important group of machines used for grinding the slot links of the slide-valve gear of locomotive and other engines. The slot is mounted on a pivoted bar adjusted to the same radius as the slot to be ground, and the slot is moved relatively to the wheel, so producing the required curves.

In another direction much development has taken place in the practice of grinding. The increasing use of the milling cutter has

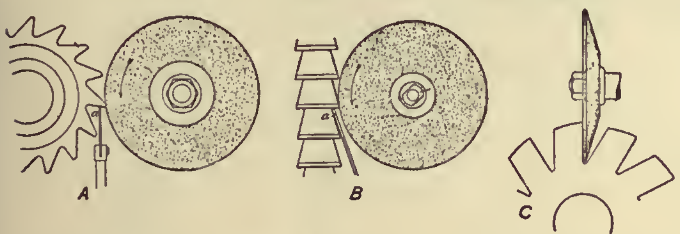

FIG. 52.

A, Grinding front edges of milling cutter. *B*, Grinding side edges of milling cutter; *a*, *a*, Tooth rests. *C*, Grinding face of formed mill.

been the occasion for the growth and high specialization of the cutter grinding machines. It is essential to the efficiency of such cutters that regrinding shall be done without drawing the temper, and this can only be effected by the use of an abrasive. In the early days of their use the temper had to be drawn to permit of filing and rehardening effected with its inevitable distortion.

Cutter grinding machines must possess universality of movements to deal with the numerous shapes in which milling cutters are made; hence they often resemble in general outlines the universal grinding machines. But as a rule they are built on lighter models, and with a smaller range of movements, because the dimensions of cutters are generally much smaller than those of the ordinary run of engineers' work which has to be ground. Frequently a single pillar or standard suffices to carry the mechanism. In an ordinary universal tool grinder all the teeth of any form of cutter can be ground precisely alike (fig. 52) excepting those having irregular profiled outlines, for which a special machine, or an extra attachment to an ordinary machine, is necessary. But little of this is done, because in such cases, and in many others, the faces of the teeth are ground instead of the edge. This idea, due to the firm of Brown & Sharpe, may seem a trifle, but nevertheless to it the credit is largely due for the economies of cutter grinding. The principle is that in the "formed cutter," as it is termed, the profiles of the teeth are not struck from the axis of revolution, but from another centre (fig. 20); grinding the tooth faces, therefore, has no effect on the shapes of the profiles, but only lessens the tooth thicknesses. Designed originally for the cutters for the teeth of gear-wheels, it has long been applied to profiles which involve combinations of curves. The pitching of the teeth is effected by a strip of metal, or tooth rest *a* (fig. 52), on which each successive tooth rests and is coerced during the grinding. If teeth are of special form the traverse movement of a spiral tooth along the rest ensures the required movement.

Besides the cutter grinders used for milling cutters, reamers and screwing taps, there are two other groups of tool grinders, one for twist drills only and the other for the single-edged tools used in lathe, planer, shaper and other machines. Both these in their best forms are of recent development. The machines used for grinding twist drills embody numerous designs. Hand grinding is practically abandoned, the reason being that a very minute departure from symmetry on the two cutting lips of the drill results inevitably in the production of inaccurate holes. It is essential that the two lips be alike in regard to length, angle and clearance, and these are embodied in the mechanism of the grinding machines. But formerly in all these the drill holder had to be moved by hand around its pivot, and one lip ground at a time There are now some very beautiful machines of German manufacture in which the necessary movements are all automatic, derived from the continuous rotation of a belt pulley. The drill rotates constantly, and small amounts are ground off each lip in turn until the grinding is finished. The other group for grinding single-edged tools is a very small one. The correct angles for grinding are embodied in the setting of the machine, with the great advantage that any number of similar tools can be ground all alike without skilled attendance.

Lying outside these broad types of machines there is a large and growing number designed for special service. The knife-grinding group for sharpening the planer knives used in wood-working machinery is a large one. Another is that for gulleting or deepening the teeth of circular saws as they wear. Another is designed for grinding the cups and cones for the ball races of cycle wheels, and another for grinding the hardened steel balls employed in ball bearings.

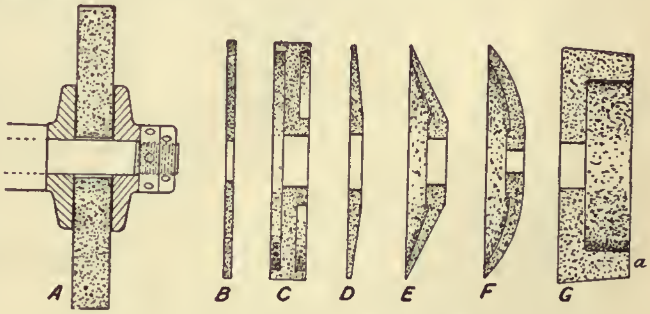

FIG. 53.—Typical Grinding Wheels.

A, Common disk held on spindle with washers and nuts.
B, Thin disk.
C, Flanged disk for grinding to shoulders.
D, Bevelled disk for cutter grinding.
E, *F*, Cupped and dished wheels for cutter grinding.
G, Cup wheel for grinding on face *a*; diameter remains constant.

Emery grinding is dependent for much of its success on a plentiful supply of water. Dry grinding, which was the original practice, is hardly employed now. The early difficulties of wet grinding were due to the want of a cementing material which would not soften under the action of water. Now wheels will run constantly without damage by water, and they are so porous that water will filter through them. Improvements in the manufacture of wheels, and the increased use of water, have concurred to render possible heavier and more rapid grinding without risk of distortion due to heating effects. In the best modern machines the provisions for water supply are a study in themselves, including a centrifugal pump, a tank, jointed piping, spraying tube, guards to protect the bearings and slides from damage, and trays to receive the waste water and conduct it back to the tank.

There are two points of view from which the modern practice of grinding is now regarded—one as a corrective, the other as a formative process. The first is the older and is still by far the most important. The second is a later ideal towards which design and practice have been extending. As yet grinding cannot compete with the work of the single-edged tools and milling cutters when large quantities of material have to be removed. Just as some leading firms have been designing stiffer machines having fuller lubrication with a view to increase the duty of grinding wheels, the advent of the high-speed steels has given a new lease of life to the single-edged cutting tools. The rivalry now lies not with the tools of carbon temper steel, but with high-speed varieties. But as a corrective process grinding never occupied so important a position as it does to-day, and its utility continues to extend.

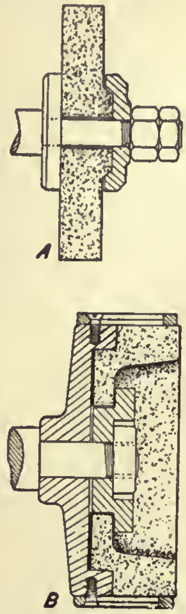

FIG. 54.—Safety Devices.
A, Grinding wheel, with coned washer to retain broken pieces in case of fracture.
B, Cup wheel with encircling ring, moved backwards as the wheel face wears.

The commoner forms in which grinding wheels are made are shown in fig. 53. These are varied largely in dimensions, from tiny cylindrical rollers a fraction of an inch in diameter for hole grinding, to big wheels of 3 ft. or more in diameter. Safety mountings, two examples of which are shown in fig. 54, embody means of retaining the broken pieces of a wheel in case it bursts.

Sand-blast.—The well-known erosive action of sand when driven against rocks and stones by the wind is utilized industrially in the sand-blast apparatus, the invention of B. C. Tilghman. The sand is propelled by a current of steam or air, and being delivered through a nozzle is directed against the surface of the work, cutting it away by the action of the enormous number of grains striking the face, each removing a very minute quantity of material. The action is very gentle, and may be modified by varying the class of sand and its velocity. Other materials, such as emery, chilled iron globules, &c., are employed for certain classes of work. In some instances the powder is used dry, in others it is mixed with water, being then in the condition of fluid mud. The plant includes an air-compressing engine, an air reservoir and the blast nozzle through which the air passes and propels the sand in the form of a jet. The pressures range from 8 lb up to about 60 lb per sq. in., depending on the class of work which is done.

The peculiar advantage of the sandblast lies in its adaptability to the working of irregular surfaces, which could not be touched by any other class of grinding. The blast penetrates hollows and recesses, and acts over an entire surface. There are many classes of operation done with the sand-blast, including cleaning, frosting, ornamentation, engraving and sharpening. In engineers' works a large amount of cleaning is effected upon castings, forgings, sheets and other products, either preparatory to machining or to painting, enamelling, tinning, galvanizing or plating. Cycle frames are cleaned with the sand-blast after brazing. The teeth of files are sharpened by directing a stream of sand and water against their backs, with the result that the burr thrown up by the chisel when cutting is obliterated, and a strong form of tooth is produced. Worn files may also be sharpened up to equal new ones by sand-blasting them. Frosting glass is another useful application of the sand-blast, and by attaching suitable patterns or designs to the surface the sand may be caused to work ornamental figurings. It is a peculiar circumstance that the sand has little effect upon soft and yielding substances in comparison with the abrasion it produces on hard surfaces, so that the pattern will remain undamaged, while the glass or other object beneath is frosted where the sand reaches it, through the openings. Not only can designs be worked on glass, or cut in stone, but perforations may be made in glass, &c., by the continued action of the sand, without any risk of fracture occurring. Much sand-blasting is performed inside closed chambers, having panes through which the workman watches the progress of the operation. But when the blast must be used in the open, protection is necessary and is afforded to the operator by a special helmet, which keeps out the flying dust and gives a supply of pure air through a tube in a similar fashion to the diver's helmet.

VII.—SAWING MACHINES

Metal-sawing machines are employed extensively in engineering works for cutting off bars, shafts, rails, girders and risers on steel castings, and for getting out curved pieces which would be difficult and expensive to slot. There are three classes of these saws, circular, band and reciprocating. The first named are used for straightforward work, operating at right or other angles, the second for straight cuts and also for curves which cannot be treated with circular saws, and the third for small pieces. The circular saws embody a stiff spindle, carrying the saw disk and driven by gearing. This spindle may be mounted in a sliding bearing to carry it past the work held on a fixed table, or the spindle may be stationary and the work be moved along past the saw. The method of feeding should be sensitive, so that it will "give" and prevent damage

U, H-Girder being sawn off.

to the teeth, should undue stress come upon the saw. This is usually effected by the use of weights or springs, which allow a certain freedom or latitude to the driving gears. The work is held by screw clamps, V-blocks being required in the case of circular objects. A number of pieces, such as shafts, rails or girders, can be fastened down close together in a pile and cut through in one operation.

There is a very useful class of circular saw, the flush-side (fig. 55), that is valuable for cutting close up to a surface. The disk is bolted to a flange on the end of the spindle with countersunk bolts, so that the face is quite flat. Another class of saw used for dealing with girders and bars is carried in bearings upon a pivoted arm, which is pulled downwards by a weight to give the feed. The work is bolted to a table below the saw. Ample lubrication, by oil or soapy water, is essential in cutting wrought iron and steel; it is pumped on the blade, keeping it cool and washing away the cuttings.

Band-saw machines resemble in outline the familiar types employed for sawing wood, but they are necessarily stronger and stiffer, and the saws run at a much lower speed. The tables, moreover, differ in possessing compound slides for moving the work and in the provision of a series of slots on the top table, whereby the object to be sawn is secured with bolts and clamps. The tables are moved automatically or by hand. The rate of cutting must be varied according to the thickness of metal. Lubrication is effected by running the lower saw pulley in a bath of oil or soapy water, which is carried up, so keeping the blade cool and "easing" the cut.

The reciprocating class of saw has until recently been confined to small types for workshop use, termed hack saws, which have a small blade ranging from 12 to 18 in. long. This is strained between a couple of bearings in a frame which is reciprocated above the work clamped in a vice. An arrangement of weights feeds the saw downwards. The larger hack saws cut off bars and girders up to 12 in. across, and in some there is a provision introduced for giving intermittent rotation to the bar, thus presenting fresh faces to the saw. The hack saw is of great utility for comparatively light work, and, as the smallest blades are cheap enough to be thrown away when worn out, there is no trouble and expense connected with their sharpening, as in the circular and band saws. An adaptation of the reciprocating saw is that of the jig type, which has a small blade set vertically and passing up through a table on which the work is laid. It is handy for cutting out dies and various curved outlines, in the same manner that fret-sawing in wood is done.

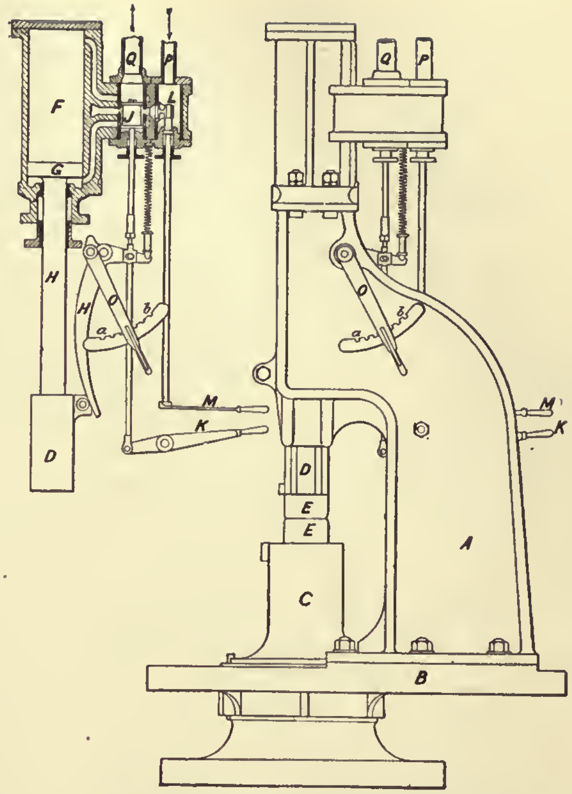

FIG. 57.—Steam Hammer, small Overhanging Type. (B. & S. Massey, Manchester).

A, Standard. *B*, Base-plate.

D, Tup or hammer head.
E, *E*, Pallets, or forging blocks, attached to anvil and tup.
F, Steam cylinder.
G, Piston, solid with piston rod *H*.
J, Piston valve, regulating period of admission of steam, operated by hand by lever *K* or lever *N*.
L, Stop or throttle valve for controlling admission of steam to valve chest, operated by hand lever *M*.
N, Lever in contact with roller on tup *D*, which moves the valve *J* automatically as the tup rises and falls.
O, Lever for pre-adjusting the range of movement of *N* and *J*, according to its setting in the notches of the quadrant from *a* to *b*.
P, Steam supply pipe from boiler. *Q*, Exhaust steam pipe.

VIII.—Shearing and Punching Machines

These have much in common as regards their mode of operation. They are actuated either by belt and spur gearing, by steam-engine, by electric motor, or hydraulically. The first named is only suitable where arrangements can be made for driving from a line shaft. In view of the great convenience of the other methods of driving, they are coming into greater use, especially for ship-yards and other works where shafting is undesirable or inconvenient.

For boiler makers' and platers' use the function of punching, and shearing are usually combined in one machine, the rams being placed at opposite ends and actuated from the same source of power. The last shaft in the train of gearing is set to bring its ends within the boxes containing the rams, and eccentrics on the shaft are moved within die blocks fitted to the rams, so that as the shaft revolves it causes the rams to move up and down and operate the shear blade and the punch attached to the bottom end. Another class of machines is worked by means of massive levers, pivoted in the framing, and actuated by cams on the driving shaft which cause the levers to rock and move the punches or shears up and down by the opposite ends. The punch slides are constructed to "dwell" for a short period at the top of the stroke at each revolution, thus giving the attendant time to place and adjust the plate accurately beneath the punch. The same effect is obtained in the eccentric types of machines mentioned above, by a disengaging motion, which is thrown in by touching a lever, thus stopping the punch until the operator is ready for its descent. The more complete machines have an angle shear situated centrally, with V-blades for severing angle iron. The largest forms of shears, for massive plates, usually have the blade reciprocated by crank or eccentrics on the driving shaft, coupled by connecting-rods to the slide.

Hydraulic punching and shearing machines are used largely on account of their convenience, since they dispense with all belts, engines or motors in the vicinity, and give a very powerful

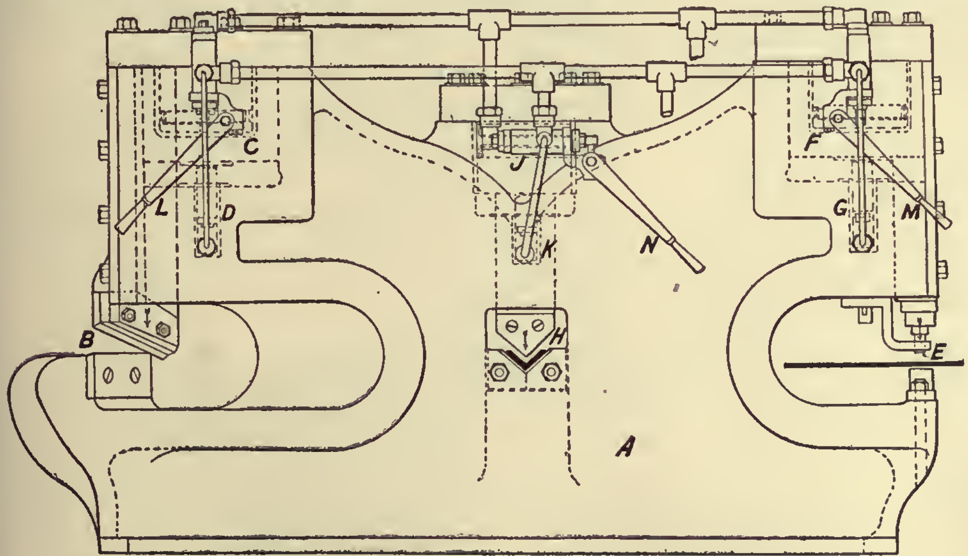

FIG. 56.—Hydraulic Punching and Shearing Machine. (Musgrave Brothers, Leeds.)

stroke. The hydraulic cylinder is generally direct-connected to the slides, and the operator turns on the pressure water by a lever. The machine shown in fig. 56 is a very complete example of the hydraulic type, combining punching and shearing with angle-cutting.

Circular shears are used for the thinner plates and for sheet-metal work; they embody two circular blades placed with their axes parallel, and the sharp bevelled edges nearly in contact. The blades being rotated sever the plate as it is fed between them. Either straight or circular cuts may be made; true circles or disks are produced by mounting the plate on a fixed stud and rotating it through a complete revolution past the cutters.

IX.—Hammers and Presses

The growth in the use of hammers actuated by steam and compressed air, and of presses worked by water power, has been remarkable. The precursors of the power hammers were the helve and the Oliver; the first named was operated by gravity, being lifted by a circle of cams, while the second was lifted by a spring pole overhead and pulled down by the foot of the workman, acting on a lever—the hammer shaft. The first was used by the ironworkers and the second by the smiths, until displaced by the Nasmyth hammer and its extensive progeny. Even now the old helve and Oliver survive in some unprogressive shops.

Steam Hammers.—The original hammer as invented by James Nasmyth was single acting, operating simply by gravity, the function of the steam being to lift the hammer for each succeeding fall. The first improvement was made by Rigby, who took the waste steam exhausted from the lower side of the piston to the upper side and so imparted some slight pressure in the descent. It was a stage between the early and the present hammers. In these, high-pressure steam is admitted above the piston to impart a more powerful blow, compounded of velocity×mass, than is obtainable by gravity; hence they are termed double-acting hammers (fig. 57). The principal difficulties which have to be surmounted in their construction are those due to the severe concussion of the blows, which very sensibly shake the ground over an area of many yards. Framings are made very rigid, and in the larger hammers double, enclosing the hammer head between them. The foundations are by far the heaviest used in any machine tools. Deep piling is often resorted to, supporting crossing timber balks; or concrete is laid in mass on which the iron anvil block is bedded. This block weighs anywhere between 100 and 1000 tons. The piston and its rod and the hammer head are generally a solid steel forging, for the piston rod is a weak element and cottered or screwed fittings are not trustworthy. Piston valves are generally used in preference to ordinary D-valves, combining simplicity of fitting with good balance. The periods of steam admission are under the control of the attendant, so that the length of stroke and the force of the blow are instantly responsive to his manipulation of the operating lever. Many hammers can be set to run automatically for any given length of stroke.

Pneumatic Hammers.—A successful type of hammer for the ordinary operations of the smithy is that which is actuated by compressed air. Though designs vary the principle is the same, namely, air compressed in a controlling cylinder (fig. 58), and brought into an operating or *hammer* cylinder above the piston. Cushioning, or release of the air below the piston, is under control, as is the pressure of the air above it.

Drop Hammers.—The requirements of forged work have, besides the power hammers operated by a positive down stroke, been the cause of the development of an equally large group which are gravity hammers only—the drop hammers. They are put into operation by a belt or belts, but the function of the belt is simply to lift the hammer to the height desired, at which point it is released and falls. The place of the drop hammer is in the lighter class of smith's work, as that of the steam hammer lies in the heavier, but there is much overlapping, since small steam hammers are rivals to the others in light forging.

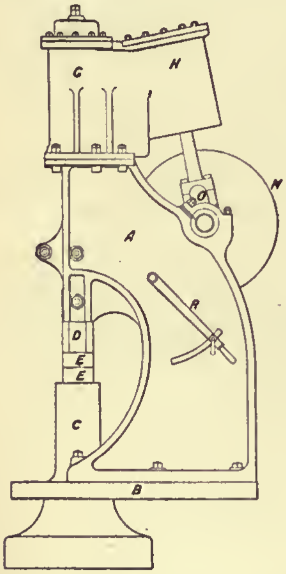

Fig. 58.—Pneumatic Forging Hammer.
(W. & J. Player, Birmingham.)

H, Air compressing cylinder.
N, Belt pulleys which reciprocate by means of the crank *O*, the piston in *H*.
R, Handle controlling the valve between *H* and *G*.

But, speaking generally, the largest volume of repetitive die forging or stamping of light articles is done under drop hammers. The small arms factories and the regular stamping shops scarcely use any other type. They may be roughly divided into three great groups; the belt, the board and the latest form—the Brett lifter. In each the hammer head or tup is lifted to any height within the range of lift, the height being controlled by the attendant at each blow. In most machines setting can be done at any constant height and the blows delivered automatically. Control is effected by hand or foot or both. Drop hammers generally have the advantage of working with greater rapidity than steam hammers.

The original drop hammers, which are believed to have originated with the locksmiths of Birmingham and district, consisted of a hammer head attached to a rope, one end of which ran up over a loose pulley suspended in the roof, and the other was pulled by a man or two men, so lifting the hammer, which was then allowed to drop. The principle is embodied in many belt hammers to-day, but the pulley is driven constantly by shafting, and when the attendant pulls at the free end of the belt the friction of the pulley draws the belt over and lifts the hammer until the attendant lets it go. The weight lifted is greater than in the old type, but the labour is nevertheless very severe, and the blows are not rapid enough for quick forging. A far better machine is the board hammer. In this (fig. 59) the place of the belt is taken by an ordinary strip of board which passes between two rollers at the top of the hammer, which rollers are belt driven. The rollers are fitted on eccentric

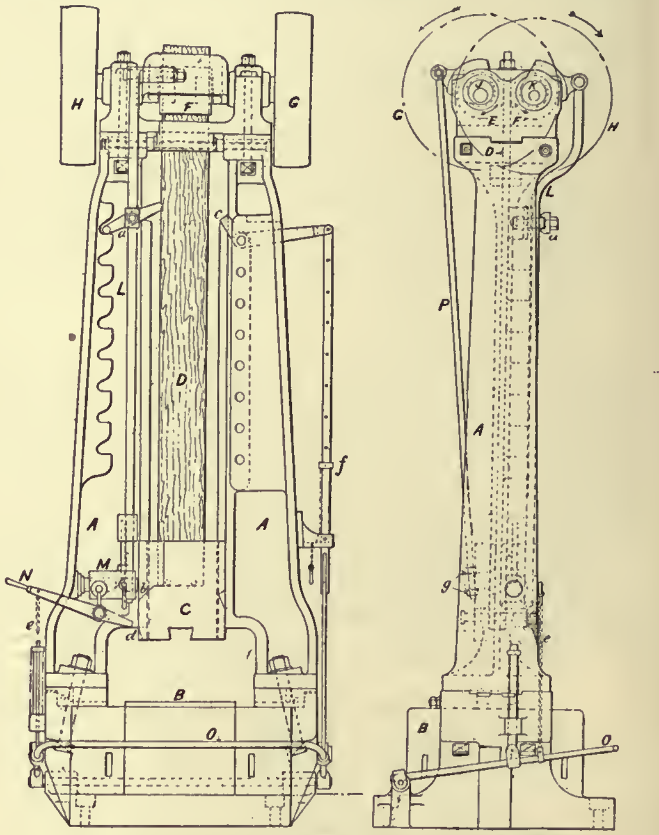

Fig. 59.—Drop Hammer—board type. (B. & S. Massey, Manchester.)

A, *A*, Standards.
B, Anvil, or baseblock.
C, Tup.
D, Board, fitting in slot in tup.
E, *F*, Rollers gripping and lifting board.
G, *H*, Pulleys actuating rollers through eccentrics *J*, *K*.
L, Rod by which the amount of lift is regulated.
a, Dog and lever adjustable on *L*, which strikes the edge *b* of the tup, releasing eccentrics and roller and allowing tup to fall.
c, Catch on which tup rests previous to release, fitted into either one of the row of holes beneath, to suit various heights of drop.
M, Mechanism struck by the edge *d* of the tup, which either keeps the roller *F* clear of the board *D*, allowing the tup to fall, or brings the rollers *E* and *F* into contact, and lifts the board and tup.
N, Hand-lever for operating hammer.
O, Foot-lever for ditto, connected by chain *e*.
f, Spring for lifting levers.
P, Rod with nuts *g*, to compensate for wear on the rollers by the adjustment of roller *E*.

pins, so that the movement of levers causes them to grip the board for the lift, or release it for the fall, these levers being under the control of the attendant. They can also be set to operate automically for any height of lift.

These types are all subject to much concussion and vibration, because the machines are self-contained; anvil, standards and heads being rigidly bolted together, the concussion of every blow is transmitted through the entire mechanism. The Brett hammers (fig. 60) are designed to lessen this, in some cases by making the anvil distinct from the superstructure, and in all by connecting the lifting ropes to the ends of long levers which act something like elastic springs, absorbing vibration. The driving mechanism is also original, comprising a cylinder with a wing piston, which is rotated by steam pressure through an arc of a circle only, sufficiently to operate the lifting levers. Another advantage is that the lifter cylinder need not be immediately over the hammer, but may be situated elsewhere. The hammer can be operated by hand directly for each stroke, or be set to work automatically.

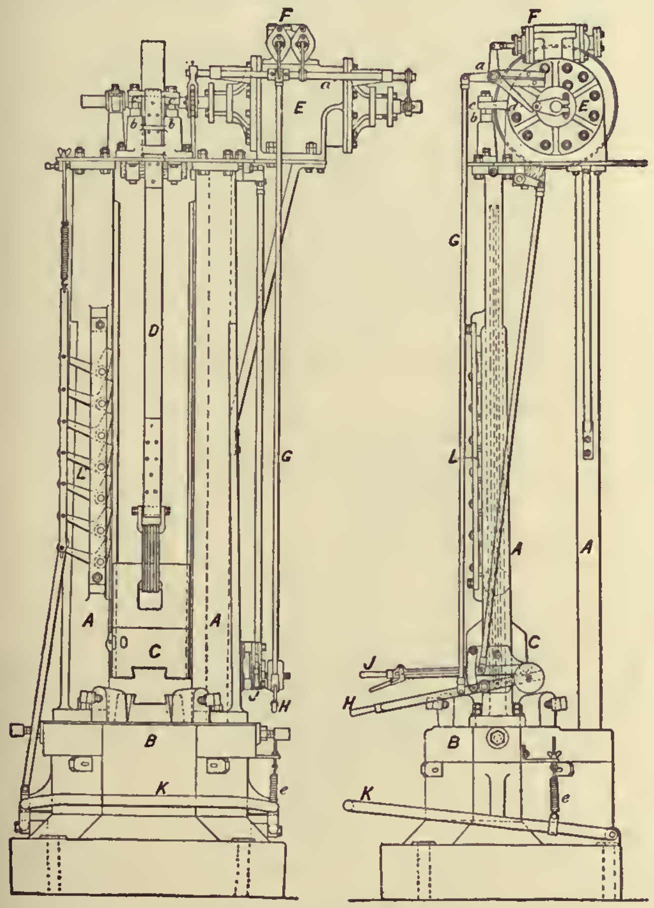

Fig. 60.—5 cwt. Belt Drop Hammer with Brett's Lifter. (Brett's Patent Lifter Co., Ltd., Coventry.)

A, *A*, Uprights.
B, Anvil.
C, Tup.
D, Belt.
E, Lifter cylinder.
F, Valve casing.
G, Rod operating valve by lever *H*.
a, Rock shaft.
b, Buffer blocks which arrest motion of lever *c*.
d, Lever for automatic regulation of valve.
J, Lever for regulating amount of opening of valve by hand.
K, Foot lever for holding tup in either of the stops *L*.
e, Spring for foot lever.

Spring Hammers are a rather smaller group than the others. In these a belt-driven pulley actuates the tup through the medium of elastic leaf springs. The length of stroke is adjustable across the face of a slotted disk on the driving shaft.

Forging Machines.—The Ryder forging machine is fitted with four or five pairs of swage tools, the lower halves being fixed and the upper ones driven by a rotating eccentric shaft. The operations imitate those on the anvil by hand forging, but from 800 to 1200 blows are delivered in a minute. The swages are arranged in succession, so that an operation is begun at one end and finished at the other, the attendant moving the bar rapidly through the successive swages or dies.

Forging Presses.—These are rivals to the hammers, especially for heavy forgings, from which hammers are being rapidly displaced (fig. 61). It is now well understood that a hammer will not effect the consolidation of a massive forging right to the centre as a press will. The force of the hammer blow is not transmitted to the centre as is that of a press, nor is the hammer so useful in work of large dimensions but of no great weight. In railway and wagon shops the presses are used far more frequently than the hammers. A great advantage of the press is that two and three rams can be brought into operation so that a forging may be pressed from above, from below and to one side, which is of great value in complicated forms and in welding, but is not practicable in the hammers. Hence the forging presses have become developed for work of average dimensions as well as for the most massive. Many are of horizontal type, termed bull-dozers.

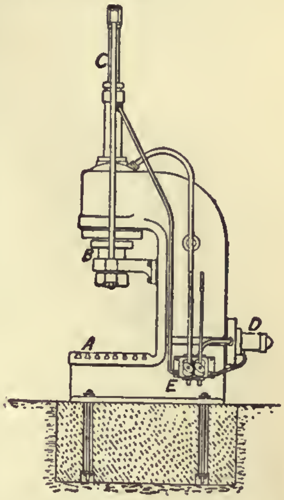

Fig. 61.—Hydraulic Forging Press. (Fielding & Platt, Ltd., Gloucester.)

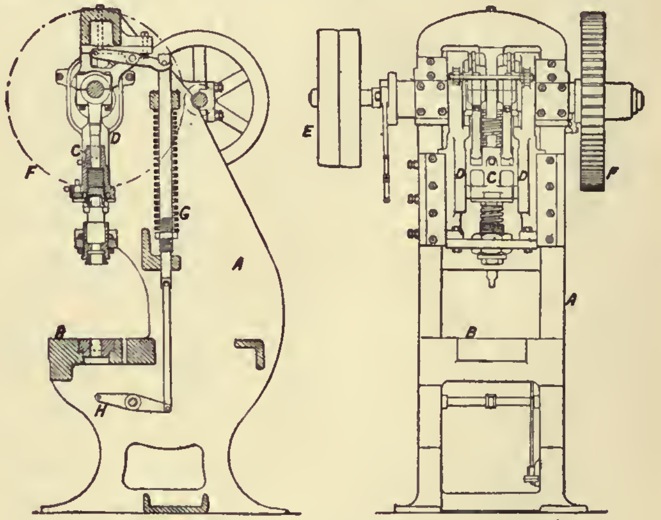
A, Table.
B, Vertical ram.
C, Drawback ram for returning *B*.
D, Horizontal ram.
E, Controlling valves.

Power presses for working sheet-metal articles include those for cutting out the blanks, termed cutting-out or blanking presses, and those for cupping or drawing the flat blank into shape if desired (fig. 62). The lower dies are held upon a bed, and the upper in a sliding ram, moved up and down by a cam or crank-shaft. A clutch mechanism is fitted, by means of which this shaft is connected with or disconnected from the heavy driving-wheel at will to give a single stroke or a series of strokes to the ram. In the normal state the ram remains stationary at the top position. The lightest presses are driven direct by belt on the crank-shaft pulley, but in the heavier classes spur-gearing must be interposed between the pulley shaft and the final shaft. The operation of drawing requires an encircling die which presses on the blank as it lies on its die, the cupping of the blank being effected by the downward motion of the plunger.



Sectional Elevation. Front Elevation.

Fig. 62.—Power Press.

A, Main frame.
B, Bed for attaching dies.
C, Central slide.
D, Outer slide.
E, Belt pulleys on shaft, geared to wheel *F* thrown in by clutch to drive its shaft, which has two crank pins to reciprocate *D* and a cam disk actuating *C*.
G Extractor rocked downwards as slide rises to raise lever *H* and work an ejector rod, forcing finished article out of die.

This is why the machine shown in fig. 62 has an outer slide *D*, which is made to "dwell" with an even pressure, while the middle ram is moving down and drawing out the article. Blanking and cupping may be done as one continuous operation if the work is shallow.

Inclinable presses are employed for certain classes of work, the object being to let the stamped articles slide down the slope of the bed as rapidly as they are produced, instead of having to be removed by the operator. Much work can be placed on the dies by hand, but for producing large quantities of small articles automatic feeds are employed whenever possible. A good deal of work is produced from flat sheet, supplied in the form of a roll and fed through rollers by intermittent movements to the dies. Circular turn-tables are also used, operated by ratchet devices, which turn the tables round to bring a ring of pockets, carrying the pieces, successively under the dies; the attendant keeps the pockets supplied, but his hands do not come near the dies.

X.—Portable Tools

The growth of portable machine tools is one of the remarkable movements of the present day. To some extent they have always been used, notably in the drilling and tapping operations of locomotive fire-boxes, but not until recently to any important extent in the ordinary fitting and erecting shops. The main reason lay in the difficulties due to transmission of power by ropes or shafts. The employment of compressed air, water, electricity and flexible shafts, by which long distances can be covered, has given new life to the portable system, which is destined to occupy a place of even greater importance than it does at present. The reason for the growing desirability of these tools is to be seen in the massive character of much engine and machine construction of the present time. Although firms that undertake the largest work can generally arrange to tool the individual parts on machines of massive sizes, that only meets a part of the difficulty. Very big work cannot be treated like that of small or even medium dimensions, done repetitively; that is, it is not practicable to drill and bore and ream and provide for the fitting of every piece by the aid of templets and jigs, while the work lies on the machine, but a great deal of adjustment and mutual fitting has to be accomplished in the course of erection. Therein lies the opportunity for the portable machine. If this is not used the alternatives are partial dismantling of the work and the transference of certain portions to machines or hand work. Another cause has been the substitution of machining for much hand work formerly done on massive constructions.

The principal operations for which portable tools are designed are the following: Drilling, screwing, cutting the seatings for keys, planing short portions of work, facings for the attachment of other pieces, as brackets and bearings, hammering operations, as in making welded joints, caulking the edges of boiler plates, chipping with hammer and chisel, riveting, ramming sand in foundry moulds, planing ships' decks, and some operations of lesser magnitude.

Portable tools are used in various ways. The first and most obvious is to attach them directly to the casting, forging or machine which is being built up. Thus a drilling machine will be clamped just where it is required to operate. Or if it has to be used on a large plane surface as a ship's deck, an electrical machine is suitable, in which magnetic attraction is set up between the foot of the machine and the deck sufficient to hold it down. A key-seating machine will be clamped on the shaft in which a keygroove has to be cut. A drilling machine may be fastened to a pipe with a chain embracing the pipe. Very many of the drills, and all the caulking and chipping hammers, are grasped in the hands and so thrust to their work. The tapping of screw holes is mostly done in this way, a common example being the holes for the stay bolts in the fire-boxes of steam boilers.

Another later method which has been introduced and practised in a few shops consists in installing a cast-iron floor-plate of large area, planed truly and provided with bolt holes and slots. On this a massive casting, forging or piece of work undergoing erection will be bolted. Then the portable tools—planers, drills, &c., as required—will be bolted to the table and brought into operation on the various sections of the work, several sometimes operating simultaneously. This method is to a certain extent coming into rivalry with the abnormal growth of machine tools, the development of which has been greatly accelerated by the massive dimensions of productions which only became possible by the substitution of steel made by the Bessemer and Siemens processes for iron.

The reciprocating motion necessary to effect hammering, chipping or caulking operations is produced by the action of a solid piston, sliding in a cylinder (fig. 63) and driven sharply against the end of the tool by the inrush of compressed air, being then returned for another stroke. The strokes range in number up to as many as 2000 per minute in some cases. For heavy riveting a "long-stroke" hammer is employed, having a longer barrel than the chipping hammer shown in fig. 63, in order to obtain a greater force of blow. The operator grasps the hammer by the handle, with his fingers or thumb on the controlling lever, and as long as this is held down the blows continue. The air-supply pipe is flexible, so that it does not impede the movements of the workman. The tools at the end of the cylinder are simply held in a socket, so that they can be changed rapidly.

Rotative motion can be produced either by electric or pneumatic motors, and both systems are in wide use. Pneumatic motors are very suitable when an air-compressing plant is already laid down for other tools, while if electricity is used in the works portable tools operated by this agent may be employed instead of the pneumatic ones. In the electric drills (fig. 64) a small motor is fitted within the body and connected by spur-gears to the spindle to effect suitable speed reduction. A switch provides for stopping and starting the motor; the current is brought through a flexible cable which, like pneumatic hose, is armoured with wire to protect it from damage. The smallest drills are simply gripped in the operator's hand and pushed up to the work; larger ones are supported by a pillar and arm, against which the thrust is taken, and the feed given by turning a screw at intervals.

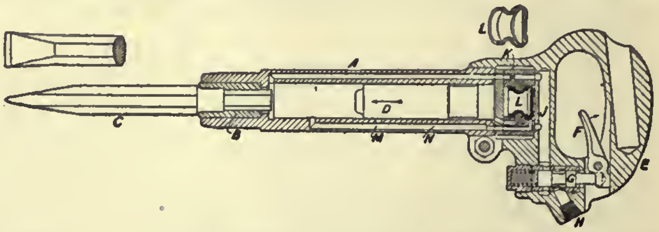


Fig. 63.—Tierney Pneumatic Chipping Hammer. (The Globe Pneumatic Engineering Co., Ltd.)

A, Cylinder.
B, Tool socket, carrying chisel *C*.
D, Piston, which strikes the back of *C*.
E, Handle, screwed and clamped to *A*.
F, Trigger or lever clasped by operator's hand and opening valve *G*, admitting compressed air through connexion *H*, up passage *J*, through valve-box *K*, past valve *L*, and so against end of *D*, moving it towards *C*. As soon as the groove in the piston *D* registers with the hole *M*, air is admitted from a small hole (not shown), passes round the groove through hole *M* and passage *N* to the rear of the valve. This acting on the back of the valve throws it forward, thus shutting off the supply to the rear of the piston and permitting a small quantity of air to flow to the forward end of the piston for driving it in a backward direction. As soon as the air pressure is relieved on the back of the valve by the uncovering of exhaust holes (not seen) by the piston *D*, the valve is returned to the original position, owing to the air constantly pressing on the small area of the valve.

B, Motor, with revolving armature *C*, connected by spur-gears *D*, to the drill spindle *E*, fitted with ball thrust bearings.
F, Switch, operated by attendant pushing in a plug; the current is brought by flexible wires through the right-hand handle *a*.

Pneumatic drills are usually worked by little motors having oscillating cylinders, by which the air and exhaust ports are covered and uncovered. They run at a high speed and are geared down to the spindle. In some cases two cylinders are used, but often four are fitted to give a powerful and equable turning moment. Grinding machines are also built with air motors directly coupled to the wheel spindle, the machines being moved about over the work by handles.

Another class of portable tools is driven, not by self-contained motors, but from an outside source of power, which is conveyed to the tools through flexible shafts built up of a series of spiral springs, or through flexible joints which form a connexion that permits the shaft to bend round corners and accommodate itself to any position in which the tool may be placed. The advantage of this is that the tool itself is much lightened, since there is no motor, and it can therefore be easily handled. Thus a drill simply contains the spindle, running in a frame which carries bevel-gears for transmitting the motion of the flexible shaft. Portable grinders also have nothing but the spindle, wheel and frame.

XI.—Appliances

Appliances are vastly more numerous in a modern shop than in the older works, largely on account of the more repetitive character of the operations done and of the desire to eliminate human labour, with its greater cost and chances of inaccuracy in the finished product. On all machines there are numerous aids by which the fixing of the work is facilitated. Many of these consist of simple packing blocks, by which heights are adjusted. These reach their higher developments in wedge-shaped packings, some of which are operated by a screw, while others act directly by screws. In some cases the exact height can be ascertained by observing graduations on the packings. Circular work is held in V-blocks, which occur in numerous modified forms. Various kinds of straps, clamps and bolts are used for gripping work with sufficient security to enable it to withstand the stress of the heaviest cutting. The highest development of all is attained in the templets and jigs, which are now indispensable in all modern shops, and which increase in number and complexity as the product of the shop becomes more specialized. A templet is a piece of metal cut to a definite shape, which being laid upon the work becomes a guide for striking the same shape on the surface of the work with a pointed scriber, and by which the tooling of any number of similar pieces is done without the labour of lining out each separate piece. Obviously, in such a case the degree of accuracy of the tooling still depends on the machine hand, who may work exactly, or only approximately, to these lines. Hence a great advance is made in the jig, which may be defined generally as a templet that is clamped rigidly to the work, or a box in which the work to be tooled is held. No marking off is done, but the jig becomes the actual guide for the operation of the cutting tools. The operation most frequently performed in jigs is drilling. Then the holes in the jig receive and coerce the drills, so that the holes made cannot vary in the least degree from those already in the jig. As it will often happen that hundreds or thousands of similar pieces will have to be tooled in this manner, holes in jigs are generally bushed with hardened steel, which is capable of enduring very lengthy service, and which can be renewed when worn. This is a simple illustration, but many jigs are of an extremely elaborate character, for it is obvious that the cost of a jig, though it may run into many pounds, becomes a mere trifle when spread over some thousands of pieces of work.

XII.—Wood-working Machinery

There is a large range of various classes of tools for performing the operations on timber, from the rough log to the finished product. Division is effected by saws, planing and finishing to outlines by knives or cutters, boring by augers and smoothing by sandpaper.

The first operation is that of tree-felling, which is often effected by machine, consisting of a reciprocating blade, working horizontally in a frame and moved by a steam cylinder. The boiler is separate, so that the machine may be transported about and set to work over a considerable area, steam being conveyed to it by a flexible pipe. When the trees are brought into the saw-mills in the form of logs, *i.e.* with the branches lopped off, they are often cross-cut to reduce them to suitable lengths. This operation is effected either by a reciprocating saw, operated by a pulley and crank, or by an electric motor, or else with a circular saw, travelling on a carriage which moves the saw through the log laid in front of it. The next operation, that of division or breaking-down into smaller portions, is done by saws of various types, according to the class of work. The oldest form of machine is the frame-saw, which is still used very largely. It comprises a framing within which a saw-gate or saw-frame is reciprocated up and down by a crank; the frame holds a number of saws or webs of flat form, strained up tightly with wedges or cotters between the top and bottom of the frame, the distance between the saws being capable of variation to suit boards of all thicknesses. The log is fed longitudinally to the gang of saws upon carriages, which are of two types. In the roller-feed, which is suitable for comparatively even and straight logs, ribbed rollers in front and behind the saws obtain a bite on the top and bottom of the timber and feed it forward by their rotation. In the rack-feed the log is mounted bodily upon a long carriage that runs by rollers upon a set of rails, and the carriage is travelled along by pinions and racks, which give a positive feed regardless of the shape of the log. The carriage in the roller-feed machines is only represented by a couple of plain trolleys supporting the timber at back and front. The feed is obtained through a friction wheel of V-shape, with a smooth pawl, called the silent feed; the wheel is given a partial rotation at each down stroke of the saw-gate to turn the rollers or the pinions for carrying forward the log. The division of the timber may be either into deals or flitches, or planks or boards. In the last-named case as many as fifty saw-blades are sometimes held in a frame.

For the more valuable hardwoods a single blade reciprocating saw, operated horizontally, is used very largely, the machine being termed a board-cutter. The log is clamped to a travelling table, passing underneath the saw, which is strained in a frame sliding on a cross-rail that can be adjusted up or down on a couple of uprights like a planing machine. The saw is worked from a crank and connecting-rod. As only one board is sawn at a time the attendant is able to see the figuring of the timber and to avoid waste when bad places are encountered.

A machine much more rapid in operation is the horizontal band-saw, modelled on the lines of the above machine, but with a band-saw blade running over two pulleys, at a high speed, of about 7000 ft. per minute. The saws are very thin, so that a minimum of wood is wasted in the cut or "kerf," a very important consideration in dealing with costly woods. Vertical band-saws, having one pulley above the other so that the blade runs vertically, are very popular in America; they occupy less floor space than the horizontal types. It is necessary to present the log from the side, and it is therefore clamped by dogs upon a carriage running on rails, with provision for feeding the log laterally to the saw by sliding ways on the carriage.

The use of circular saws for breaking-down is confined chiefly to squaring up heavy balks, which need only a cut on each side, or for cutting thick slabs. The thickness of the saw entails considerable waste of wood, and a large amount of power is required for driving. The machines are termed rack-benches, and comprise a long divided table built up of thin plates and travelling past the fixed saw upon rollers, the movement being effected by a rack and pinion.

Re-sawing machines are those designed for further cutting-up deals, flitches, planks, &c., already broken out from the log, into boards and other scantlings. The deal and flitch frames are built on the model of the frame-saws first described, but with the differences that roller feed is always used, because the stuff is smooth and easily fed, and that the back of the timber is run against fences to keep it moving in a straight line. In the double equilibrium frames, which are much favoured, there are two sets of saws in separate frames connected by rods to opposite crank-shafts, so that as one frame is rising the other is going down; the forces are thus balanced and vibration is diminished, so that the machines can be speeded rather higher. Re-sawing is also done on circular and band saws of various types, fitted with fences for guiding the timber and controlling the thicknesses.

The cross-cut saws constitute another large group. They are employed for cutting-off various classes of stuff, after breaking-down or re-sawing, and are of circular saw type. The pendulum saw is a suspended form, comprising a circular saw at the bottom of a hanging arm, which can be pulled over by the attendant to draw the saw through a piece of wood laid on a bench beneath. Circular saws are also mounted in tables or benches and made to part off stuff moved laterally upon a sliding-table. When there is sufficient repetition work machines with two or more saws are used to cut one or more pieces to accurate length without the necessity for measurement.

The lighter classes of circular and band-saws, employed for sawing up comparatively small pieces of timber, embody numerous provisions for quickening output. The plain saw benches, with circular saws, are the simplest class, consisting merely of a framed table or bench carrying bearings for the saw spindle and a fence on the top to guide the wood. A mechanical feed is incorporated in the heavier machines to push the timber along. The rope-feed mechanism includes a drum driven at varying rates and giving motion to a rope, which is connected with a hook to the timber, to drag it along past the saw, roller supports on rails taking the weight at each end of the bench. Roller-feed saws propel the stuff by the contact of vertical fluted rollers placed opposite the fence. Other classes of saws for joinery work, &c., are constructed with rising and falling spindles, so that the saw may be made to project more or less from the table, this provision being necessary in grooving and tonguing with special types of saws. The same effect is obtained by making the table instead of the spindle rise and fall.

As it is necessary to use different saws for ripping (with the grain) and cross-cutting, some machines embody two saws so that work can be cut to shape on the same machine. These "dimension saws" have two spindles at the opposite ends of a pivoted arm that can be turned on a central pin to bring one or the other saw above as required. In cases where much angular and intricate sawing is done universal benches are employed, having in addition to the double saws a tilting motion to the table, which in conjunction with various special fittings enables the sawyer to produce a large range of pieces for any class of construction.

Band-saws, which have a thin narrow blade, are adapted especially for curved sawing and cutting-out work which the circular saw cannot manage. The usual design of machine (fig. 65) comprises a stiff standard supporting a lower pulley in fixed bearings, and an upper one in a sliding bearing, which by means of a weight or spring is caused to rise and maintain an even tension on the saw blade as it is driven by the lower pulley, and runs the upper one. India-rubber tires are placed around the pulley rims to prevent damage to the saw teeth. The table, placed between the pulleys, may be angled for cutting bevel work. It is necessary, in order to do true work, to guide the saw blade above and below the cut, and it is therefore run in guides consisting of flat strips, in combination with anti-friction rollers which take the backward thrust of the saw. Fret or jig saws are a small class with a vertical reciprocating blade, employed chiefly for cutting out interior portions which necessitate threading the saw first through a hole.

Planing machines, used for truing up the surfaces of wood after sawing, depend for their action upon rapidly revolving knives fastened to flat-sided cutter blocks. The simplest machines, the hand-planers, have a cutter cylinder revolving between two flat table slides adjustable for height to support the wood while it is pushed along over the knives by the hand. A fence guides it in a straight line. Exact thicknessing is done on another type of machine, the panel planer or thicknesser, in which the cutter cylinder revolves above the table and the stuff is fed through by rollers above

and below. By altering the height of the table the thickness of wood can be varied. Double machines include a cutter cylinder above and below the timber, so that the upper and under sides are planed simultaneously. A combination of the hand-planer and the thicknesser is useful in cases where space or expenditure must be limited.

When large quantities of planed stuff are wanted, such as for flooring-boards, &c., other types of machines are employed. The four-cutter planers are the most rapid in output, and the timber is passed through them at a high rate, ranging up to 150 ft. per minute. There is first a revolving cutter cylinder, which roughs off the underside of the stuff, whence it passes (being propelled by rollers) to a fixed knife which imparts a very smooth face. A little farther on in the machine two vertical cutter blocks are encountered which carry cutters to plane or tongue or mould the edges, after which another cylinder above finishes the top face. Similar types of machines are made to produce mouldings, using four cutters shaped to suit the pattern required.

Moulding is also done on the vertical spindle shapers, which carry a cutter or cutters at the top of a spindle projecting through a flat table. The work is slid over the table and controlled by touching a collar below the cutter. Any form may be given to the cutters to produce different profiles. Some special moulding machines use a cutter at the end of a spindle projecting downwards from an arm overhanging a table, an arrangement which enables recessing and carving to be performed.

Boring machines comprise rotating spindles and feeding mechanism to actuate augers. The single spindle machines are satisfactory enough for ordinary work, but when a number of differently sized holes have to be bored in a single piece of work, or in rapid succession, it is the practice to employ a machine with a number of spindles, so that a succession of augers of graduated diameters may be ready to use at will.

Mortising or cutting slots is done in vertical machines with a reciprocating spindle, operated either by hand or by crank disk and pulleys. The tool that cuts the mortise resembles a wood-worker's chisel, but is of stouter form and has a suitable shank to fit in the spindle. The latter can be reversed to turn round and let the chisel face in the opposite direction for cutting at each end of a

mortise. A boring spindle is often incorporated with the machine to make holes for the mortising chisel to start in (fig. 66). Another class of mortiser employs a square hollow chisel, inside of which an auger rotates and first bores a hole, leaving to the chisel the duty of finishing out the corners. The chain mortiser is another type; it has an endless chain of flat links, sharpened to make cutting teeth, and is run around a bar and a roller at a high speed, so that when fed into the wood a recess or mortise is cut out.

Tenoning machines, designed to cut the reduced ends or tenons to fit in mortises, perform their work by the aid of cutter blocks, revolved on horizontal spindles above and below the timber, which is fed laterally upon a sliding carriage.

Dovetailing is effected by revolving cutters in machines having mechanism for pitching out the cuts, or if the work warrants it an entire row of dovetails is made at one traverse, by fitting a row of cutters and feeding simultaneously. Corner-locking, or cutting parallel tongues and grooves in the edges of boxes, &c., is a rather more rapid operation than dovetailing, and is done with suitable cutter blocks or disks of appropriate thickness and pitching apart.

The general joiner, as its name implies, will do a large variety of operations, and is used in shops and on estates where a complete plant of machines would be out of the question. It usually has a circular saw and sometimes a band-saw also, together with planing and moulding apparatus, a moulding spindle, boring spindle and tenoning apparatus.

The lathes used in woodworking comprise the plain hand types with a simple T-rest on which the turner rests the tools to deal with the work revolving between centres, and the copying or Blanchard lathes, in which a master form or copy is rotated and caused by the contact and coercion of a roller to move the cutter rest in a corresponding fashion, so that the work is cut away until it exactly matches the shape of the copy.

Sand-papering machines, which finish the surface of wood to a high degree, deal with both flat and curved faces. Flat boards, panels, &c., can be done by contact against revolving drums or disks covered with glass-paper, being fed along over them by hand or by rotating rollers. In one class of machine a revolving disk is placed at the end of a series of jointed arms, by which the disk can be moved about over the work resting on a table underneath.

XIII.—Measurement

An advance of the greatest importance made in mechanical engineering is that of measurement. Since the beginning of the 19th century steady movement has been going on in this direction until it seems impossible that much greater refinement can now be looked for. Probably the chief advances to be expected will lie in the general extension in workshop practice of the knowledge already acquired, rather than in the acquisition of higher degrees of refinement.

Methods of measurement adopted in woodworking have but little application in high-class engineers' work. They are adopted, however, to a considerable extent in the metal trades which are allied to engineering, as sheet metal working, girder work, &c. When a carpenter or joiner sets about constructing a door, window sash, roof or box he takes a two-foot rule, a flat lead pencil, and marks off the dimensions and lines by which he intends to work. If he has to work very carefully, then instead of using a pencil he cuts a line with the edge of a keen scriber or chisel-like tool, by which to saw, plane or chisel. If outlines are curved, the compasses are brought into requisition, and these cut a fine line or lines on the surface of the wood. But in any case the eye alone judges of the coincidence of the cutting with the lines marked. Whether the tool used be saw, chisel, gouge or plane, the woodworker estimates by sight alone whether or not the lines marked are worked by.

The broad difference between his method and that of the engineer's machinist lies in this, that while the first tests his work by the eye, the second judges of its accuracy or otherwise by the sense of touch. It may seem that there cannot be very much difference in these two methods, but there is. To the first, the sixty-fourth part of an inch is a fine dimension, to the second one-thousandth of an inch is rather coarse. Now the thickness of tissue paper is about one-thousandth of an inch, and no one could possibly work so closely as that by the eye alone. Engineers' steel rules usually have one inch which is divided into one hundred parts. Tolerably keen sight is required to distinguish those divisions, and few could work by them by ocular measurement alone, that is, by placing them in direct juxtaposition with the work. A thousandth part of an inch seems by comparison a fine dimension. But it is very coarse when considered in relation to modern methods of measurement. In what are called "limit gauges" the plugs and rings are made of slightly different dimensions. If a plug is made a thousandth of an inch less than its ring it will slip through it easily with very perceptible slop. The common rule is therefore scarcely seen in modern machine shop, while the common calipers fill but a secondary place, their function having been invaded by the gauges. A minute dimension cannot be tested by lines of division on a rule, neither can a dimension which should be fixed be tested with high precision with a movable caliper of ordinary type. Yet it must not be supposed that the adoption of the system of gauging instead of the older methods of rule measurement relieves men of responsibility. The instruments of precision require delicate handling. Rough forcing of gauges will not yield correct results. A clumsy workman is as much out of place in a modern machine shop as he would be in a watch factory. Without correctness of measurement mechanical constructions would be impossible, and the older device of mutual fitting of parts is of lessening value in face of the growth of the interchangeable system, of international standards, and of automatic machine tools which are run with no intervention save that of feeding stock.

The two broad divisions of measurement by sight and by contact are represented in a vast number of instruments. To the first-named belong the numerous rules in wood and metal and with English and metric divisions, and the scales which are used for setting out dimensions on drawings smaller than those of the real objects, but strictly proportional thereto. The second include all the gauges. These are either fixed or movable, an important subdivision. The first embrace two groups—one for daily workshop service, the other for testing and correcting the wear of these, hence termed "reference gauges." They are either made to exact standard sizes, or they embody "limits of tolerance," that is, allowances for certain classes of fits, and for the minute degrees of inaccuracy which are permissible in an interchangeable system of manufacture. The movable group includes a movable portion, either corresponding with one leg of a caliper or having an adjustable rod, with provision for precise measurement in the form of a vernier or of a screw thread divided micrometrically. These may be of general character for testing internal or external diameters, or for special functions as screw threads. Subtitles indicate some particular aspect or design of the gauges, as "plug and ring," "caliper," "horseshoe," "depth," "rod," "end measure," &c. So severe are the requirements demanded of instruments of measurement that the manufacture of the finer kinds remains a speciality in the hands of a very few firms. The cost and experience necessary are so great that prices rule high for the best instruments. As these, however, are not required for ordinary workshop use, two or three grades are manufactured, the limits of inaccuracy being usually stated and a guarantee given that these are not exceeded.

Measurement by Sight. Rules and Scales.—The rules are used for marking off distances and dimensions in conjunction with other instruments, as scribers, compasses, dividers, squares; and for testing and checking dimensions when marked, and work in course of reduction or erection, directly or from calipers. They are made in boxwood and in steel, the latter being either rigid or flexible, as when required to go round curves. Rules are fitted in combination with other instruments, as sliding calipers, squares, depth gauges, &c. The scales are of boxwood, of ivory, the value of which is discounted by its shrinkage, and of paper. They are of flat section with bevelled edges, and of oval and of triangular sections, each giving a thin edge to facilitate readings. They are fully divided, or open divided; in the first case each division is alike subdivided, in the second only the end ones are thus treated.

The Gauges. Fixed Gauges.—These now embrace several kinds, the typical forms being represented by the cylindrical or plug and ring gauges and by the caliper form or snap gauges. The principle in each is that a definite dimension being embodied in the gauge, the workman has not to refer to the rule, either directly or through the medium of a caliper. This distinction, though slight, is of immense importance in modern manufacturing. Broadly it corresponds with the difference between the older heterogeneous and the present interchangeable systems.

Plug and Ring Gauges.—The principal ones and the originals of all the rest, termed Whitworth gauges after the inventor, are the plug and ring gauges (fig. 67, *A* and *B*). The principle on which they depend is that if the two gauges are made to fit with perfect accuracy, without tightness on the one hand or slop on the other, then any work which is measured or turned and bored or ground by them will also fit with equal accuracy. Bored holes are tested by the plug gauge, and spindles are tested by the ring gauge, and such spindles and holes make a close fit if the work is done carefully. Of course, in practice, there is very much variation in the character of the work done, and the finest gauges are too fine for a large proportion of engineers' work. It is possible to make these gauges within $\frac{1}{50000}$ of an inch. But they are seldom required so fine as that for shop use; $\frac{1}{5000}$ is generally fine enough. For general shop work the gauges are made to within about $\frac{1}{1000}$ of an inch. Standard gauges in which the plug and ring are of the same diameter will only fit by the application of a thin film of oil and by keeping the plug in slight movement within the ring. Without these precautions the two would "seize" so hard that they could not be separated without force and injury.

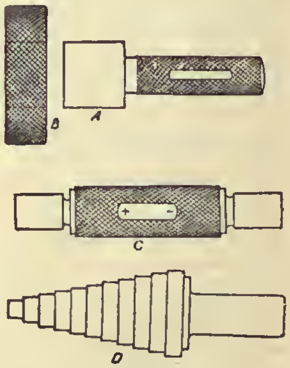

Fig. 67.

A, *B*, Plug and ring gauges.
C, Difference gauge.
D, Stepped reference gauge.

Plug and Ring v. *Horseshoe Gauges.*—The horseshoe, snap or caliper gauges (fig. 68) are often used in preference to the plug and ring types. They are preferred because the surfaces in contact are narrow. These occur in various designs, with and without handles, separately and in combination and in a much larger range of dimensions than the plug and ring. Ring gauges are not quite such delicate instruments as the fixed caliper gauges. But since they measure diameter only, and turned work is not always quite circular, the caliper gauges are not so convenient for measurement as the round gauges, which fit in the same manner as the parts have to fit to one another.

Fixed Gauges. Limit Gauges.—Some fits have to be what is termed in the shops "driving fits," that is, so tight that they have to be effected by driving with a hammer or a press, while others have to be "working fits," suitable, say, for the revolution of a loose pulley on its shaft or of an axle in its bearings. The "limit" or "difference gauges" (figs. 67 and 68) are designed for producing these working fits; that is, the plug and ring gauges differ in dimensions so that the work bored will drive tightly, or slide freely over

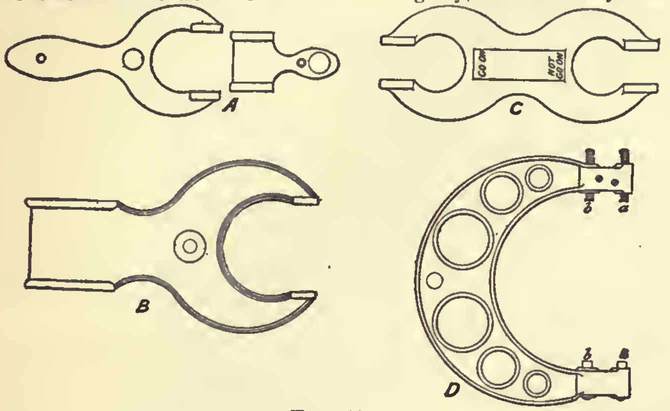

FIG. 68.

A, Separate caliper or snap gauges.
B, Combined internal and external gauges.
C, Difference gauge.
D, Newall adjustable limit gauge.
a, *b*, Plugs.

the work turned. These are variously sub-classified. The system which is generally accepted is embodied in the gauges by the Newall Engineering Co. These embrace *force fits*, which require the application of a screw or hydraulic press; *driving fits*, that require less power, as that of a hammer; *push fits*, in which a spindle can be thrust into its hole by hand; and *running fits*, such as that of shafts in bearings. Fixed gauges are made for each of these, but as this involves a heavy outlay the Newall firm have adjustable limit gauges (fig. 68, *D*) for external dimensions, the standard plug being used for holes. The setting is done by screwed plugs or anvils adjusted by reference bars. In all these gauges the "go on" and "not go on" ends respectively are stamped on the gauge, or the equivalents of + and −.

Fixed Reference Gauges. Reference Disks and End Measuring Rods.—Shop working gauges become in time so damaged by service that they fail to measure so accurately as when new. To correct these errors reference gauges are provided, by which the inaccuracy of the worn ones is brought to the test. These are never used in the shops for actual measurement of work, but are only kept for checking the truth of the working gauges. They include disk, stepped and end measurement gauges. The disk and the stepped are used for testing the ring gauges, the stepped kind comprising essentially a collection of disks in one piece (fig. 67, *D*). The end measure pieces test the external gauges. The end measure standard lengths made by the Pratt & Whitney Co. are so accurate that any sizes taken at random in any numbers from ¼ in. to 4 in., varying by sixteenths of an inch, will, when placed end to end, make up an exact length; this is a difficult test, since slight variations in the lengths of the components would add up materially when multiplied by the number of pieces. The ends are ground off with diamond dust or emery in a special machine under water, and are so true that one piece will support another by cohesive force, and this though the surfaces are less than ¼ in. square.

Movable Gauges.—This extensive group may be regarded as compounded of the common caliper and the Whitworth measuring machine. They are required when precise dimensions have to be ascertained in whole numbers and minute fractional parts. They combine the sense of touch by contact, as in the calipers, with the exact dimensions obtained by inspection of graduated scales, either the vernier or the micrometer screw. If gauges must not vary by more than $\frac{1}{10000}$ of an inch, which is the limit imposed by modern shop ideals, then instruments must be capable of measuring to finer dimensions than this. Hence, while the coarser classes of micrometers read directly to $\frac{1}{1000}$ part of an inch, the finest measure up to $\frac{1}{100000}$ of an inch, about 200 times as fine as the diameter of a human hair. They range in price correspondingly from about a sovereign to £100.

The Calipers.—Common calipers (fig. 69) are adjusted over or within work, and the dimensions are taken therefrom by a rule or a gauge. They usually have no provision for minute adjustment beyond the gentle tapping of one of the legs when setting. In some forms screw adjustment is provided, and in a few instances a vernier attachment on the side of the pivot opposite to the legs.

Vernier Calipers.—The vernier fitting, so named after its inventor, Pierre Vernier, in 1631, is fitted to numerous calipers and caliper rules. It is applied to calipers for engineers' use to read to $\frac{1}{1000}$ of an inch without requiring a magnifier. The beam of the caliper is divided into inches and tenths of the inch, and each tenth into fourths and the vernier into twenty-five parts, or the beam is divided into fiftieths of an inch (fig. 70) and the vernier has 20 divisions to 19 on the rule. The caliper jaws are adapted to take both external and internal dimensions. These "beam calipers" are also made for metric divisions. Minor variations in design by different manufacturers are numerous.

A, Hollow base or bed, mounted on three points.
B, Measuring or fast headstock.
C, Movable head, or tailstock.
D, Spirit-level to indicate alterations in length of piece being measured due to changes in temperature, termed the indicator or comparator.
E, Measuring screw.
F, Nut for rapid adjustment of ditto.
G, Knob of speed screw for slow movement of ditto.
H, Dividing and measuring wheel.
J, Vernier or reading bar.
a, *a*, Points between which contact is made.

Micrometer Calipers are the direct offspring of the Whitworth measuring machine. In the original form of this machine a screw of 20 threads to the inch, turned by a worm-wheel of 200 teeth and single-threaded worm, had a wheel on the axis of the worm with 250 divisions on its circumference, so that an adjustment of $\frac{1}{1000000}$ of an inch was possible. The costly measuring machines made to-day have a dividing wheel on the screw, but they combine modifications to ensure freedom from error, the fruits of prolonged experience. Good machines are made by the Whitworth, the Pratt & Whitney, the Newall (fig. 71), and the Brown & Sharpe firms. These are used for testing purposes. But there are immense numbers of small instruments, the micrometer calipers (fig. 72), made for general shop use, measuring directly to $\frac{1}{1000}$ of an inch, and in the

e, Anvil.

pitch is 40 to the inch, and the circular divisions number 25, so that a movement of one division indicates that the screw has been advanced $\frac{1}{25}$ of $\frac{1}{40}$ or $\frac{1}{1000}$ of an inch. Provision for correcting or taking up the effects of wear is included in these designs (*e.g.* at *a* in fig. 72), and varies with different manufacturers. A vernier is sometimes fitted in addition, in very high class instruments, to the circular divisions, so that readings of ten thousandths of an inch can be taken. Beam micrometer calipers (fig. 73) take several inches in length, the micrometer being reserved for fractional parts of the inch only.

Depth Gauges.—It is often necessary to measure the depth of one portion of a piece of work below another part, or the height of one portion relatively to a lower one. To hold a rule perpendicularly and take a sight is not an accurate method, because the same objections apply to this as to rule measurement in general. There are many depth gauges made with rule divisions simply, and then these have the advantage of a shouldered face which rests upon the upper portion of the work and from which the rule measurement is

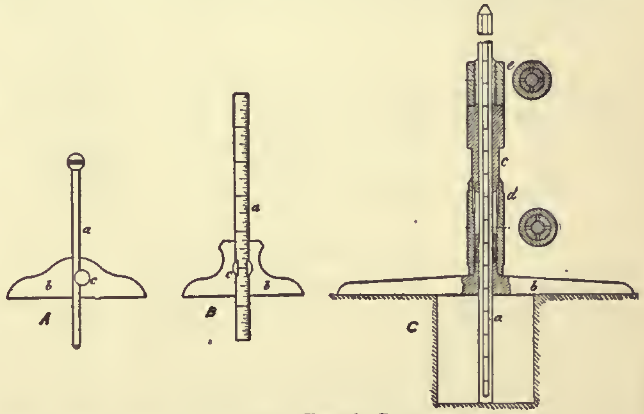

FIG. 74.—Depth Gauges.

A, Plain round rod *a*, sliding in head *b*, and pinched with screw *c*.
B, Rule *a*, graduated into inches or metric divisions, sliding on head *b*, in grooved head of clamping screw *c*.
C, Slocomb depth gauge, fitted with micrometer. *a*, Rod marked in half inches, sliding in head *b*; *c*, hub; *d*, thimble corresponding with similar divided parts in the micrometer calipers; *e*, clamping screw.

taken (fig. 74). These generally have a clamping arrangement. But for very accurate work either the vernier or the micrometer fitting is applied, so that depths can be measured in thousandths of an inch, or sometimes in sixty-fourths, or in metric subdivisions.

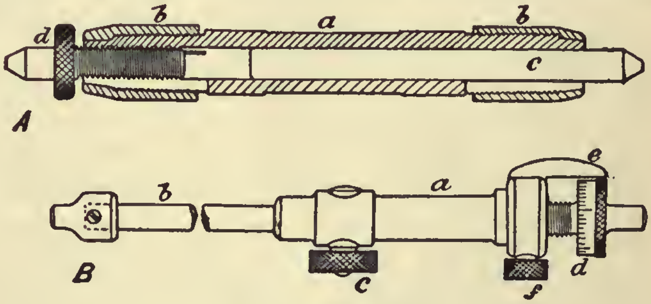

FIG. 75.—Rod Gauges.

A, Pratt & Whitney gauge. *a*, Tube split at ends; *b*, *b*, chucks clamping tube on plain rod *c*, and screwed end *d*. Rough adjustment is made on rod *c*, of which several are provided; fine adjustment is by screwed end *d*.
B, Sawyer gauge. *a*, Body; *b*, extension rods for rough adjustment, several being supplied and pinched with screw *c*; *d*, screwed end with graduated head; *e*, reading arm extending from body over graduations; *f*, clamping screw.

Rod Gauges.—When internal diameters have to be taken, too large for plug gauges or calipers to span, the usual custom is to set a rod of iron or steel across, file it till it fits the bore, and then measure its length with a rule. More accurate as well as adjustable are the rod gauges (fig. 75) to which the vernier or the micrometer are fitted. These occur in a few varied designs.

Screw Thread Gauges.—The taking of linear dimensions, though provided for so admirably by the systems of gauging just discussed, does not cover the important section of screw measurement. This is a department of the highest importance. In most English shops the only test to-day of the size of a screw or nut is the use of a standard screw or nut. That there is variation in these is evidenced by the necessity for fitting nuts to bolts when large numbers of these are being assembled, after they have been used in temporary erections or when nuts are brought from the stores to fit studs or bolts cut in the shop. This method may suffice in many classes of work, but it is utterly unsuited to an interchangeable system; and when there is a fair amount of the latter firms sometimes make thread gauges of their own, in general form like the plug and ring gauges, using a hard quality of steel for small sizes or a tough quality of cast iron for the larger. These, though not hardened, will endure for a long time if treated carefully. But

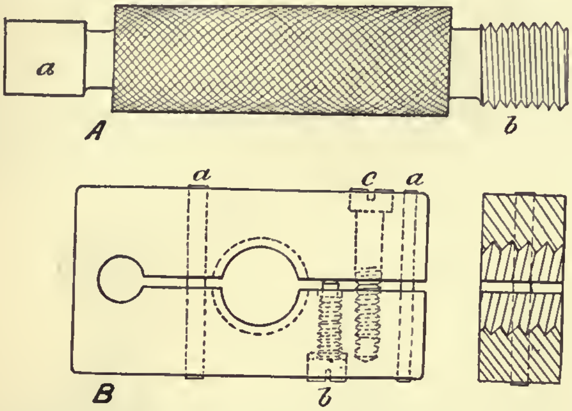

Fig. 76.—Screw Thread Gauges. (Pratt & Whitney Co.)

B, Ring gauge; *a*, pins to prevent lateral movement; *b*, adjusting screw for opening gauge; *c*, screw for closing ditto.

though very useful and far better than none at all they lack two essentials. They are simply accommodation gauges, made to an existing tap or die, and do not therefore embody any precise absolute measurement, nor do they include any means for measuring variations from standard, nor are they hardened. To produce gauges to fulfil these requirements demands an original standard to work by, micrometric measurements, and the means of grinding after the hardening process. These requirements are fulfilled in the screw thread gauges and calipers of the Pratt & Whitney and the Brown & Sharpe companies. The essential feature of a screw gauge is that it measures the sides of the threads without risk of a possible false reading due to contact on the bottom or top of the V. This is fulfilled by flatting the top and making the bottom of the gauge keen. The Pratt & Whitney gauges are made as a plug and ring (fig. 76), the plug being solid and the ring capable of precise adjustment round it. There is a plain round end, ground and lapped exactly to the standard size of the bottom of the thread, a dimension which is obliterated in the threaded end because of the bottoms of the angles being made keen for clearance. There are three kinds of this class of gauge made; the first and most expensive is hardened and ground in the angle, while the second is hardened but not ground. The first is intended for use when a very perfect gauge is required, the second for ordinary shop usage. The third is made unhardened for purposes of reference simply, and it is not brought into contact with the work to be tested at all, but measurements are taken by calipers; in every detail it represents the standard threads. The Brown & Sharpe appliance is of quite a different character. It is a micrometer caliper having a fixed V and a movable point between which the screw to be measured is embraced. By the reading of the micrometer and the use of a constant the diameter of any thread in the middle of the thread can be estimated.

Miscellaneous.—The foregoing do not exhaust the gauges. There are gauges for the sectional shapes of screw threads of all pitches, gauges for drilled holes that have to be screwed, gauges for the depth and thickness of the teeth of gear-wheels, gauges for the tapers of machine spindles, gauges for key-grooves, &c. There are also the woodworker's gauges—the marking and cutting, the panel, the mortise and the long-tooth.

Indicators are a small group of measuring instruments of a rather peculiar character. They magnify the most minute error by adaptations of long and short lever arms. The Bath, the Starrett and the Brown & Sharpe are familiar in high-class shops. Some simply magnify inaccuracy, but in one type an index reads to thousandths of an inch (fig. 77). They are used in some kinds of lathe chuck work, but their principal value is in fitting and erecting the finer mechanisms.

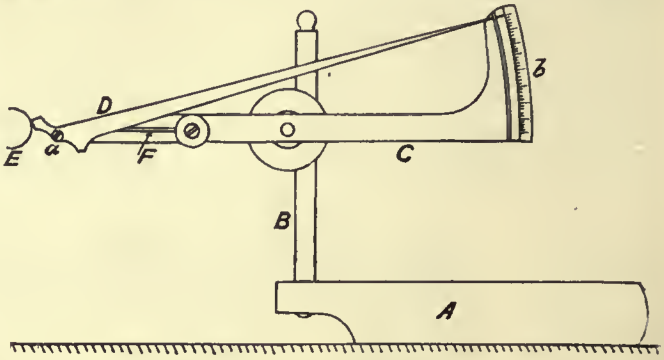

Fig. 77.—Indicator.

A, Base; *B*, stem; *C*, arm; *D*, pointer or feeler, pivoted at *a*, and magnifying movement of the work *E* upon the scale *b*; *F*, spring to return *D* to zero.

Surface Plates and Cognate Forms.—Allied to the gauges are the instruments for testing the truth of plane surfaces: the surface plates, straight-edges and winding strips. The origination of plane surfaces by scraping, until the mutual coincidence of three plates is secured, was due to Whitworth. These surface plates (fig. 78, *A*) fill an important place in workshop practice, since in the best work plane surfaces are tested on them and corrected by scraping. To a large extent the precision grinding machines have lessened the value of scraping, but it is still retained for machine slides and other work of a similar class. In the shops there are two classes of surface plates: those employed daily about the shops, the accuracy of which becomes impaired in time, and the standard plate or plates employed for test and correction. Straight-edges are derived from the surface plates, or may be originated like them. The largest are made of cast-iron, ribbed and curved on one edge, to prevent flexure, and provided with feet (fig. 78, B). But the smaller straight-edges are generally parallel, and a similar pair constitutes "winding strips," by which any twist or departure from a plane surface is detected. Squares, of which there are numerous designs (fig. 78, *C* and *D*), are straight-edges set at right angles. Bevels or bevel-squares (fig. 79), are straight-edges comprising a stock and a blade, which are adjustable for angle in relation to each other. Shop protractors often include a blade adjustable for angle, forming a bevel with graduations. Spirit-levels test the horizontal truth of surfaces. Many levels have two bubble tubes at right angles with each other, one of which tests the truth of vertical faces. Generally levels have flat feet, but some are made of V-section to fit over shafting. The common plumb-bob is in frequent use for locating the vertical position of centres not in the same horizontal plane. When a

plumb-bob is combined with a parallel straight-edge the term plumb-rule is applied. It tests the truth of vertical surface more accurately than a spirit-level. (J. G. H.)

TOOLE, JOHN LAWRENCE (1832–1906), English actor, son of an old employé of the East India Company who for many years acted as toast-master in the City of London, was born in London on the 12th of March 1832. He was educated at the City of London School, and started life in a wine merchant's office; but his natural propensity for comic acting was not to be denied, and after some practice as an amateur with the City Histrionic Club, he definitely took to the stage in 1852, appearing in Dublin as Simmons in *The Spitalfields Weaver*. He gained experience in the provinces, and in 1854 made his first professional appearance in London at the St James's theatre, acting Samuel Pepys in *The King's Rival* and Weazel in *My Friend the Major*. In 1857, having just had a great success as Paul Pry, he met Henry Irving in Edinburgh, and recommended him to go to London; and their friendship remained thenceforth of the closest kind. In 1858 Toole joined Webster at the Adelphi, and established his popularity as a comedian, among other parts creating Joe Spriggins in *Ici on parle français*. In 1868 he was engaged at the Gaiety, appearing among other pieces in *Thespis*, the first Gilbert and Sullivan collaboration. His fame was at its height in 1874, when he went on tour to the United States, but he failed to reproduce there the success he had in England. In 1879 he took the "Folly" theatre in London, which he renamed "Toole's" in 1882. He was constantly away in the provinces, but he produced here a number of plays: H. J. Byron's *Upper Crust* and *Auntie*; Pinero's *Hester's Mystery* and *Girls and Boys*; burlesques such as *Paw Claudian*, and, later, J. M. Barrie's *Walker, London*. But his appearances gradually became fewer, and after 1893 he was seen no more on the London stage, while his theatre was pulled down shortly afterwards for an extension of Charing Cross Hospital. He published his reminiscences in 1888. Toole married in 1854; and the death of his only son in 1879, and later of his wife and daughter, had distressing effects on his health; attacks of gout, from 1886 onwards, crippled him, and ultimately he retired to Brighton, where after a long illness he died on the 30th of July 1906. In his prime he was immensely popular, and also immensely funny in a way which depended a good deal on his tricks and delivery of words. He excelled in what may be called Dickens parts—combining humour and pathos. He was a good man of business, and left a considerable fortune, out of which he made a number of bequests to charity and to his friends. His genial and sympathetic nature was no less conspicuous off the stage than on it.

TOOMBS, ROBERT (1810–1885), American political leader, was born near Washington, Wilkes county, Georgia, on the 2nd of July 1810. He was educated at Franklin College (university of Georgia), at Union College, Schenectady, New York, from which he graduated in 1828, and at the law school of the university of Virginia. He was admitted to the bar in 1830, and served in the Georgia House of Representatives (1838, 1840–1841 and 1843–1844), in the Federal House of Representatives (1845–1853), and in the United States Senate (1853–1861). He opposed the annexation of Texas, the Mexican War, President Polk's Oregon policy, and the Walker Tariff of 1846. In common with Alexander H. Stephens and Howell Cobb, he supported the Compromise Measures of 1850, denounced the Nashville Convention, opposed the secessionists in Georgia, and helped to frame the famous Georgia platform (1850). His position and that of Southern Unionists during the decade 1850–1860 has often been misunderstood. They disapproved of secession, not because they considered it wrong in principle, but because they considered it inexpedient. On the dissolution of the Whig party Toombs went over to the Democrats. He favoured the Kansas-Nebraska Bill, the admission of Kansas under the Lecompton Constitution, and the English Bill (1858), and on the 24th of June 1856 introduced in the Senate the Toombs Bill, which proposed a constitutional convention in Kansas under conditions which were acknowledged by various anti-slavery leaders as fair, and which mark the greatest concessions made by the pro-slavery senators during the Kansas struggle. The bill did not provide for the submission of the constitution to popular vote, and the silence on this point of the territorial law under which the Lecompton Constitution of Kansas was framed in 1857 was the crux of the Lecompton struggle (see KANSAS). In the presidential campaign of 1860 he supported John C. Breckinridge, and on the 22nd of December, soon after the election of Lincoln, sent a telegram to Georgia which asserted that "secession by the 4th of March next should be thundered forth from the ballot-box by the united voice of Georgia." He delivered a farewell address in the Senate (Jan. 7, 1861), returned to Georgia, and with Governor Joseph E. Brown led the fight for secession against Stephens and Herschel V. Johnson (1812–1880). His influence was a most powerful factor in inducing the "old-line Whigs" to support immediate secession. After a short term as secretary of state in President Davis's cabinet, he entered the army (July 21, 1861), and served first as a brigadier-general in the Army of Northern Virginia and after 1863 as adjutant and inspector-general of General G. W. Smith's division of Georgia militia. He then spent two years in exile in Cuba, France and England, but returned to Georgia in 1867, and resumed the practice of law. Owing to his refusal to take the oath of allegiance, he was never restored to the full rights of citizenship. He died at his home in Washington, Georgia, on the 15th of December 1885.

See Pleasant A. Stovall, *Robert Toombs, Statesman, Speaker, Soldier, Sage* (New York, 1892).

TOOTHWORT, the popular name for a small British plant of curious form and growth, known botanically as *Lathraea squamaria*. It grows parasitically on roots, chiefly of hazel, in shady places such as hedge sides. It consists of a branched whitish underground stem closely covered with thick fleshy colourless leaves, which are bent over so as to hide the under surface; irregular cavities communicating with the exterior are formed in the thickness of the leaf. On the inner wall of these chambers are stalked hairs, which when stimulated by the touch of an insect send out delicate filaments by means of which the insect is killed and digested. The only portions that appear above ground are the short flower-bearing shoots, which bear a spike of two-lipped dull purple flowers. The scales which represent the leaves also secrete water, which escapes and softens the ground around the plant. *Lathraea* is closely allied to another British parasitic plant, broomrape (*Orobanche*).

TOOWOOMBA, a town of Aubigny county, Queensland, Australia, 76 m. by rail W. by N. of Ipswich, and 101 m. from Brisbane. It is situated on the summit of the Great Dividing Range, and is the centre of the rich pastoral and agricultural district of Darling Downs. The chief buildings are the town-hall, a large theatre, a school of arts and a library; the Christian Brothers College and several handsome churches. The industries are brewing, tanning, soap-boiling, flour-milling, malting, iron-founding, saw-milling and jam-making. Vineyards are cultivated by a German colony and large quantities of wine are made. The town received a municipal charter in 1860, and during the governorship of Lord Lamington (1896–1897) became the summer residence of the governor and his staff. Pop. (1901), 9137; within the five-mile radius, 14,087.

TOP (cf. Dan. *top*, Ger. *Topf*, also meaning pot), a toy consisting of a body of conical, circular or oval shape with a point or peg on which it turns or is made to whirl. The twisting or whirling motion is applied by whipping or lashing when it is a "whipping top" or "peg-top," or by the rapid unwinding of a string tightly wound round a head or handle. When the body is hollow this results in a whirring noise, whence the name "humming top." Other kinds of tops are made as supports for coloured disks which on revolving show a kaleidoscopic variation of patterns. The top is also used in certain games of chance, when it is generally known as a "teetotum." There are many references to it in ancient classical literature. The Greek terms for the toy are βέμβιξ, which was evidently the whipping or peg top (Arist. *Birds*, 1461), and στρόβιλος, a humming top, spun by a string (Plato, *Rep.* iv. 436 E.). In Homer (*Il.* xiv. 413) the word *στρόμβος* seems to point to the humming top. The Latin name for the top was *turbo*. This word and the Greek *ῥόμβος* are sometimes translated by "top" when they refer to the instrument used in the Dionysiac mysteries, which, when whirled in the air by a string, produced a booming noise. This was no doubt the equivalent of the "bull roarer" (*q.v.*). Strutt (*Games and Pastimes*, 491) says that the top was known in England as early as the 14th century. For the scientific properties of the top see GYROSCOPE and GYROSTAT.

This word must be distinguished from that signifying the highest or uppermost part of anything. It appears to have meant originally a tuft or crest of hair, cf. Ger. *Zopf*, Du. *top*, Icel. *topps*, &c.; it is allied to Eng. "tap," a spike for a cask, and "tip," point. Some etymologists have identified the two words, the toy being so called from spinning on its top or tip, but the two German forms seem to prove conclusively that the words are different.

TOPAZ, a mineral usually found in connexion with granitic rocks and used, when fine, as a gem-stone. It is believed that the topaz of modern mineralogists was unknown to the ancients, and that the stone described under the name of *τοπάζιος*, in allusion to its occurrence on an island in the Red Sea known as *τοπάζιος νῆσος*, was the mineral which is now termed chrysolite or peridot (*q.v.*). The Hebrew *pitdah*, translated "topaz" in the Old Testament, may also have been the chrysolite.

Topaz crystallizes in the orthorhombic system, usually with a prismatic habit (figs. 1 and 2). Many of the crystals, like those from Saxony and Siberia, are rich in faces, and present with the prisms a complicated combination of pyramids and domes. The faces of the prism-zone are usually striated vertically. Doubly-terminated crystals are rare, and sometimes apparently hemimorphic. The mineral presents a perfect cleavage transverse

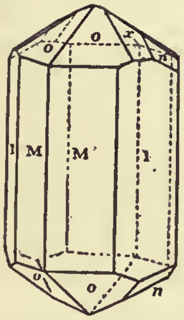

FIG. 1.

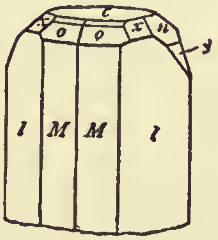

FIG. 2.

to the long axis of the prism, and the cleavage-plane often has a pearly lustre. The chemical composition of the topaz has given rise to much discussion, but it is now generally regarded as an aluminium fluo-silicate having the formula $Al_2F_2SiO_4$. It was shown by Professor S. L. Penfield and Mr J. C. Minor that the fluorine may be partially replaced by hydroxyl. When strongly heated topaz suffers considerable loss of weight. Sir D. Brewster found in topaz numerous microscopic cavities containing fluids, some of which have received the names of brewsterlinite and cryptolinite. Possibly some of the liquid inclusions may be hydrocarbons.

The topaz, when pure, may be colourless, and if cut as a brilliant has been mistaken for diamond. It has, too, the same specific gravity, about 3·5. It is, however, greatly inferior in hardness, the hardness of topaz being only 8; and it has lower refractivity and dispersive powers: moreover, being an orthorhombic mineral, it possesses double refraction. From phenacite and from rock-crystal, for which it may be mistaken, it is distinguished by being biaxial and by having a much higher specific gravity. The topaz becomes electric by heating, by friction or by pressure. Colourless limpid topazes are known in Brazil as *pingos d'agoa*, or "drops of water," whilst in England they pass in trade as "minas novas," from a locality in the state of Minas Geraes in Brazil.

Coloured topazes usually present various shades of yellow, blue or brown. The pleochroism is fairly marked, the colour of the sherry-yellow crystals from Brazil being generally resolved by the dichroscope into a brownish-yellow and a rose-pink. The colour in many cases is unstable, and the brown topazes of Siberia are specially liable to suffer bleaching by exposure to sunlight. In 1750 a Parisian jeweller named Dumelle discovered that the yellow Brazilian topaz becomes pink on exposure to a moderate heat, and this treatment has since been extensively applied, so that nearly all the pink topaz occurring in jewelry has been artificially heated. Such "burnt topaz" is often known as "Brazilian ruby," a name applied also to the natural red topaz, which, however, is excessively rare. "Brazilian sapphire" is the term sometimes given to blue topaz, but the colour is usually pale. The delicate green topaz has been incorrectly called aquamarine, which is a name applicable only to the sea-green beryl (*q.v.*). According to A. K. Coomáraswámy, yellow sapphire is often sold as topaz in Ceylon, where yellow topaz is unknown, whilst pink corundum is frequently called there "king topaz."

The topaz is cut on a leaden wheel, and polished with tripoli. It is generally step-cut, or table-cut, but its beauty is best developed when in the form of a brilliant. Cut topazes of large size are known, and it is said that the great "Braganza diamond" of Portugal is probably a topaz.

Topaz usually occurs in granitic and gneissose rocks, often in greisen, and is commonly associated with cassiterite, tourmaline and beryl. It seems to have been formed, in many cases, by pneumatolytic action. In the west of England it is found in Cornwall, notably at St Michael's Mount and at Cligga Head near St Agnes. It occurs also in Lundy Island. The finest British topaz is found in the Cairngorm group of mountains in the central Highlands, especially at Ben a Buird. Rolled pebbles occur in the bed of the Avon in Banffshire. Beautiful, though small, crystals occur in the drusy cavities of the granite of the Mourne Mountains in Ireland. The famous topaz-rock of the Schneckenstein, near Auerbach, in Saxony, yields pale yellow crystals, formerly cut for jewelry, and it is said that these do not become pink on heating. Fine topazes occur in Russia, at several localities in the Urals and in the Adun-chalon Mountains, near Nerchinsk, in Siberia. A very fine series from the Koksharov collection is in the British Museum. Beautiful crystals of topaz are found in Japan, especially at Takayama in the province of Mino, and at Tanokamiyama in Omi province. Ceylon and Burma occasionally yield topazes. Brazil is a famous locality, the well-known sherry-yellow crystals coming from Ouro Preto, formerly called Villa Rica, the capital of Minas Geraes, where they occur in a kaolinitic matrix, resulting from the alteration of a mica-schist, which is regarded by Professor O. A. Derby as a metamorphosed igneous rock. Topaz occurs in the tin-drifts of New South Wales, especially in the New England district; it has been discovered in the Coolgardie goldfield, West Australia; and it is found also in the tinfields of Tasmania and on Flinders Island in Bass's Strait. Fine topaz has been worked near Pike's Peak in Colorado, and in San Diego county, California. The mineral occurs in rhyolite at Nathrop in Chaffee county and Chalk Mountain in Summit county, Colorado, and in trachyte near Sevier Lake, Utah. The occurrence of topaz in these volcanic rocks is very notable, and contrasts with its common occurrence in granites. It is found in like manner in rhyolite at San Luis Potosi in Mexico; and beautiful little limpid crystals accompany stream-tin at Durango. Common topaz occurs in coarse crystals at many localities. A columnar variety from the tin-districts of Saxony and Bohemia, and from Mt Bischoff in Tasmania, is known as pycnite (*πυκνός*, dense); whilst a coarse opaque topaz from granite near Falun, in Sweden, has been termed pyrophysalite (*πῦρ*, fire; *φυσάω*, to blow), in allusion to its behaviour when heated.

"Oriental topaz" is the name sometimes given to yellow corundum, a mineral readily distinguished from true topaz by superior hardness and density. Yellow and smoke-tinted quartz, or cairngorm, is often known as "Scotch topaz" or "Spanish topaz," according to its locality; but these, on the contrary, are inferior in hardness and density. The chief differences between the three minerals may be seen in the following table, in which they are arranged in order of hardness, density and refractivity:—

	Scotch Topaz.	True Topaz.	Oriental Topaz.
Hardness	7	8	9
Specific gravity	2·6	3·5	4
Refractive indices	1·54, 1·55	1·61, 1·62	1·76, 1·77
Crystallization	Hexagonal	Orthorhombic	Hexagonal
Chemical composition	SiO_2	$Al_2F_2SiO_4$	Al_2O_3

(F. W. R.*)

TOPEKA, a city and the county-seat of Shawnee county, Kansas, U.S.A., the capital of the state, situated on both sides of the Kansas river, in the east part of the state, about 60 m. W. of Kansas City. Pop. (1900), 33,608, of whom 3201 were foreign-born (including 702 Germans, 575 Swedes, 512 English, 407 Russians, 320 Irish, &c.) and 4807 were negroes; (1910, census), 43,684. It is served by the Atchison, Topeka & Santa Fé, the Chicago, Rock Island & Pacific, the Union Pacific and the Missouri Pacific railways. The city is regularly laid out on a fairly level prairie bench, considerably elevated above the river and about 890 ft. above sea-level. Among its prominent buildings are the United States government building, the Capitol (erected 1866–1903 at a cost of $3,200,589 and one of the best state buildings in the country), the county court house, the public library (1882), an auditorium (with a seating capacity of about 5000), the Y.M.C.A. building, a memorial building, housing historical relics of the state, and Grace Church Cathedral (Protestant Episcopal). The city is the see of a Protestant Episcopal bishop. In the Capitol are the library (about 6000 volumes) and natural history collections of the Kansas Academy of Science, and the library (30,000 books, 94,000 pamphlets and 28,500 manuscripts) and collections of the Kansas State Historical Society, which publishes *Kansas Historical Collections* (1875 sqq.) and *Biennial Reports* (1879 sqq.). The city is the seat of Washburn (formerly Lincoln) College (1865), which took its present name in 1868 in honour of Ichabod Washburn of Worcester, Massachusetts, who gave it $25,000; in 1909 it had 783 students (424 being women). Other educational establishments are the College of the Sisters of Bethany (Protestant Episcopal, 1861), for women, and the Topeka Industrial and Educational Institute (1895), for negroes. In Topeka are the state insane asylum, Christ's Hospital (1894), the Jane C. Stormont Hospital and Training School for nurses (1895), the Santa Fé Railway Hospital, the Bethesda Hospital (1906) and the St Francis Hospital (1909). Topeka is an important manufacturing city. Its factory product was valued in 1905 at $14,448,869. Natural gas is piped from southern Kansas for manufacturing and domestic use.

The first white settlement on the site of Topeka was made in 1852, but the city really originated in 1854, when its site was chosen by a party from Lawrence. It was from the first a free-state stronghold. More than one convention was held here in Territorial days, including that which framed the Topeka Constitution of 1855; and some of the meetings of the free-state legislature chosen under that document (see KANSAS) were also held here. Topeka was made the temporary state capital under the Wyandotte Constitution, and became the permanent capital in 1861. It was first chartered by the pro-slavery Territorial legislature in 1857, but did not organize its government until 1858 (see LAWRENCE). In 1881 it was chartered as a city of the first class. The first railway outlet, the Union Pacific, reached Eugene, now North Topeka, in 1865. The construction of the Atchison, Topeka & Santa Fé was begun here in 1868, and its construction shops, of extreme importance to the city, were built here in 1878. In 1880, just after the great negro immigration to Kansas, the coloured population was 31% of the total.

See F. W. Giles, *Thirty Years in Topeka* (Topeka, 1886).

TOPELIUS, ZAKRIS [ZACHARIAS] (1818–1898), Finnish author, was born at Kuddnäs, near Nykarleby, on the 14th of January 1818. He was the son of a doctor of the same name, who was distinguished as the earliest collector of Finnish folk-songs. Topelius became a student at Helsingfors in 1833, was made professor in 1863 and received in succession all the academic distinctions open to him. Quite early in his career he began to distinguish himself as a lyric poet, with the three successive volumes of his *Heather Blossoms* (1845–1854). The earliest of his historical romances was *The Duchess of Finland*, published in 1850. He was also editor-in-chief of the *Helsingfors Gazette* from 1841 to 1860. In 1878 Topelius was allowed to withdraw from his professional duties, but this did not sever his connexion with the university; it gave him, however, more leisure for his abundant and various literary enterprises. Of all the multifarious writings of Topelius, in prose and verse, that which has enjoyed the greatest popularity is his *Tales of a Barber-Surgeon*, episodes of historical fiction from the days of Gustavus II. Adolphus to those of Gustavus III., treated in the manner of Sir Walter Scott; the five volumes of this work appeared at intervals between 1853 and 1867. Topelius attempted the drama also, with most success in his tragedy of *Regina von Emmeritz* (1854). Topelius aimed, with eminent but perhaps pathetic success, at the cultivation of a strong passion of patriotism in Finland. He died on the 13th of March 1898 at Helsingfors. Topelius was an exceptionally happy writer for children, his best-known book being *Läsning för barn*. His abundant poetry is graceful and patriotic, but does not offer any features of great originality. (E. G.)

TOPETE, JUAN BAUPTISTA (1821–1885), Spanish naval commander and politician, was born in Mexico on the 24th of May 1821. His father and grandfather were also Spanish admirals. He entered the navy at the age of seventeen, cut out a Carlist vessel in 1839, became a midshipman at twenty-two, obtained the cross of naval merit for saving the life of a sailor in 1841 and became a lieutenant in 1845. He served on the West Indian station for three years, and was engaged in repressing the slave trade before he was promoted frigate captain in 1857. He was chief of staff to the fleet during the Morocco War, 1859, after which he got the crosses of San Fernando and San Hermenegildo. Having been appointed chief of the Carrara arsenal at Cadiz, he was elected deputy and joined the Union Liberal of O'Donnell and Serrano. He was sent out to the Pacific in command of the frigate "Blanca," and was present at the bombardment of Valparaiso and Callao, where he was badly wounded, and in other engagements of the war between Chile and Peru. On his return to Spain, Topete was made port captain at Cadiz, which enabled him to take the lead of the conspiracy in the fleet against the Bourbon monarchy. He sent the steamer "Buenaventura" to the Canary Isle for Serrano and the other exiles; and when Prim and Sagasta arrived from Gibraltar, the whole fleet under the influence of Topete took such an attitude that the people, garrison and authorities of Cadiz followed suit. Topete took part in all the acts of the revolutionary government, accepted the post of marine minister, was elected a member of the Cortes of 1869, supported the pretensions of Montpensier, opposed the election of Amadeus, sat in several cabinets of that king's reign, was prosecuted by the federal republic of 1873 and again took charge of the marine under Serrano in 1874. After the Restoration Topete for some years held aloof, but finally accepted the presidency of a naval board in 1877, and sat in the Senate as a life peer until his death on the 29th of October 1885 at Madrid.

TÖPFFER, RODOLPHE (1799–1846), the inventor of pedestrian journeys in Switzerland by schoolboys, was born at Geneva on the 31st of January 1799. His grandfather, a tailor, came about 1760 from Schweinfurt (Bavaria) to settle in Geneva, while his father, Adam, was an artist. Rodolphe's literary education was rather desultory, as he intended to be an artist, like his father. But in 1819 his weak eyesight put an end to that intention, so he studied in Paris, intending to devote himself to the profession of schoolmaster. After passing some time in a private school in Geneva (1822–1824), he founded (1824) one of his own, after his marriage. It was in 1823 that he made his first foot journey in the Alps with his pupils, though this became his regular practice only from 1832 onwards. These *Voyages en zigzag* were described annually (1832–1843) in a series of lithographed volumes, with sketches by the author—the first printed edition appeared at Paris in 1844, and a second series (*Nouveaux voyages en zigzag*) also at Paris in 1854. Both series have since passed through many editions. In 1832 he was named professor of belles-lettres at the university of Geneva, and held that chair till his death, on the 8th of June 1846. As early as 1830 he published an article in the *Bibliothèque universelle* of Geneva. It was followed by a number of tales, commencing with the *Bibliothèque de mon oncle* (1832), many of which were later collected (1841) into the well-known volume which bears the title of *Nouvelles genevoises*. He took some part (on the Conservative side) in local politics, and was (1841–1843) editor of the *Courrier de Genève*. Among his other works are an edition of Demosthenes (1824), and a volume of artistic studies, the *Réflexions et menus propos d'un peintre génevois* (1848).

Lives by A. Blondel and the abbé Relave (both published at Paris, 1886), and shorter notices in E. Rambert's *Écrivains nationaux* (Geneva, 1874); and E. Javelle's *Souvenirs d'un alpiniste* (Lausanne, 1886; Eng. trans., 1899, under the title of *Alpine Memories*), and several chapters in Ste Beuve's *Causeries du lundi, Derniers portraits littéraires* and *Portraits contemporains*. (W. A. B. C.)

TOPHET, or Topheth (תֹּפֶת), the name given in 2 Kings xxiii. 10; Jer. vii. 31, to a spot in the valley of Ben Hinnom near Jerusalem where the Hebrews in the time of Ahab and Manasseh offered children to Molech and other heathen gods. Josiah "defiled" it as part of his reforming activity, and it became a place for the bestowal and destruction of refuse, and a synonym for Gehenna (Isa. xxx. 33; Jer. vii. 32).

The uncertain etymology of the word is discussed in the *Ency. Bib., s.v.* "Molech," § 3, "Topheth."

TOPIARY, a term in gardening or horticulture for the cutting and trimming of shrubs, such as cypress, box or yew, into regular and ornamental shapes. It is usually applied to the cutting of trees into urns, vases, birds and other fantastic shapes, which were common at the end of the 17th century and through the 18th, but it also embraces the more restrained art necessary for the laying out of a formal garden. Yew and holly trees cut into fantastic objects may still be seen in old-fashioned cottage or farmhouse gardens in England. The Lat. *topiarius* meant an ornamental or landscape gardener, and was formed from *topia* (Gr. τόπος, place), a term specially employed for a formal kind of landscape painting used as a mural decoration in Roman houses.

TOPLADY, AUGUSTUS MONTAGUE (1740–1778), Anglican divine, was born at Farnham, Surrey, and educated at Westminster and Trinity College, Dublin. Although originally a follower of Wesley, he in 1758 adopted extreme Calvinist opinions. He was ordained in 1762 and became vicar of Harpford with Fenn-Ottery, Devonshire, in 1766. In 1768 he exchanged to the living of Broadhembury, Devonshire. He is chiefly known as a writer of hymns and poems, including "Rock of Ages," and the collections entitled *Poems on Sacred Subjects* (Dublin, 1759) and *Psalms and Hymns for Public and Private Worship* (London, 1776). His best prose work is the *Historic Proof of the Doctrinal Calvinism of the Church of England* (London, 1774). Some comments by Wesley upon Toplady's presentation of Calvinism led to a controversy which was carried on with much bitterness on both sides. Toplady wrote a venomous *Letter to Mr Wesley* (1770), and Wesley repeated his comments in *The Consequence Proved* (1771), whereupon Toplady replied with increased acridity in *More Work for Mr Wesley* (1772). From 1775 to 1778, having obtained leave of non-residence at Broadhembury, he lived in London, and ministered at a Calvinist church in Orange Street.

TOPOGRAPHY (Gr. τόπος, place, γράφειν, to write), a description of a town, district or locality, giving details of its geographical and architectural features. The term is also applied in anatomy to the mapping out of the surface of the human body, either according to a division based on the organs or parts lying below certain regions, or on a superficial plotting out of the body by anatomical boundaries and landmarks.

TORAN, the name in Hindustani (Skr.. *torana*, from *tor*, pass) of a sacred or honorific gateway in Buddhist architecture. Its typical form is a projecting cross-piece resting on two uprights or posts. It is made of wood or stone, and the cross-piece is generally of three bars placed one on the top of the other; both cross-piece and posts are usually sculptured.

TORBERNITE (or cupro-uranite), a mineral which is one of the "uranium micas"; a hydrous uranium and copper phosphate, $Cu(UO_2)_2(PO_4)_2+12H_2O$. Crystals are tetragonal and have the form of square plates, which are often very thin. There is a perfect micaceous cleavage parallel to the basal plane, and on this face the lustre is pearly. The bright grass-green colour is a characteristic feature of the mineral. The hardness is $2\frac{1}{2}$ and the specific gravity 3·5. The radio-activity of the mineral is greater than that of some specimens of pitchblende. It was first observed in 1772 at Johanngeorgenstadt in Saxony, but the best examples are from Gunnislake near Calstock and Redruth in Cornwall. The name torbenite is after Torbern Bergman: *chalcolite* is a synonym. (L. J. S.)

TORCELLO, an island of Venetia, Italy, in the lagoons about 6 m. to the N.W. of Venice, belonging to the commune of Burano. It was a flourishing city in the early middle ages, but now has only a few houses and two interesting churches. The former cathedral of S. Maria was founded in the 7th century. The present building, a basilica with columns, dates from 864; the nave was restored in 1008, in which year the now ruined octagonal baptistery was built. It contains large mosaics of the 12th century, strongly under Byzantine influence; those on the west wall represent the Resurrection and Last Judgment. The seats for the priests are arranged round the semicircular apse, rising in steps with the bishop's throne in the centre—an arrangement unique in Italy. Close by is S. Fosca, a church of the 12th century, octagonal outside, with colonnades on five sides and a rectangular interior intended for a dome which was never executed, beyond which is a three-apsed choir. In the local museum are four Mycenaean vases, one found in the island and another on the adjacent island of Mazzorbo, proving direct intercourse with the Aegean Sea in prehistoric times.

See R. M. Dawkins, in *Journal of Hellenic Studies* (1904), xxiv. 125.

TORCH (O. Fr. *torche*, from Med. Lat. *tortia*, derived from *tortus*, twisted, *torquere*, to twist), a light or illuminant that can be carried in the hand, made of twisted tow, hemp or other inflammable substance. Torches or "links" were, till the general introduction of street lighting, necessary adjuncts for passengers on foot or in carriages in towns at night, and many of the older houses in London and elsewhere still retain the iron stands outside their doors, in which the torches might be placed.

TORCHÈRE, a candelabrum mounted upon a tall stand of wood or metal, usually with two or three lights. When it was first introduced in France towards the end of the 17th century the torchère mounted one candle only, and when the number was doubled or tripled the improvement was regarded almost as a revolution in the lighting of large rooms.

TORDENSKJOLD, PEDER (1691–1720), eminent Danish naval hero, the tenth child of alderman Jan Wessel of Bergen, in Norway, was born at Trondhjem on the 28th of October 1691. Wessel was a wild unruly lad who gave his pious parents much trouble. Finally he ran away from them by hiding in a ship bound for Copenhagen, where the king's chaplain Dr Peder Jespersen took pity on the friendless lad, gratified his love for the sea by sending him on a voyage to the West Indies, and finally procured him a vacant cadetship. After further voyages, this time to the East Indies, Wessel was, on the 7th of July 1711, appointed 2nd lieutenant in the royal marine and shortly afterwards became the captain of a little 4-gun sloop "Ormen" (The Serpent), in which he cruised about the Swedish coast and picked up much useful information about the enemy. In June 1712 he was promoted to a 20-gun frigate, against the advice of the Danish admiralty, which pronounced him to be too flighty and unstable for such a command. His discriminating patron was the Norwegian admiral Lövendal, who was the first to recognize the young man's ability as a naval officer. At this period Wessel was already renowned for two things: the audacity with which he attacked any Swedish vessels he came across regardless of odds, and his unique seamanship, which always enabled him to escape capture. The Great Northern War had now entered upon its later stage, when Sweden, beset on every side by foes, employed her fleet principally to transport troops and stores to her distressed German provinces. The audacity of Wessel impeded her at every point. He was continually snapping up transports, dashing into the fjords where her vessels lay concealed, and holding up her detached frigates. In July 1714 he encountered a frigate which had been equipped in England for the Swedes and was on its way to Gothenburg under the command of an English captain. Wessel instantly attacked her but in the English captain he met his match. The combat lasted all day, was interrupted by nightfall, and renewed again indecisively the following morning. Wessel's free and easy ways procured him many enemies in the Danish navy. He was accused of unnecessarily endangering his majesty's war-ships in the affairs with the frigate and he was brought before a court-martial. But the spirit with which he defended himself and the contempt he poured on his less courageous comrades took the fancy of King Frederick IV., who cancelled the proceedings and raised Wessel to the rank of captain. When in the course of 1715 the return of Charles XII. from Turkey to Stralsund put a new life into the jaded and dispirited Swedish forces, Wessel distinguished himself in numerous engagements off the Pomeranian coast and did the enemy infinite damage by cutting out their frigates and destroying their transports. On returning to Denmark in the beginning of 1716 he was ennobled under the title of "Tordenskjold" (Thundershield). When in the course of 1716 Charles XII. invaded Norway and sat down before the fortress of Fredrikshald, Tordenskjold compelled him to raise the siege and retire to Sweden by pouncing upon the Swedish transport fleet laden with ammunition and other military stores which rode at anchor in the narrow and dangerous strait of Dynekil, utterly destroying the Swedish fleet with little damage to himself. For this, his greatest exploit, he was promoted to the rank of commander, but at the same time incurred the enmity of his superior officer Admiral Gabel, whom he had omitted to take into his confidence on the occasion. Tordenskjold's first important command was the squadron with which he was entrusted in the beginning of 1717 for the purpose of destroying the Swedish Gothenburg squadron which interrupted the communications between Denmark and Norway. Owing to the disloyalty of certain of his officers who resented serving under the young adventurer, Tordenskjold failed to do all that was expected of him. His enemies were not slow to take advantage of his partial failure. The old charge of criminal recklessness was revived against him at a second court-martial before which he was summoned in 1718; but his old patron Admiral U. C. Gyldenlöve again intervened energetically in his behalf and the charge was quashed. In December 1718 Tordenskjold brought to Frederick IV. the welcome news of the death of Charles XII. and was made a rear-admiral for his pains. Tordenskjold's last feat of arms was his capture of the Swedish fortress of Marstrand, when he partially destroyed and partially captured the Gothenburg squadron which had so long eluded him. He was rewarded with the rank of vice-admiral. Tordenskjold did not long survive the termination of the war. On the 20th of November 1720 he was killed in a duel with a Livonian colonel, Jakob Axel Stael von Holstein. Although, Dynekil excepted, Tordenskjold's victories were of far less importance than Sehested's at Stralsund and Gyldenlöve's at Rügen, he is certainly, after Charles XII., the most heroic figure of the Great Northern War. His courage was fully equal to the courage of "The Lion of the North," but he lacked that absolute self-command which gives to the bravery of Charles XII. its peculiar, almost superhuman, character.

See Carstensen and Lütken, *Tordenskjold* (Copenhagen, 1887).
(R. N. B.)

TOREADOR, a Spanish word derived from *torear*, to engage in a bull-fight, *toro*, a bull, Latin *taurus*, for one of the principal performers in the national sport of bull-fighting (*q.v.*).

TORELL, OTTO MARTIN (1828–1900), Swedish geologist, was born in Varberg on the 5th of June 1828. He was educated at Lund for the medical profession, but became interested in zoological and geological studies, and being of independent means he devoted himself to science. He gave his attention first especially to the invertebrate fauna and the physical changes of pleistocene and recent times. He studied the glacial phenomena of Switzerland, Spitzbergen and Greenland, making two Arctic expeditions in company with A. E. Nordenskiöld. In 1866 he became professor of zoology and geology in the University at Lund, and in 1871 he was appointed chief of the Swedish Geological Survey. In the latter capacity he laboured until 1897. His published contributions, though of much interest and importance, were not large, but his influence in promoting a knowledge of geology in Sweden was of great service. His Arctic experiences enabled him to interpret the method of origin of the drift deposits in northern Europe, and to show that they were largely of glacial or fluvio-glacial origin. In the English drifts he recognized many boulders of Scandinavian origin. He died on the 11th of September 1900.

His publications include: *Bidrag till Spitzbergens molluskfauna* (1859); and memoirs to accompany several sheets of the Geological Survey map of Sweden.

Obituary with portrait, in *Geol. Mag* (May 1902), reproduced in abridged form from memoir by L. Holmström, in *Geologiska foreningen i Stockholm's forhandlingar*, xxiii.

TORENO, JOSÉ MARIA QUIEPO DE LLANO RUIZ DE SARAVIA, Count of (1786–1843), Spanish politician and historian, was born at Oviedo on the 25th of November 1786. His family was wealthy and belonged to the most ancient nobility of Asturias. His mother, Dominga Ruiz de Saravia, had property in the province of Cuenca. The son received a better education in classics, mathematics and modern languages than was usual at that time. The young viscount of Matarrosa, the title he bore in his father's lifetime, was introduced to the writings of Voltaire and Rousseau by the abbot of the Benedictine house of Monserrat in Madrid. He was present at Madrid when the city rose against Murat on the 2nd of May 1808, and took part in the struggle which was the beginning of the Peninsular War. From Madrid he escaped to Asturias, and on the 30th of May he embarked in a Jersey privateer at Gijon, with other delegates, in order to ask for the help of England against the French. The deputation was enthusiastically received in London. By the 30th of December he was back in Asturias, his father having died in the interval. During the Peninsular War he saw some service in the first occupation of Asturias by the French, but he was mainly occupied by his duties as a member of the Cortes. In 1809 he was at Seville, where one of his uncles was a member of the central Junta. In the following year he was a leader of the party which compelled the Regency to summon the Cortes—to which he was elected by Asturias early in 1811 though he wanted some months of the legal age of twenty-five. His election was opposed by some of his own relatives who did not share his advanced opinions, but it was ratified by the Cortes. Toreno was conspicuous among the well-meaning men who framed the constitution of 1812, which was made as if it was meant for some imaginary republic and not for Catholic and monarchical Spain. When Ferdinand VII. returned from prison in France in 1814 Toreno foresaw a reaction, and put himself out of reach of the king. He was the more an object of suspicion because his brother-in-law, Porlier, perished in a wild attempt to support the constitution by force. Toreno remained in exile till the outbreak of the revolution of 1820. Between that year and 1823 he was in Spain serving in the restored Cortes, and experience had abated his radical ardour. When the French intervened in 1823 Toreno had again to go into exile, and remained abroad till the king published the amnesty of the 15th of October 1832. He returned home in July 1833, but remained on his estates till the king's death on the 29th of September. As hereditary standard bearer of Asturias (Alferez Mayor) it fell to him to proclaim the young queen, Isabella II. In 1834 his now moderate opinions pointed him out to the queen regent, Maria Christina, as a useful man for office. In June 1834 he was minister of finance, and became prime minister on the 7th of June. His tenure of the premiership lasted only till the 14th of September of the same year, when the regent's attempt to retain a practically despotic government under a thin constitutional veil broke down. The greater part of the remainder of his life was spent in voluntary exile, and he died in Paris on the 16th of September 1843. As a politician he felt the need for a revision of the worn out despotism which ruled till 1808, but he was destitute of any real political capacity. Toreno is chiefly remembered as the author of the *History of the Rising, War* *and Revolution of Spain*, which he began between 1823 and 1832 and published in 1836–1838 in Paris. As a work of military criticism it is not of high value, and Toreno was prejudiced in favour of his colleagues of the Cortes, whose errors and excesses he shared in and excused. The book is, however, written in excellent Castilian, and was compiled with industry. It is worth consulting as an illustration of the time in which the author lived, as a patriotic Spanish view of the war, and for the prominence it gives to the political side of the Peninsular War, which he justly treated as a revolution.

A biography by Don Antonio de Cueto is prefixed to the reprint of the *Levantamiento guerra y revolución de España*, in vol. lxiv. of the *Biblioteca de autores españoles* of Rivadeneyra (Madrid 1846–1880).

TORENO, QUEIPO DE LLANO Y GAYOSO DE, Count (1840–1890), Spanish politician, son of the preceding, was born in Madrid in 1840. He was educated at the Madrid Institute and University, entered parliament in 1864 as a Moderado, and sat in all the Cortes of Queen Isabella's reign as a deputy for his ancestral province, Asturias. Loyal to the Bourbons all through the revolution, he nevertheless became a deputy in the Cortes of 1871–1873, and founded an Alphonsist paper, *El Tiempo*, in 1873. When the Restoration took place, its first cabinet made Count de Toreno mayor of the capital, and in 1875 minister of public works, in which capacity he improved the public libraries, museums, academies and archives, and caused many important works to be published, including the *Cartas de Indias*. In 1879 he became minister for foreign affairs, in 1880 president of the House of Deputies, in 1884 again governor of Madrid, and in 1885 again president of the House of Deputies. During the reign of Alphonso XII. and the first years of the regency of Queen Christina Count de Toreno was one of the most prominent Conservative leaders, and was often consulted by the Crown. He died on the 31st of January 1890. He was a patron of the turf, and established a race-course in Madrid, where the first races took place in the reign of Alphonso XII.

TORGAU, a town of Germany, in the Prussian province of Saxony, situated on the left bank of the Elbe, 30 m. N.E. of Leipzig and 26 m. S.E. of Wittenberg by rail. Pop. (1905), 12,299. Its most conspicuous building is the Schloss Hartenfels, on an island in the Elbe, which was built, or at least was finished, by the elector of Saxony, John Frederick the Magnanimous. This castle, which is now used as a barracks, is one of the largest Renaissance buildings in Germany. It was for some time the residence of the electors of Saxony and contains a chapel consecrated by Martin Luther. The town hall, a 16th-century building, houses a collection of Saxon antiquities. Torgau has two Evangelical churches and a Roman Catholic church. One of the former, the Stadt Kirche, contains paintings by Lucas Cranach and the tomb of Catherine von Bora, the wife of Luther. The chief industries of the town are the manufacture of gloves, carriages, agricultural machinery, beer and bricks; there is a trade in grain both on the Elbe and by rail. The fortifications, begun in 1807 by order of Napoleon, were dismantled in 1889–1891. In the vicinity is the royal stud farm of Graditz.

Torgau is said to have existed as the capital of a distinct principality in the time of the German king Henry I., but early in the 14th century it was in the possession of the margraves of Meissen and later of the electors of Saxony, who frequently resided here. The town came into prominence at the time of the Reformation. In 1526 John, elector of Saxony, Philip, landgrave of Hesse, and other Protestant princes formed a league against the Roman Catholics, and the Torgau articles, drawn up here by Luther and his friends in 1530, were the basis of the confession of Augsburg. Torgau is particularly celebrated as the scene of a battle fought on the 3rd of November 1760, when Frederick the Great defeated the Austrians (see SEVEN YEARS' WAR). In January 1814 Torgau was taken by the Germans after a siege of three months and it was formally ceded to Prussia in 1815.

See Grulich and Bürger, *Denkwürdigkeiten der altsächsischen Residenz Torgau aus der Zeit der Reformation* (Torgau, 1855); Knabe, *Geschichte der Stadt Torgau bis zur Reformation* (Torgau, 1880); and the publications of the *Altertumverein zu Torgau* (Torgau, 1884 sqq.).

TORNADO (Span., *tornada*, a turning about, cf. "turn"), a local whirlwind of extreme violence, usually formed within a thunderstorm. In appearance it consists of a funnel-shaped cloud, depending from the mass of storm-cloud above, and when fully developed tapering downwards to the earth. Besides its whirling motion, a tornado has an advancing movement of from 20 to 40 m. an hour—and along its own narrow path it carries destruction. Its duration is usually from half an hour to an hour. Tornadoes are most common in America, especially in the Mississippi Valley and the Southern states; in Europe and elsewhere they are comparatively rare. Owing to their association with thunderstorms they generally occur in warm weather. A tornado is the result of a condition of local instability in the atmosphere, originating high above the earth. A current of air is induced to ascend with a rapid spiral motion round a central core of low pressure. The moisture in the ascending air is condensed by cooling both as it ascends and as it expands into the low-pressure core. The cloud-funnel appears to grow downwards because the moisture in the air is condensed more rapidly than the air itself, following a spiral course, ascends.

TORO, a town of Spain, in the province of Zamora, on the right bank of the river Duero (Douro), and on the Zamora-Medina del Campo railway. Pop. (1900), 8379. Toro is an ancient fortified town, with picturesque narrow streets, among which are many medieval churches, convents and palaces, besides modern schools and public buildings. A fine bridge of twenty-two arches spans the river. The cathedral church is Romanesque; it dates from the 12th century but has been partially restored. The palace of the marquesses of Santa Cruz was the meeting place of the Cortes of 1371, 1442 and 1505, which made Toro and its code of laws celebrated. Toro is first mentioned in documents of the 10th century. It played an important part in the development of the kingdoms of Leon and Castile and in the reconquest of Spain from the Moors.

TORONTO, the capital of the province of Ontario, and the second largest city in the Dominion of Canada, situated on the northern shore of Lake Ontario, almost due north from the mouth of the Niagara river. It lies on a plateau gradually ascending from the lake shore to an altitude of 220 ft., and covers an area of nearly 20 sq. m. The river Don flows through the eastern part of the city, and the river Humber forms its western limit. The fine bay in front of the city, affording a safe and commodious harbour, is formed by an island stretching along the south of it. The city is well laid out for the most part, the streets crossing each other at right angles; Yonge Street, the chief artery, running north from the bay, was constructed as a military road in 1796, and extends under the same name for upwards of 30 m. to Lake Simcoe. It constitutes the dividing line of the city, the cross streets being called east or west according to the side of it they are on.

Toronto is the seat of government for the province, and contains the parliament buildings, the lieutenant-governor's residence, the courts of law and the educational departmental buildings. The parliament buildings are situated in Queen's Park, almost in the centre of the city, and are an imposing structure of red sandstone in the neo-Greek style built at great cost. They are shortly to be enlarged, as the needs of the province have outgrown them. A little distance to the west stand the university buildings, the central one being a splendid piece of architecture in the Norman style. Stretching in a semicircle round the broad campus are the library, the medical building, the biology building and museum, the school of practical science, the geology and chemistry buildings and the convocation hall, their architecture varying very greatly, beauty having been sacrificed to more practical considerations; the magnetic observatory is also in the grounds, but is overshadowed by some of the more recent erections. It is one of the meteorological stations established by the British government on the recommendation of the Royal Society in 1840 and is now maintained by the Dominion government. The university of Toronto, for the support of which the province is responsible, includes faculties of arts, science and medicine, in the teaching of which it is strictly secular. But near at hand and in full affiliation with the university are Victoria College (Methodist), Wycliffe College (Anglican), Knox College (Presbyterian) and St Michael's College (Roman Catholic), wherein courses in divinity are given and degrees conferred. Victoria College, likewise, provides a course in arts, but none in science. Trinity College (Anglican), though some distance away, is also affiliated with the university, and her students enjoy its full advantages. Besides the university, Toronto is remarkably rich in educational institutions. Upper Canada College, founded in 1829, in many respects resembles one of the English public schools. It has over 300 students. St Andrew's College, also for boys, is a more recent establishment, and has about the same number of pupils. There are three large collegiate institutes, having some 300 to 600 pupils each, and in addition a number of schools for girls, such as Havergal College and Westminster College. Osgoode Hall, a stately structure in the heart of the city, houses the higher courts of law and appeal, and also a flourishing law school. The city hall and court-house is one of the finest civic buildings in North America. It is in the Romanesque style, and accommodates all the civic offices, the board of education, the police and county courts, &c. Many of the churches are worthy examples of good architecture.

Toronto is essentially a residential city. The houses of the better class stand separate, not in long rows, and have about them ample lawns and abundant trees. It is consequently a widespread city, the length from east to west approximating ten miles. An electric railway system provides means of communication. There are many parks, ranging in size from Carlton Park of one acre to High Park (375 acres) and Island Park (389), the latter being across the harbour and constituting the favourite resort of the people during the summer. In Exhibition Park there is held annually an industrial and agricultural exhibition that has grown to great magnitude. It lasts a fortnight in late summer. It is a municipal enterprise and the profits belong to the city.

The population in 1907, as shown by the police census, exceeded 300,000. The government of the city is vested in a council consisting of the mayor and four controllers elected annually and eighteen aldermen (three from each of the six wards into which the city is divided). The council as a whole is the legislative body, while the board of control is the executive body, and as such is responsible for the supervision of all matters of finance, the appointment of officials, the carrying on of public works, and the general administration of the affairs of the city, except the departments of education and of police, the first being under the control of the board of education, elected annually by the citizens, and the latter under the board of police commissioners, consisting of the mayor, the county judge and the police magistrate.

Toronto is one of the chief manufacturing centres of the dominion; agricultural machinery, automobiles, bicycles, cotton goods, engines, furniture, foundry products, flour, smoked meats, tobacco, jewelry, &c., are flourishing industries, and the list is constantly extending. The situation of the city is favourable to commerce, and the largest vessels on the lakes can use its harbour. It is the outlet of a rich and extensive agricultural district, and throughout the season of navigation lines of steamers ply between Toronto and the other lake ports on both the Canadian and American sides, the route of some of them extending from Montreal to Port Arthur on Lake Superior. Railway communication is complete, three great trunk lines making the city a terminal point, viz. the Grand Trunk, the Canadian Pacific and the Canadian Northern.

As a financial centre Toronto has made remarkable advance. The transactions on the stock exchange rival those of Montreal. The Bank of Commerce has its headquarters here, as have also the Bank of Nova Scotia, the Bank of Toronto, the Standard Traders, Imperial, Sovereign, Dominion, Crown, United Empire, Sterling and other banks.

The name of the city is of Indian origin, meaning "a place of meeting," the site in the days before the coming of the white man being an established rendezvous among the neighbouring Indian tribes. It first appears in history in 1749 as a centre of trade when the French built a small fort and started a trading establishment called Fort Rouille. Before long, however, British traders came up from the south and entered into active rivalry with the French, and in 1793 the fort was burned by the latter to prevent its occupation by their foes. A year later Governor Simcoe transferred the seat of government of the new province of Upper Canada from the town of Newark at the mouth of the Niagara River to Toronto, giving the new capital the name of York, in honour of the second son of George III. Under its new name it made slow progress as the surrounding country was cleared and settled. The entrance to the harbour was guarded by two blockhouses; provision was made for barracks and garrison stores; buildings were erected for the legislature; and there the members of parliament, summoned by royal proclamation to "meet us in our provincial parliament in our town of York," assembled on the 1st of June 1797. Sixteen years later the population numbered only 456. The town was twice sacked in the war of 1812. General Dearborn captured it at the head of a force of upwards of 2000. On their advance to the outworks of the garrison the magazine of the fort exploded, whether by accident or design, killing many of the invaders. The halls of legislature and other buildings were burnt and the town pillaged. On the restoration of peace the work of creating a capital for Upper Canada had wellnigh to begin anew. The organization of Upper Canada College in 1830, with a staff of teachers nearly all graduates of Cambridge, gave a great impetus to the city and province. In 1834 the population of York numbered fully 10,000; and an act of the provincial legislature conferred on it a charter of incorporation, with a mayor, aldermen and councilmen. Under this charter it was constituted a city with the name of Toronto. Since that time the progress of the city has been rapid and substantial, the population doubling every twenty years. In 1885 the total assessment was $69,000,000; in 1895 $146,000,000 and in 1906 $167,411,000, the rate of taxation being 18½ mills.

TORPEDO. In 1805 Robert Fulton demonstrated a new method of destroying ships by exploding a large charge of gunpowder against the hull under water. No doubt then remained as to the effectiveness of this form of attack when successfully applied; it was the difficulty of getting the torpedo, as it was called, to the required position which for many years retarded its progress as a practical weapon of naval warfare. Attempts were first made to bring the explosive in contact with the vessel by allowing it to drift down to her by the action of tide or current, and afterwards to fix it against her from some form of diving boat, but successive failures led to its restriction for a considerable period to the submarine mine (*q.v.*) in which the explosive is stationary and takes effect only when the ship itself moves over or strikes the charge. Used in this way, it is an excellent deterrent to hostile warships forcing a harbour.

Spar or Outrigger Torpedo.—The limitations attached to the employment of submarine mines, except for coast defence, revived the idea of taking the torpedo to the ship instead of waiting for the latter to gain some exact point which she might very possibly avoid. This first took practical shape in the spar or outrigger torpedo. This consisted of a charge of explosive at the end of a long pole projecting from the bow of a boat, the pole being run out and immersed on arriving near the object. Directly the charge came in contact with the hull of the ship it was exploded by an electric battery in the boat. If the boat was not discovered and disabled while approaching, the chances were favourable to success and escape afterwards. Against a vigilant enemy it was doubtless a forlorn hope, but to brave men the venture offered considerable attractions.

Frequent use of this spar or outrigger torpedo was made during the American Civil War. A notable instance was the destruction of the Confederate ironclad "Albemarle" at the end of October 1864. On this mission Lieut. Cushing took a steam launch equipped with an outrigger torpedo up the Roanoke River, in which lay the "Albemarle." On arriving near the ship Cushing found her surrounded by logs, but pushing his boat over them, he immersed the spar and exploded his charge in contact with the "Albemarle" under a heavy fire. Ship and launch sank together, but the gallant officer jumped overboard, swam away and escaped. Submerged boats were also used for similar service, but usually went to the bottom with their crews. During the war between France and China in 1884 the "Yang Woo" was attacked and destroyed by an outrigger torpedo.

Locomotive Torpedoes.—Though the spar torpedo had scored some successes, it was mainly because the means of defence against it at that time were inefficient. The ship trusted solely to her heavy gun and rifle fire to repel the attack. The noise, smoke, and difficulty of hitting a small object at night with a piece that could probably be discharged but once before the boat arrived, while rifle bullets would not stop its advance, favoured the attack. When a number of small guns and electric lights were added to a ship's equipment, success with an outrigger torpedo became nearly, if not entirely, impossible. Attention was then turned in the direction of giving motion to the torpedo and steering it to the required point by electric wires worked from the shore or from another vessel; or, dispensing with any such connection, of devising a torpedo which would travel under water in a given direction by means of self-contained motive power and machinery. Of the former type are the Lay, Sims-Edison and Brennan torpedoes. The first two—electrically steered by a wire which trails behind the torpedo—have insufficient speed to be of practical value, and are no longer used. The Brennan torpedo, carrying a charge of explosive, travels under water and is propelled by unwinding two drums or reels of fine steel wire within the torpedo. The rotation of these reels is communicated to the propellers, causing the torpedo to advance. The ends of the wires are connected to an engine on shore to give rapid unwinding and increased speed to the torpedo. It is steered by varying the speed of unwinding the two wires. This torpedo was adopted by the British war office for harbour defence and the protection of narrow channels.

Uncontrolled Torpedoes.—The objection of naval officers to have any form of torpedo connected by wire to their ship during an action, impeding her free movement, liable to get entangled in her propellers and perhaps exploding where not desired—disadvantages which led them to discard the Harvey towing torpedo many years ago—has hitherto prevented any navy from adopting a controlled torpedo for its sea-going fleet. The last quarter of the 19th century saw, however, great advances in the equipment of ships with locomotive torpedoes of the uncontrolled type. The Howell may be briefly described, as it has a special feature of some interest. Motive power is provided by causing a heavy steel fly-wheel inside the torpedo to revolve with great velocity. This is effected by a small special engine outside operating on the axle. When sufficiently spun up, the axle of the flywheel is connected with the propeller shafts and screws which drive the torpedo, so that on entering the water it is driven ahead and continues its course until the power stored up in the flywheel is exhausted. Now when a torpedo is discharged into the sea from a ship in motion, it has a tendency to deflect owing to the action of the passing water. The angle of deflexion will vary according to the speed of the ship, and is also affected by other causes, such as the position in the ship from which the torpedo is discharged, and its own angle with the line of keel. Hence arise inaccuracies of shooting; but these do not occur with this torpedo, for the motion of the flywheel, acting as a gyroscope—the principle of which applied to the Whitehead torpedo is described later—keeps this torpedo on a straight course. This advantage, combined with simplicity in construction, induced the American naval authorities at one time to contemplate equipping their fleet with this torpedo, for they had not, up to within a few years ago, adopted any locomotive torpedo. A great improvement in the torpedo devised by Mr Whitehead led them, however, definitely to prefer the latter and to discontinue the further development of the Howell system.

The Whitehead torpedo is a steel fish-shaped body which travels under water at a high rate of speed, being propelled by two screws driven by compressed air. It carries a large charge of explosive which is ignited on the torpedo striking any hard substance, such as the hull of a ship. The body is divided into three parts. The foremost portion or head contains the explosive—usually wet gun-cotton—with dry primer and mechanical igniting arrangement; the centre portion is the air chamber or reservoir, while the remaining part or tail carries the engines, rudders, and propellers besides the apparatus for controlling depth and direction. This portion also gives buoyancy to the torpedo.

When the torpedo is projected from a ship or boat into the water a lever is thrown back, admitting air into the engines causing the propellers to revolve and drive the torpedo ahead. It is desirable that a certain depth under water should be maintained. An explosion on the surface would be deprived of the greater part of its effect, for most of the gas generated would escape into the air. Immersed, the water above confines the liberated gas and compels it to exert all its energy against the bottom of the ship. It is also necessary to correct the tendency to rise that is due to the torpedo getting lighter as the air is used up, for compressed air has an appreciable weight. This is effected by an ingenious apparatus long maintained secret. The general principle is to utilize the pressures due to different depths of water to actuate horizontal rudders, so that the torpedo is automatically directed upwards or downwards as its tendency is to sink or rise.

The efficiency of such a torpedo compared with all previous types was clearly manifest when it was brought before the maritime states by the inventor, Whitehead, and it was almost universally adopted. The principal defect was want of speed—which at first

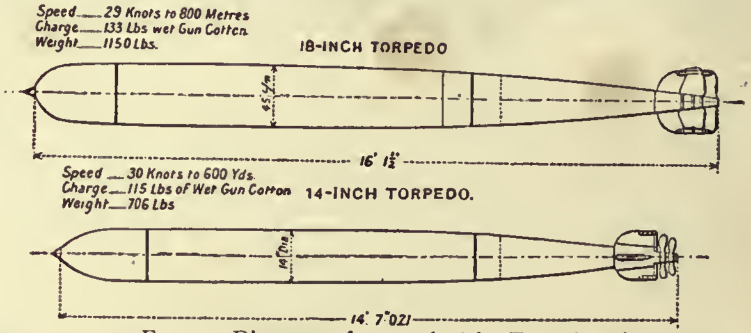

FIG. 1.—Diagrams of 14- and 18-in. Torpedoes.

did not exceed 10 knots an hour—but by the application of Brotherhood's 3-cylinder engine the speed was increased to 18 knots—a great advance. From that time continuous improvements have resulted in speeds of 30 knots and upwards for a short range being obtained. For some years a torpedo 14 ft. long and 14 in. in diameter was considered large enough, though it had a very limited effective range. For a longer range a larger weapon must be employed capable of carrying a greater supply of air. To obtain this, torpedoes of 18 in. diameter, involving increased length and weight, have for some time been constructed, and have taken the place of the smaller torpedo in the equipment of warships. This advance in dimensions has not only given a faster and steadier torpedo, but enabled such a heavy charge of gun-cotton to be carried that its explosion against any portion of a ship would inevitably either sink or disable her. The dimensions, shape, &c., of the 14- and 18-in. torpedoes are shown in fig. 1. A limited range was still imposed by the uncertainty of its course under water. The speed of the ship from which it was discharged, the angle with her keel at which it entered the water, and the varying velocity of impulse, tended to error of flight, such error being magnified the farther the path of the torpedo was prolonged. Hence 800 yds. was formerly considered the limit of distance within which the torpedo should be discharged at sea against an object from a ship in motion.

In these circumstances, though improvements in the manufacture of steel and engines allowed of torpedoes of far longer range being made (the fastest torpedo up to 1898 having a speed of 29 knots for 800 yds.), it was of no advantage to make them, as they could not be depended upon to run in a straight line from a stationary point for more than 800 yds., while from a ship in motion good practice could only be ensured at a reduced range. It was obvious, therefore, that to increase the effective range of the torpedo, these errors of direction must be overcome by some automatic steering arrangement. Several inventors turned their attention to the subject, nearly all of whom proposed to utilize the principle of the gyroscope for the purpose. The first which gave any satisfactory results was an apparatus devised by Ludwig Obry—an engineer in Austria—and tried by the Italian government about 1896. These trials demonstrated the feasibility of accurately and automatically steering a torpedo in a direct line by this means. Messrs Whitehead & Co., of Fiume, then acquired the invention, and after exhaustive experiments produced the apparatus which is now fitted to every torpedo made. It is based on the principle that a body revolving on a free axis tends to preserve its plane of rotation. A gyroscope with plane of rotation parallel to the vertical axis of the torpedo will have an angular motion if the torpedo is diverted from its original course. This angular motion is employed to actuate the steering mechanism by operating an air motor connected with the rudders, and keeping the torpedo in the line of discharge. The apparatus consists of a flywheel caused to rotate by a spring, the barrel on which the latter is wound having a segmental wheel which gears into a toothed pinion spindle of the flywheel. Owing to the diameter of the segment being much greater than the pinion, a rapid rotatory motion is imparted. The spring is wound up by a key from outside the torpedo, and kept in tension until the projectile is discharged, when the spring is released by the air lever being thrown back, which admits air to the engine; the gyroscope is then freed and set in motion with its plane in the plane of the vertical axis of the torpedo as it was in the launching tube.

Assuming now that the course of the torpedo is diverted by any cause, its axis will move or perform a certain angular motion with regard to the plane of the flywheel, which will have the same result as if we consider the conditions reversed, *i.e.* as if the plane of rotation of the flywheel were altered and that of the axis of the torpedo remained the same. The axis of the flywheel performs a relative angular motion which it imparts to a crank actuating a servo-motor worked by compressed air, and connected with the rudders of the torpedo, moving them in the opposite direction to that in which the torpedo was diverted from its original course. Thus all inaccuracies of flight due to errors of adjustment, miscalculation of deflexion, or even damage to some part, are eliminated. As long as the gyroscope is in good order the torpedo is bound to run in the line it was pointing when the flywheel was started. It is placed in the after-body of the torpedo, as indicated in fig. 2.

limited by the strength of the engines and other parts. Improvements in steel manufacture have permitted the use of much higher pressures of air and the construction of air-chambers able to withstand the pressure of 2000 lb to the sq. in. with the same weight of air-chamber. This has enabled increased range without reduction in speed to be attained, or conversely, increased speed at shorter ranges. By improvement in the engines which are now of the Brotherhood 4-cylinder central crank type further gains have been effected.

Having reached the limit of pressure and endurance of air-chambers with present materials without undue increase of weight, the designer had to seek additional energy in another direction. Now the energy obtainable from a given weight of compressed air is dependent upon the volume of air available at the working pressure of the engines. At a constant pressure this volume of air is proportionate to its absolute temperature. If then the air be stored cold and highly heated before delivery to the engine the available energy from a given weight will be greatly increased. By this means we obtain the equivalent of a larger and heavier air-chamber without the increased weight such would involve.

As originally used a quantity of hydrocarbon fuel was placed in the air-vessel. Upon discharging the torpedo this fuel was automatically ignited and the contents of the air-chamber were heated. Unless, however, the combustion could be regulated there were serious risks of abnormal pressures, of overheating and weakening the air-vessel. Devices have been applied to overcome this liability, and other methods devised to obtain the same result.

By the use of heating and thereby increasing the volume of air in proportion to the rise of temperature the extra volume will allow of an increased speed for a given range or a greater range without increase of speed. The limit to the development of this system seems to be the temperature the materials will stand, but even at this early stage it has added several knots to the speed of this wonderful weapon.

Torpedo Carriages and Discharge.—As no gun which is inefficiently mounted can give good results, so the best torpedo is valueless without a good carriage or system of discharge. In the early days of the Whitehead, discredit came upon it because the importance of this was not sufficiently realized; and an erratic course under water was in nine cases out of ten due to a crude method of discharge. A delicate piece of mechanism was dropped into the water from a height of several feet, and naturally suffered internal derangement. Gun-ports were then used for the purpose, but now a special orifice is made, to which the torpedo carriage is fitted with a ball-and-socket joint—forming a water-tight aperture—so that this carriage or tube may be only 2 or 3 ft. above the water-line. The ball-and-socket joint enables it also to have a considerable angle of training. Originally the torpedo was pushed out by a rod acted upon by compressed air, in which case the carriage was a

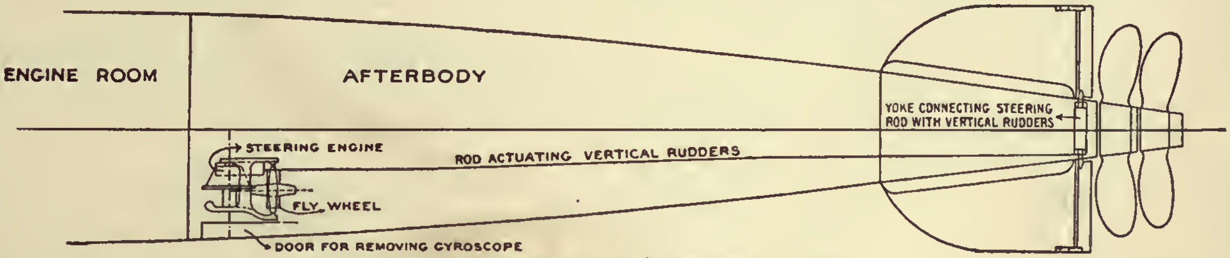

FIG. 2.—Arrangement of Gyroscope in Torpedo.

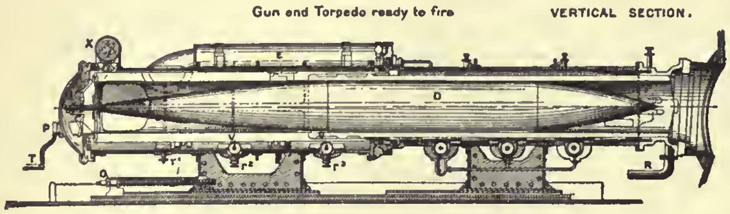
The efficiency of the Whitehead torpedo has thus been enormously increased, and more accurate practice can now be made at 2000 yds. than was formerly possible at 800 yds. This adds considerably to the chances of torpedo-boats attacking ships, even in day-time, at sea or at anchor, and will render further protection necessary against this weapon. Against a ship in motion there is still, however, the calculation as to her speed and the distance she will travel before the torpedo reaches her. Should this be miscalculated, an increased range for torpedoes will magnify the error. For instance, a 30-knot torpedo will travel 1000 yds. in a minute. If aimed at a ship on the beam assumed to be steaming 15 knots an hour, to reach her when 1000 yds. distant the torpedo must be discharged at a point 500 yds. ahead of her. But if the ship is actually steaming 12 knots, she will have travelled only 400 yds. in the minute, and the torpedo will be 100 yds. in advance of her. If discharged at a range of 500 yds., such a miscalculation causes an error of only 50 yds. or 150 ft. But if the object is 300 ft. long, and her centre was taken as the target, her bow would be just at the spot the torpedo would reach in thirty seconds. It would seem, therefore, that increased velocity of torpedo is necessary before the full advantages of the gyroscope can be realized. Now the range of the torpedo is entirely dependent upon the store of energy which can be carried; upon, therefore, the capacity of the air reservoir, the maximum pressure it can stand, and on the efficiency of the propelling engines. The speed over a given range is also dependent upon these factors; the maximum speed being

simple frame. The rod, pressing against the tail with some force, was apt to damage or disarrange the rudders, so the air-gun took the place of rod impulse. Here the torpedo fits closely in a tube or cylinder with an opening at the rear made air-tight when closed. At the desired moment compressed air is admitted to the rear part of the cylinder and blows the torpedo out. Gunpowder then superseded air for this operation; and now this has given place to a small charge of cordite, which does not leave any deposit on the inside of the cylinder. There is a double risk in the use of locomotive torpedoes from above water. (1) The charge may be exploded by hostile fire. Though mainly consisting of damp gun-cotton, which is not readily ignited, the dry primer and detonator may be struck, which would lead to a disastrous explosion. (2) The air-chamber is also a source of danger. As it contains air compressed to a high degree of tension, experiments have shown that if struck by a small shell it may burst with great violence; and as it offers a considerable mark, this is not an improbable event in an action. An instance of the danger of above-water torpedo tubes occurred in the Spanish-American War at the battle of Santiago. A shell entered the "Almirante Oquendo" and struck a 14-in. torpedo in the tube. The charge detonated, causing a fearful explosion and practically wrecking that part of the vessel. The development of moderate-sized quick-firing guns has increased this risk. Hence we find the use of above-water torpedo tubes now mainly confined to torpedo and other craft too small for submerged discharge.

Submerged Discharge.—The risk attached to having loaded torpedoes above the water-line—independently of the fact that to get the best result they should start in the element to which they belong—has given great impetus to the system of submerged discharge. From the earliest days of the weapon this has been employed to some extent. But it was principally in the direction of right-ahead fire, by having an orifice in the stem of the ship under water, to which a torpedo tube was connected. The tactical idea was thus to supplement attack with the ram, so that if the vessel endeavouring to ram saw that the object would evade this attack, she could project a torpedo ahead, which, travelling faster than the vessel, might as effectually accomplish the required service. The stem orifice had a water-tight cover, which was removed on the torpedo being placed in the tube and the inner door closed; then, sufficient impulse being imparted to eject the torpedo, and its machinery being set in motion at the same time, it darted forward towards the enemy. There is, however, some risk of the ship using a torpedo in this manner striking it before the missile has gathered the necessary impetus from its propellers to take it clear of the vessel. The system, moreover, has the disadvantage of weakening the ram, the construction of which should be of immense strength. There is the further liability of ramming with a torpedo in the bow tube, which would be as disastrous to friend as foe. This method of submerged discharge has therefore given place to ejecting the torpedo from the broadside. Considerable difficulty attached to getting the torpedo clear of the ship from this position without injury, especially when the vessel was proceeding at speed. The natural tendency of the passing water acting on the head of the torpedo as it emerged was to give a violent wrench and crush the rear end before that portion could clear the aperture. To prevent this the torpedo must be held rigid in the line of projection until the tail is clear of the ship. This is thus effected. Besides the tube with the aperture in side of the ship under water, fitted with sluice-valve, all broadside submerged discharge apparatus possess the following features: A shield is pushed out from the ship's side. In this shield there are grooves of some form. Guides on the torpedoes fit and run in these grooves. When discharged the torpedo is thus supported against the streams of passing water, and guided so that its axis continues in the line of projection until the tail is clear of the side, the shield being of such length that this occurs at the same time that the guides on the torpedo leave the grooves in the shield. An apparatus on this principle has been fitted to a number of ships of the British navy, and gives good results at high rates of speed. It has the defect that the shield must be run out previous to the torpedo being discharged, and brought back afterwards, thus involving three separate operations, each performed by compressed air.

In the broadside submerged discharge, designed, constructed and supplied to many foreign navies by Messrs Armstrong of the Elswick works, the three operations are combined in one. There is an outer tube as before, but it contains an inner tube carrying the torpedo. Fized to this tube, and prolonging it, is the shield fitted with grooves. Both tubes have a door at the rear—made air-tight when closed—by which the torpedo is entered. A charge of cordite is used for ejection instead of compressed air, the gas from which entering the outer cylinder first forces the inner tube out, and then by means of a valve in the door of the inner tube passes in and blows out water and torpedo together, the shield supporting the latter until the tail is clear of the ship. By this time the cordite gas has expanded and cooled so as to relieve the pressure in rear; this causes the pressure of the water outside to push the shield and tube into the ship again, so that practically the whole operation is one motion.



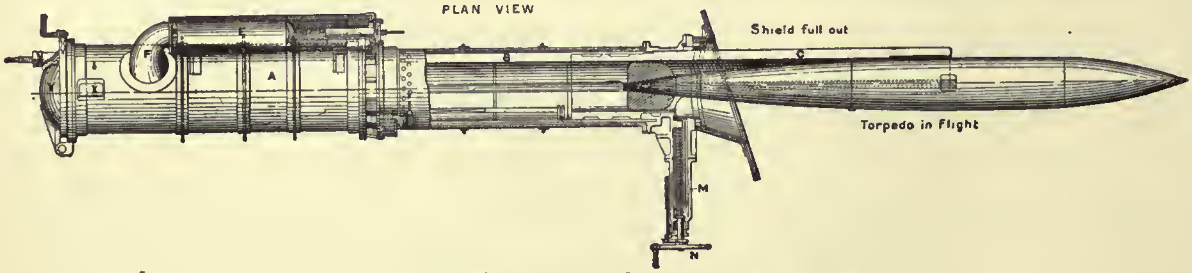


FIG. 3.—Broadside Submerged 18-in. Torpedo Tube.

Fig. 3 will further explain this apparatus. *A* is the outer tube; *B* the inner tube; *C* the shield; *D* torpedo; *E* explosion chamber for cordite charge placed at *K*; *F* pipe for gas to pass into outer tube; *G* and *Y* doors of inner and outer tube; *J* the valve which opens automatically when inner tube arrives at position shown in fig. 2; *T* and *P* appliance for running the tube in and out by hand when desired; *O* arrangement for bringing whole apparatus back for repair, &c.; *M* and *N* sluice-valve and handle; R, r^1, r^2, r^3, for draining tubes before torpedo is put in; *X* indicator showing position of inner tube.

Torpedoes have been discharged from this apparatus with successful result from a ship steaming at 17½ knots.

The advantage of cordite over compressed air for impulse is that it requires no attention: when a charge is placed in the explosion chamber, and a torpedo is in the tube, all is in readiness for firing when desired, without further attention in the torpedo-room. The cordite is fired by electricity from the conning-tower; the officer, therefore, having ascertained that all is ready below, has only to press a button when the object is in the required position. Automatic indications are given in the conning-tower when the sluice-valve is opened and when all is in readiness for firing.

This method of discharging torpedoes from the broadside under water eliminates the principal danger of the system, which required the shield to be put into position beforehand. It was then liable to be struck and distorted by passing wreckage without the fact being apparent to those in the ship. On the discharge of a torpedo its course might thus be arrested, or possibly the charge be prematurely exploded in dangerous proximity to its own ship. There was a risk of getting the shield out too soon, and thereby exposing it unduly to injury, or leaving the operation until too late. The tendency of naval equipment being towards complication, any readjustment which makes for simplicity cannot be otherwise than beneficial, and this feature is especially desirable in all matters connected with the use of torpedoes.

The compartment containing the broadside submerged apparatus usually extends across the ship, so as to contain a tube for each side.

Use in War.—This has been mainly confined to attacks upon squadrons and single ships by torpedo craft of various types. At the battle of Yalu, between the Chinese and Japanese fleets, torpedoes were discharged by the former, but none took effect. The Japanese trusted solely to gun-fire. After the defeat of the Chinese at sea, their remaining ships took refuge in the harbour of Wei-hai-Wei. Here they were blockaded by the Japanese fleet, which, having a number of torpedo-boats, made several determined attacks upon the ships inside. After one or two attempts, foiled by the obstructions placed by the Chinese to bar the passage, the Japanese boats succeeded in torpedoing several ships, and thus expedited the reduction of the place. In the war between Spain and the United States the inferiority of Admiral Cervera's squadron to that under Admiral Sampson might at the battle of Santiago have been to some extent counterbalanced by a skilful and vigorous use of torpedoes. If, instead of striving only to escape, a bold dash had been made for the American ships, the Spanish cruisers rapidly approaching end on to the foe, enveloped in the smoke of their own guns, should—some at least—have got within torpedo range without fatal injury. Closing each other at a speed of 10 knots only they would cover an interval of 6000 yds. in 9 minutes—a short time in which to disable a ship by gun-fire under such conditions. But Cervera elected to offer a passive resistance only, and while suffering destruction wrought no material injury upon his opponents. On the other hand, there have been several instances of large warships being sunk by locomotive torpedoes discharged from small craft. During the Chilean revolutionary war of 1891, a battleship, the "Blanco Encalada," of 3500 tons, was attacked in Caldera Bay by two torpedo vessels —the "Lynch" and "Condell"—of 750 tons. They entered the bay at dawn, the "Condell" leading. This vessel fired three torpedoes which missed the ironclad; then the "Lynch," after one ineffective shot, discharged a second torpedo, which struck the "Blanco" on the side nearly amidships. The latter had opened fire with little result, and sank soon afterwards. A similar incident occurred in 1894, when the Brazilian ironclad "Aquidaban" was sunk in Catherina Bay by the "Sampaio"—a torpedo vessel of 500 tons. She entered the bay at night, and first discharged her bow torpedo at the ironclad, which missed; she then fired a broadside torpedo, which struck and exploded against the bow of the "Aquidaban." It caused a great shock on board, throwing an officer on the bridge into the water. The vessel sank soon afterwards, and the "Sampaio" escaped uninjured.

In the war (1904–5) between Russia and Japan the Whitehead torpedo did not exercise an important influence upon the naval operations. It scored a success at the beginning of the struggle when a Japanese torpedo-flotilla made an attack upon the Russian fleet lying at anchor outside Port Arthur. For some unaccountable reason, though war was imminent, little or no precautions seemed to have been taken for effectually guarding the vessels. They had no nets in position nor boats patrolling outside them. Thus taken by surprise when the Japanese torpedo-boats suddenly appeared about midnight on the 8th of February 1904, several Russian ships were struck by torpedoes before they could offer any resistance. The most damaged were the "Retvisan" and "Tsarevitch" (battleships) and "Pallada" (cruiser), but all managed to get into Port Arthur and were eventually repaired. With three ships *hors de combat* the Russian fleet was considerably weakened at an early stage. The loss of the "Petropavlovsk" in April from a mine explosion was a further discouragement, especially as with this ship went down the gallant and energetic Admiral Makarov. In these circumstances the Russian fleet could not assume the offensive nor prevent the Japanese troops being sent by sea to invest Port Arthur. In June when the injured vessels were fit for service again the fleet put to sea but returned the same evening. The incident is noteworthy only because it led to an attack by the Japanese torpedo craft on the retiring squadron after sunset. As illustrating the uncertainty of hitting a moving object at sea with the Whitehead torpedo, already mentioned, no vessels were struck on this occasion and they reached the anchorage uninjured. In the battle of Tsushima the Japanese torpedo-boats attacked the Russian fleet after its disablement by gun-fire and gave the *coup de grâce* to some of the ships, which had little power of resistance owing to the destruction of their light armament. This war, therefore, did not increase to any extent our knowledge of the actual capability of this weapon.

Effect upon Naval Tactics: Blockade.—It has often been assumed that steam and the torpedo will in future render blockade impossible as it was carried out in the old wars; that, no longer dependent upon the wind to allow egress from the blockaded port, a vessel using steam can emerge when she chooses, while the fear of torpedo attack will deter a blockading squadron from keeping such watch as to foil the attempt. As regards the power conferred by steam, it will be no less advantageous to a blockading squadron, enabling it to maintain its position, whereas sailing ships were often driven by gales to leave their station and seek a port. This gave opportunities for the blockaded vessels to escape. As regards torpedo-boats, they would no doubt be a danger to a blockading squadron unprovided with a means of defence against these craft. Such defence consists in an adequate number of small vessels interposing an in-shore squadron between the port and the main body outside. Thus they perform the twofold service of watching the enemy's movements within and frustrating a torpedo attack. As an instance of blockade under modern conditions, we have that of Admiral Sampson upon Santiago—a guard more rigidly maintained than any in the old wars. So little was he deterred by the knowledge that Admiral Cervera had two torpedo vessels in his force, that he drew his squadron closer in at night when an attack might be expected, actually illuminating the entrance of the harbour with his electric searchlights, so that no craft could come out unperceived. No attempt was made to dislodge him from that position, and we may assume that blockade, if required in any scheme of naval strategy, will be carried out, whatever the weapons of warfare.

As regards the effect of torpedoes upon tactics at sea, and in general, as well as single ship, actions, they must operate against close range and employment of the ram. If it is recognized that a vessel within 1000 yds. is liable to a fatal blow, she will endeavour in ordinary circumstances to keep outside that distance and rely upon gun-fire. The exception would be where she is overmatched in that respect, and hence might endeavour to restore the balance by the use of torpedoes. In a fleet action the danger of missing a foe and hitting a friend would restrict the discharge of torpedoes; and this risk increases as formations disappear. But the torpedo must be conceded a tactical superiority over the ram for the following reasons: A vessel to use the latter must come within torpedo range, while her adversary may successfully apply torpedoes without placing herself in any danger of being rammed. The ram can only be used in one direction, and a small miscalculation may cause disaster. If a vessel has more than one position from which torpedoes can be discharged, she is not confined as regards attack to a single bearing or direction.

In action we may consider the speed of the torpedo as double that of the ship, and since against a moving object allowance must be made for the space traversed while ram or torpedo is travelling towards it, the faster weapon is less affected in its chance of successful impact by change of direction and speed of the object at the last moment. Lastly, with machinery disabled a ship is powerless to use the ram, but can avert a ram attack with her torpedoes. The movements of squadrons or single ships on entering an action are not likely to be influenced by any contemplated immediate use of torpedoes, for the gun must remain the primary weapon, at any rate at the first onset. Commanders would hardly risk being crushed by gun-fire before getting within torpedo range. Having faith in the efficiency of their ordnance and the gunnery skill of their crew, they would first manœuvre to bring these into play. Tactics for torpedo attack in such circumstances have not therefore been laid down, and it is only necessary to consider the positions which are advantageous for the use of this weapon, and, conversely, what should be avoided when a vessel, finding herself overmatched in gunnery, seeks to redress the balance with torpedoes.

Size of Target.—This, with a ship, varies in length as the torpedo approaches end on to the vessel, or at angle to the line of keel; the greatest being when the path of both forms a right angle. Hence the object is to place your ship where it presents the former condition to the enemy, while he affords the larger target. It must be remembered that, owing to the comparatively slow velocity of the torpedo, it must be aimed not directly at a ship in motion—like a shot from a gun—but at a point ahead which the ship will reach after the torpedo has traversed the intervening distance. Thus speed of object has to be estimated, and hence the importance of adding to the velocity of the torpedo and getting a broadside shot so as to reduce as much as possible errors of calculation. The great increase of the dimensions of warships, especially in length, which now has reached 500 ft., adds to the chances of a successful hit with torpedoes, and will doubtless tend to diminish a desire in future naval tactics to close inside torpedo range for the purpose of ramming.

Range.—Though the effective range of a torpedo discharged from a ship or torpedo vessel against a single object moving at high speed may be considered as approximately within 1000 yds. this limit of distance is considerably augmented where the target consists of several vessels at sea in close order, or is that afforded by a fleet at anchor. In the first case it may be worth while to discharge torpedoes from a distance of two or three thousand yards at the centre of the line for the chance of hitting one of the vessels composing it. As regards a mass of ships at anchor, unless protected by an impenetrable guard such as a breakwater or some invulnerable defence carried by the ships themselves, the increased range and accuracy of the torpedo imparted by recent developments would give it a chance of success if discharged against such a target at even greater distance.

Finally, by improvements in construction and methods of discharge the torpedo has recovered the place it was rapidly losing a few years ago. As armour receives increased resisting power to above-water projectiles, and gets on a level again with the gun, more attention will be given to under-water attack, against which no adequate protection has yet been devised. Thus we shall probably find the torpedo taking a very prominent place in any future war between the great maritime powers. (S. M E.-W.)

TORQUAY, a municipal borough, seaport and watering place, in the Torquay parliamentary division of Devonshire, England, on Tor Bay of the English Channel, 26 m. S. of Exeter, by the Great Western railway. Pop. (1901), 33,625. Owing to the beauty of its site and the equability of its climate, and to its being screened by lofty hills on the north, east and west, and open to the sea-breezes of the south, it has a high reputation as a winter residence. The temperature seldom rises as high as 70° F. in summer or falls below freezing-point in winter. To the north lies the populous suburb of St Mary Church. There are some remains of Tor or Torre Abbey, founded for Praemonstratensians by William, Lord Brewer, in 1196. They stand north of the modern mansion, but, with the exception of a beautiful pointed arch portal, are of small importance. On the south of the gateway is a 13th-century building, known as the Spanish barn. On Chapel Hill are the remains of a chapel of the 12th century, dedicated to St Michael, and supposed to have formerly belonged to the abbey. St Saviour's parish church of Tor-Mohun, or Tormoham, an ancient stone structure, was restored in 1874. The old church at St Mary Church, north of Torquay, was rebuilt in Early Decorated style; and in 1871 a tower was erected as a memorial to Dr Phillpotts, bishop of Exeter, who with his wife is buried in the churchyard. St John's Church, by G. E. Street, is a fine example of modern Gothic. Among the principal buildings and institutions are the town-hall, museum of the natural history society, theatre and opera-house (1880), market, schools of art and science, the Torbay infirmary and dispensary, the Western hospital for consumption, Crypt House institution for invalid ladies and the Mildmay home for incurable consumptives. The control of the harbour, piers, pleasure grounds, &c., was acquired from the lord of the manor by the local board in 1886. The harbour has a depth of over 20 ft. at low water. The principal imports are coal, timber and slates, and the principal export stone of the Transition limestone or Devonshire marble. In the town are a number of marble-polishing works. Terra-cotta ware of fine quality is also manufactured from a deposit of clay at Watcombe and at Hele. The town is governed by a mayor, 9 aldermen and 27 councillors. Area, 3588 acres.

There was a village at Torre even before the foundation of the abbey, and in the neighbourhood of Torre evidence has been found of Roman occupation. The manor was granted by William the Conqueror to Richard de Bruvere or de Brewere, and was subsequently known as Tor Brewer. After the defeat of the Spanish Armada, Don Pedro's galley was brought into Torbay; and William, prince of Orange, landed at Torbay on the 5th of November 1688. Until the middle of the 19th century it was an insignificant fishing village. It was incorporated in 1892.

TORQUE, or TORC (Lat. *torquis*, *torques*, a twisted collar, *torquere*, to twist), the term given by archaeologists to the twisted collars or armlets of gold or other metal worn particularly by the ancient Gauls and other allied Celtic races. The typical torque is a circlet with twisted rope-like strands, the ends not joined together; the torque was usually worn with the opening in the front as seen in a figure of a Gaul in a sculptured sarcophagus in the Capitoline Museum at Rome. In mechanics, the term "torque" is used of the turning-moment of a system-force, as in a series dynamo.

TORQUEMADA, JUAN DE (1388–1468), or rather JOHANNES DE TURRECREMATA, Spanish ecclesiastic, was born at Valladolid, in 1388, and was educated in that city. At an early age he joined the Dominican order, and soon distinguished himself for learning and devotion. In 1415 he accompanied the general of his order to the Council of Constance, whence he proceeded to Paris for study, and took his doctor's degree in 1423. After teaching for some time in Paris he became prior of the Dominican house first in Valladolid and then in Toledo. In 1431 Pope Eugenius IV. called him to Rome and made him "magister sancti palatii." At the Council of Basel he was one of the ablest supporters of the view of the Roman curia, and he was rewarded with a cardinal's hat in 1439. He died at Rome on the 26th of September 1468.

His principal works are *In Gratiani Decretum commentarii* (4 vols., Venice, 1578); *Expositio brevis et utilis super toto psalterio* (Mainz, 1474); *Quaestiones spirituales super evangelia totius anni* (Brixen, 1498); *Summa ecclesiastica* (Salamanca, 1550). The last-named work has the following topics: (1) De universa ecclesia; (2) De Ecclesia romana et pontificis primatu; (3) De universalibus conciliis; (4) De schismaticis et haereticis. His *De conceptione deiparae Mariae, libri viii.* (Rome, 1547), was edited with preface and notes by E. B. Pusey (London, 1869 seq.).

TORQUEMADA, THOMAS (1420–1498), inquisitor-general of Spain, son of Don Pedro Ferdinando, lord of Torquemada, a small town in Old Castile, was born in 1420 at Valladolid during the reign of John II. Being nephew to the well-known cardinal of the same name, he early displayed an attraction for the Dominican order; and, as soon as allowed, he joined the Friars Preachers in their convent at Valladolid. His biographers state that he showed himself from the beginning very earnest in austere life and humility; and he became a recognized example of the virtues of a Dominican. Valladolid was then the capital, and in due course eminent dignities were offered to him, but he gave signs of a determination to lead the simple life of a Friar Preacher, In the convent, his modesty was so great that he refused to accept the doctor's degree in theology, which is the highest prized honour in the order. His superiors, however, obliged him to take the priorship of the convent of Santa Cruz in Segovia, where he ruled for twenty-two years. The royal family, especially the queen and the infanta Isabella, often stayed at Segovia, and Torquemada became confessor to the infanta, who was then very young. He trained her to look on her future sovereignty as an engagement to make religion respected. Esprit Flechier, bishop of Nîmes, in this *Histoire du cardinal Jimenes* (Paris, 1693), says that Torquemada made her promise that when she became queen she would make it her principal business to chastise and destroy heretics. He then began to teach her the political advantages of religion and to prepare the way for that tremendous engine in the hands of the state, the Inquisition.

Isabella succeeded to the throne (1474) on the death of Henry IV. Torquemada had always been strong in his advice that she should marry Ferdinand of Aragon and thus consolidate the kingdoms of Spain. Hitherto he had rarely appeared at court; but now the queen entrusted him not only with the care of her conscience, but also with the benefices in the royal patronage. He also helped her in quieting Ferdinand, who was chafing under the privileges of the Castilian grandees, and succeeded so well that the king also took him as confessor. Refusing the rich see of Seville and many other preferments he accepted that of councillor of state. For a long time he had pondered over the confusion in which Spain was, which he attributed to the intimate relations allowed between Christians and infidels for the sake of commerce. He saw Jews, Saracens, heretics and apostates roaming through Spain unmolested; and in this lax toleration of religious differences he thought he saw the main obstacle to the political union of the Spains, which was the necessity of the hour. He represented to Ferdinand and Isabella that it was essential to their safety to reorganize the Inquisition, which had since the 13th century (1236) been established in Spain. The bishops, who were *ex officio* inquisitors in their own dioceses, had not succeeded in putting a stop to the evils, nor had the friars, by whom they had been practically superseded. By the middle of the 15th century there was hardly an active inquisitor left in the kingdom. In 1473 Torquemada and Gonzalez de Mendoza, archbishop of Toledo, approached the sovereigns. Isabella had been for many years prepared, and she and Ferdinand, now that the proposal for this new tribunal came before them, saw in it a means of overcoming the independence of the nobility and clergy by which the royal power had been obstructed. With the royal sanction a petition was addressed to Sixtus IV. for the establishment of this new form of Inquisition; and as the result of a long intrigue, in 1479 a papal bull authorized the appointment by the Spanish sovereigns of two inquisitors at Seville, under whom the Dominican inquisitions already established elsewhere might serve. In the persecuting activity that ensued the Dominicans, "the Dogs of the Lord" (*Domini canes*), took the lead. Commissaries of the Holy Office were sent into different provinces, and ministers of the faith were established in the various cities to take cognisance of the crimes of heresy, apostasy, sorcery, sodomy and polygamy, these three last being considered to be implicit heresy. The royal Inquisition thus started was subversive of the regular tribunals of the bishops, who much resented the innovation, which, however, had the power of the state at its back.

In 1481, three years after the Sixtine commission, a tribunal was inaugurated at Seville, where freedom of speech and licence of manner were rife. The inquisitors at once began to detect errors. In order not to confound the innocent with the guilty, Torquemada published a declaration offering grace and pardon to all who presented themselves before the tribunal and avowed their fault. Some fled the country, but many (Mariana says 17,000) offered themselves for reconciliation. The first seat of the Holy Office was in the convent of San Pablo, where the friars, however, resented the orders, on the pretext that they were not delegates of the inquisitor-general. Soon the gloomy fortress of Triana, on the opposite bank of the Guadalquivir, was prepared as the palace of the Holy Office; and the terror-stricken Sevillianos read with dismay over the portals the motto of the Inquisition: "Exsurge, Domine, Judica causam tuam, Capite nobis vulpes." Other tribunals, like that of Seville and under *La Suprema*, were speedily established in Cordova, Jaen and Toledo. The sovereigns saw that wealth was beginning to flow in to the new tribunals by means of fines and confiscations; and they obliged Torquemada to take as assessors five persons who would represent them in all matters affecting the royal prerogatives. These assessors were allowed a definite vote in temporal matters but not in spiritual, and the final decision was reserved to Torquemada himself, who in 1483 was appointed the sole inquisitor-general over all the Spanish possessions. In the next year he ceded to Diego Deza, a Dominican, his office of confessor to the sovereigns, and gave himself up to the congenial work of reducing heretics. A general assembly of his inquisitors was convoked at Seville for the 29th of November 1484; and there he promulgated a code of twenty-eight articles for the guidance of the ministers of the faith. Among these rules are the following, which will give some idea of the procedure. Heretics were allowed thirty days to declare themselves. Those who availed themselves of this grace were only fined, and their goods escaped confiscation. Absolution *in foro externo* was forbidden to be given secretly to those who made voluntary confession; they had to submit to the ignominy of the public *auto-de-fé*. The result of this harsh law was that numerous applications were made to Rome for secret absolution; and thus much money escaped the Inquisition in Spain. Those who were reconciled were deprived of all honourable employment, and were forbidden to use gold, silver, jewelry, silk or fine wool. Against this law, too, many petitions went to Rome for rehabilitation, until in 1498 the Spanish pope Alexander VI. granted leave to Torquemada to rehabilitate the condemned, and withdrew practically all concessions hitherto made and paid for at Rome. Fines were imposed by way of penance on those confessing willingly. If a heretic in the Inquisition asked for absolution, he could receive it, but subject to a life imprisonment; but if his repentance were but feigned he could be at once condemned and handed over to the civil power for execution. Should the accused, after the testimony against him had been made public, continue to deny the charge, he was to be condemned as impenitent. When serious proof existed against one who denied his crime, he could be submitted to the question by torture; and if under torture he avowed his fault and confirmed his guilt by subsequent confession he was punished as one convicted; but should he retract he was again to be submitted to the tortures or condemned to extraordinary punishment. This second questioning was afterwards forbidden; but the prohibition was got over by merely suspending and then renewing the sessions for questioning. It was forbidden to communicate to the accused the entire copy of the declaration of the witnesses. The dead even were not free from the Holy Office; but processes could be instituted against them and their remains subjected to punishment. But along with these cruel and unjust measures there must be put down to Torquemada's credit some advanced ideas as to prison life. The cells of the Inquisition were, as a rule, large, airy, clean and with good windows admitting the sun. They were, in those respects, far superior to the civil prisons of that day. The use of irons was in Torquemada's time not allowed in the Holy Office; the use of torture was in accordance with the practice of the other royal tribunals; and when these gave it up the Holy Office did so also.

Such were some of the methods that Torquemada introduced into the Spanish Inquisition, which was to have so baneful an effect upon the whole country. During the eighteen years that he was inquisitor-general it is said that he burnt 10,220 persons, condemned 6860 others to be burnt in effigy, and reconciled 97,321, thus making an average of some 6000 convictions a year. These figures are given by Llorente, who was secretary of the Holy Office from 1790 to 1792 and had access to the archives; but modern research reduces the list of those burnt by Torquemada to 2000, in itself an awful holocaust to the principle of intolerance. The constant stream of petitions to Rome opened the eyes of the pope to the effects of Torquemada's severity. On three separate occasions he had to send Fray Alfonso Badaja to defend his acts before the Holy See. The sovereigns, too, saw the stream of money, which they had hoped for, diverted to the coffers of the Holy Office, and in 1493 they made complaint to the pope; but Torquemada was powerful enough to secure most of the money for the expenses of the Inquisition. But in 1496, when the sovereigns again complained that the inquisitors were, without royal knowledge or consent, disposing of the property of the condemned and thus depriving the public revenues of considerable sums, Alexander VI. appointed Jimenes to examine into the case and make the Holy Office disgorge the plunder.

For many years Torquemada had been persuading the sovereigns to make an attempt once for all to rid the country of the hated Moors. Mariana holds that the founding of the Inquisition, by giving a new impetus to the idea of a united kingdom, made the country more capable of carrying to a satisfactory ending the traditional wars against the Moors. The taking of Zahaia in 1481 by the enemy gave occasion to reprisals. Troops were summoned to Seville and the war began by the siege of Alhama, a town eight leagues from Granada, the Moorish capital. Torquemada went with the sovereigns to Cordova, to Madrid or wherever the states-general were held, to urge on the war; and he obtained from the Holy See the same spiritual favours that had been enjoyed by the Crusaders. But he did not forget his favourite work of ferreting out heretics; and his ministers of the faith made great progress over all the kingdom, especially at Toledo, where merciless severity was shown to the Jews who had lapsed from Christianity. The Inquisition, although as a body the clergy did not mislike it, sometimes met with furious opposition from the nobles and common people. At Valentia and Lerida there were serious conflicts. At Saragossa Peter Arbuê, a canon and an ardent inquisitor, was slain in 1485 whilst praying in a church; and the threats against the hated Torquemada made him go in fear of his life, and he never went abroad without an escort of forty familiars of the Holy Office on horseback and two hundred more on foot. In 1487 he went with Ferdinand to Malaga and thence to Valladolid, where in the October of 1488 he held another general congregation of the Inquisition and promulgated new laws based on the experience already gained. He then hurried back to Andalusia where he joined the sovereigns, who were now besieging Granada, which he entered with the conquering army in January 1492 and built there a convent of his order.

The Moors being vanquished, now came the turn of the Jews. In 1490 had happened the case of El Santo niño de la Guardia—a child supposed to have been killed by the Jews. His existence had never been proved; and in the district of Guardia no child was reported as missing. The whole story was most probably the creation of imaginations stimulated by torture and despair, unless it was a deliberate fiction set forth for the purpose of provoking hostility against the Jews. For a long time Torquemada had tried to get the royal consent to a general expulsion; but the sovereigns hesitated, and, as the victims were the backbone of the commerce of the country, proposed a ransom of 300,000 ducats instead. The indignant friar would hear of no compromise: "Judas," he cried, "sold Christ for 30 pence; and your highnesses wish to sell Him again for 300,000 ducats." Unable to bear up against the Dominican's fiery denunciations, the sovereigns, three months after the fall of Granada, issued a decree ordering every Jew either to embrace Christianity or to leave the country, four months being given to make up their minds; and those who refused to become Christians to order had leave to sell their property and carry off their effects. But this was not enough for the inquisitor-general, who in the following month (April) issued orders to forbid Christians, under severe penalties, having any communication with the Jews or, after the period of grace, to supply them even with the necessaries of life. The former prohibition made it impossible for the unfortunate people to sell their goods which hence fell to the Inquisition. The numbers of Jewish families driven out of the country by Torquemada is variously stated from Mariana's 1,700,000 to the more probable 800,000 of later historians. The loss to Spain was enormous, and from this act of the Dominican the commercial decay of Spain dates.

Age was now creeping on Torquemada, who, however, never would allow his misdirected zeal to rest. At another general assembly, his fourth, he gave new and more stringent rules, which are found in the *Compilación de las instrucciones del officio de la Santa Inquisición*. He took up his residence in Avila, where he had built a convent; and here he resumed the common life of a friar, leaving his cell in October 1497 to visit, at Salamanca, the dying infante, Don Juan, and to comfort the sovereigns in their parental distress. They often used to visit him at Avila, where in 1498, still in office as inquisitor-general, he held his last general assembly to complete his life's work. Soon afterwards he died, on the 16th of September 1498, "full of years and merit" says his biographer. He was buried in the chapel of the convent of St Thomas in Avila.

The name of Torquemada stands for all that is intolerant and narrow, despotic and cruel. He was no real statesman or minister of the Gospel, but a blind fanatic, who failed to see that faith, which is the gift of God, cannot be imposed on any conscience by force. (E. Tn.)

TORRE ANNUNZIATA, a seaport of Campania, Italy, in the province of Naples, on the east of the Bay of Naples, and at the south foot of Mt Vesuvius, 14 m. S.E. of Naples by rail. Pop. (1901), 25,070 (town); 28,084 (commune). It is on the main line to Battipaglia, at the point of junction of a branch line from Cancello round the east of Vesuvius, and of the branch to Castellammare di Stabia and Gragnano. It has a royal arms factory established by Charles IV., and other ironworks, considerable manufacture of macaroni, paper, breeding of silkworms, and some fishing and shipping. The harbour is protected by moles. Remains attributed to the Roman post-station of Oplontis were discovered in making the railway between Torre del Greco and Torre Annunziata, a little west of the latter, in 1842.

TORRE DEL GRECO, a seaport of Campania, Italy, in the province of Naples, $7\frac{1}{2}$ m. S.E. of that city by rail. Pop. (1901), 35,328. It lies at the south-west foot of Vesuvius, on the shore of the Bay of Naples. It is built chiefly of lava, and stands on the lava stream of 1631, which destroyed two-thirds of the older town. Great damage was done by the eruptions of 1737 and 1794; the earthquake of 1857 and the eruption of the 8th of December 1861 were even more destructive. After each disaster the people returned, the advantage of the rich volcanic land overcoming apprehensions of danger. In the outskirts are many beautiful villas and gardens. The town has shipbuilding yards and lava quarries. The inhabitants take part in the coral and sponge fishing off the African and Sicilian coasts, and coral is worked in the town. There is also fishing for tunny, sardines and oysters; hemp is woven, and the neighbourhood is famed for its fruit and wine. In June the great popular festival "Dei Quattro Altari" is annually celebrated here in commemoration of the abolition of the feudal dominion in 1700. Remains of ancient villas and baths have been found here.

TORRENS, ROBERT (1780–1864), English soldier and economist, was born in Ireland in 1780. He entered the Marines in 1797, became a captain in 1806, and major in 1811 for bravery in Anhalt during the Walcheren expedition. He fought in the Peninsula, becoming lieutenant-colonel in 1835 and retiring as colonel in 1837. After abortive attempts to enter parliament in 1818 and 1826, he was returned in 1831 as member for Ashburton. He was a prolific writer, principally on financial and commercial policy. Almost the whole of the programme which was carried out in legislation by Sir Robert Peel had been laid down in his economic writings. He was an early and earnest advocate of the repeal of the corn laws, but was not in favour of a general system of absolute free trade, maintaining that it is expedient to impose retaliatory duties to countervail similar duties imposed by foreign countries, and a lowering of import duties on the productions of countries retaining their hostile tariffs would occasion a decline in prices, profits and wages.

His principal writings of a general character were: *The Economist* [*i.e.* Physiocrat] *refuted* (1808); *Essay on the Production of Wealth* (1821); *Essay on the External Corn-trade* (eulogized by Ricardo) (1827); *The Budget, a Series of Letters on Financial, Commercial and Colonial Policy* (1841–1843); *The Principles and Practical Operations of Sir Robert Peel's Act of 1844 Explained and Defended* (1847).

TORRENS, SIR ROBERT RICHARD (1814–1884), British colonial statesman, was born at Cork, Ireland, in 1814, and educated at Trinity College, Dublin. He went to South Australia in 1840, and was appointed collector of customs. He was an official member of the first legislative council and in 1852 was treasurer and registrar-general. When responsible government was established he was elected as a representative for Adelaide and became a member of the first ministry. In 1857 he introduced his famous Real Property Act, the principle of which consists of conveyance by registration and certificate instead of deeds. The system was rapidly adopted in the other colonies and elsewhere, and was expounded by the author during a visit to the United Kingdom in 1862–1864. After leaving South Australia, Sir R. R. Torrens represented Cambridge in the House of Commons from 1868 to 1874; in 1872 he was knighted. He was the author of works on the effect of the gold discoveries on the currency, and other subjects. He died on the 31st of August 1884.

TORRENS, WILLIAM TORRENS M'CULLAGH (1813–1894), English politician and social reformer, son of James M'Cullagh (whose wife's maiden name, Torrens, he assumed in 1863), was born near Dublin on the 13th of October 1813. He was called to the bar, and in 1835 became assistant commissioner on the special commission on Irish poor-relief, which resulted in the extension of the workhouse system in Ireland in 1838. In the 'forties he joined the Anti-Corn Law League, and in 1846 published his *Industrial History of Free Nations.* In 1847 he was elected to parliament for Dundalk, and sat till 1852. In 1857 he was elected as a Liberal for Yarmouth and from 1865 to 1885 he represented Finsbury. Torrens was a well known man in political life, and devoted himself mainly to social questions in parliament. It was an amendment of his to the Education Bill of 1870 which established the London School Board, and his Artisans' Dwellings Bill in 1868 facilitated the clearing away of slums by local authorities. He published several books, and his *Twenty Years in Parliament* (1893) and *History of Cabinets* (1894) contain useful material. He died in London on the 26th of April 1894.

TORRES NAHARRO, BARTOLOMÉ DE (1480–1530), Spanish dramatist, was born towards the end of the 15th century at Torres, near Badajoz. After some years of soldiering and of captivity in Algiers, Torres Naharro took orders, settled in Rome about 1511, and there devoted himself chiefly to writing plays. Though he alludes to the future pope, Clement VII. as his protector, he left Rome to enter the household of Fabrizio Colonna at Naples where his works were printed under the title of *Propaladia* (1517). He is conjectured to have returned to his native place, and to have died there shortly after 1529. His *Diálogo del nacimiento* is written in unavowed, though obvious, imitation of Encina, but in his subsequent plays he shows a much larger conception of dramatic possibilities. He classifies his pieces as *comedias á noticia* and *comedias á fantasia*; the former, of which the *Soldatesca* and *Tinellaria* are examples, present in dramatic form incidents within his personal experience; the latter, which include such plays as *Serafina, Himenea, Calamita* and *Aquilana*, present imaginary episodes with adroitness and persuasiveness. Torres Naharro is much less dexterous in stagecraft than many inferior successors, his humour is rude and boisterous and his diction is unequal; but to a varied knowledge of human nature he adds knowledge of dramatic effect, and his rapid dialogue, his fearless realism and vivacious fancy prepared the way for the romantic drama in Spain.

TORRES NOVAS, a town of Portugal, in the district of Santarem, 19 m. N.N.E. of Santarem on the Lisbon-Entroncamento railway. Pop. (1900), 10,746. It manufactures cottons, linens, jute, paper, leather and spirits. It was probably founded by Greeks, and was held by the Romans, Goths and Moors, from whom it was conquered in 1148 by Alphonso I. of Portugal.

TORRES VEDRAS, a town of Portugal, in the district of Lisbon, 43 m. N. by W. of Lisbon, on the Lisbon-Figueira da Foz railway. Pop. (1900), 6900. Torres Vedras is built on the left bank of the river Sizandro; it has a Moorish citadel and hot sulphur baths. Roman inscriptions and other remains have been found here, but the Latin name of the town, *Turres Veteres*, is probably medieval. Here were the noted fortifications known as the "lines of Torres Vedras," constructed by Wellington in 1810 (see PENINSULAR WAR). Here also in 1846 the troops of General Saldanha defeated those of the count de Bomfin and seized the castle and town (see PORTUGAL: *History*).

TORRES Y VILLAROEL, DIEGO DE (1696–1759?), Spanish miscellaneous writer, was born in 1696 at Salamanca, where his father was bookseller to the university. In his teens Torres escaped to Portugal where he enlisted under a false name; he next moved to Madrid, living from hand to mouth as a hawker; in 1717 he was ordained subdeacon, resumed his studies at Salamanca, and in 1726 became professor of mathematics at the university. A friend of his having stabbed a priest, Torres was suspected of complicity, and once more fled to Portugal, where he remained till his innocence was proved. He then returned to his chair, which he resigned in 1751 to act as steward to two noblemen; he was certainly alive in 1758, but the date of his death is not known. Torres had so slight a smattering of mathematics that his appointment as professor was thought scandalous even in his own scandalous age; yet he quickly acquired a store of knowledge which he displayed with serene assurance. His almanacs, his verses, his farces, his devotional and pseudo-scientific writings show that he possessed the alert adaptiveness of the born adventurer; but all that remains of his fourteen volumes (1745–1752) is his autobiography, an amusing record of cynical effrontery and successful imposture.

TORREVIEJA, a seaport of south-eastern Spain, in the province of Alicante, 3 m. S.W. of Cape Cervera, and at the terminus of a railway to Albatera on the Alicante-Murcia line. Pop. (1900), 7706. The district is famous for its salt beds, which are owned and worked by the state, the Laguna Grande alone yielding more than 100,000 tons a year. The other industries are chiefly fishing, shipbuilding and the manufacture of ropes and sails. The roadstead affords safe anchorage. There is an active trade in fruit and agricultural products.

TORREY, JOHN (1796–1873), American botanist, was born at New York on the 15th of August 1796. When he was 15 or 16 years of age his father received a prison appointment at Greenwich, and there he made the acquaintance of Amos Eaton (1776–1842), a pioneer of natural history studies in America. He thus learned the elements of botany, as well as something of mineralogy and chemistry. In 1815 he began the study of medicine, qualifying in 1818. In the following year he issued his *Catalogue of Plants growing spontaneously within Thirty Miles of the City of New York*, and in 1824 he issued the first and only volume of his *Flora of the Northern and Middle States.* In the same year he obtained the chair of chemistry and geology at West Point military academy, and three years later the professorship of chemistry and botany in the College of Physicians and Surgeons, New York. In 1836 he was appointed botanist to the state of New York and produced his *Flora* of that state in 1843; while from 1838 to 1843 he carried on the publication of the earlier portions of *Flora of North America*, with the assistance of his pupil, Asa Gray. From 1853 he was chief assayer to the United States assay office, but he continued to take an interest in botanical teaching until his death at New York on the 10th of March 1873. He made over his valuable herbarium and botanical library to Columbia College in 1860, and he was the first president of the Torrey Botanical Club in 1873. His name is commemorated in the small coniferous genus *Torreya*, found in North America and in China and Japan. *T. taxifolia*, a native of Florida, is known as the Torrey tree or savin, and also as the stinking cedar.

TORREY, REUBEN ARCHER (1856–), American evangelist, was born in Hoboken, New Jersey, on the 28th of January 1856. He graduated at Yale University in 1875 and at the Yale Divinity School in 1878. He became a Congregational minister in 1878, studied theology at Leipzig and Erlanger in 1882–1883, joined D. L. Moody in his evangelistic work in Chicago in 1889, and became pastor of the Chicago Avenue Church in 1894 and afterwards superintendent of the Moody Bible Institute of Chicago. In 1902–1903 he preached in nearly every part of the English-speaking world, and with Charles McCallon Alexander (b. 1867) conducted revival services in Great Britain in 1903–1905; Torrey conducted a similar campaign in American and Canadian cities in 1906–1907.

TORRICELLI, EVANGELISTA (1608–1647), Italian physicist and mathematician, was born at Faenza on the 15th of October 1608. Left fatherless at an early age, he was educated under the care of his uncle, a Camaldolese monk, who in 1627 sent him to Rome to study science under the Benedictine Benedetto Castelli (1577–1644), professor of mathematics at the Collegio di Sapienza. The perusal of Galileo's *Dialoghi delle nuove scienze* (1638) inspired him with many developments of the mechanical principles there set forth, which he embodied in a treatise *De motu* (printed amongst his *Opera geometrica*, 1644). Its communication by Castelli to Galileo in 1641, with a proposal that Torricelli should reside with him, led to Torricelli repairing to Florence, where he met Galileo, and acted as his amanuensis during the three remaining months of his life. After Galileo's death Torricelli was nominated grand-ducal mathematician and professor of mathematics in the Florentine academy. The discovery of the principle of the barometer (*q.v.*) which has perpetuated his fame ("Torricellian tube" "Torricellian vacuum") was made in 1643.

The publication amongst Torricelli's *Opera geometrica* (Florence, 1644) of a tract on the properties of the cycloid involved him in a controversy with G. P. de Roberval, who accused him of plagiarizing his earlier solution of the problem of its quadrature. There seems, however, no room for doubt that Torricelli's was arrived at independently. The matter was still in debate when he was seized with pleurisy, and died at Florence on the 25th of October 1647. He was buried in San Lorenzo, and a commemorative statue of him erected at Faenza in 1864.

Among the new truths detected by him was the valuable mechanical principle that if any number of bodies be so connected that, by their motion, their centre of gravity can neither ascend nor descend, then those bodies are in equilibrium. He also discovered the remarkable fact that the parabolas described (in a vacuum) by indefinitely numerous projectiles discharged from the same point with equal velocities, but in all directions have a paraboloid of revolution for their envelope. His theorem that a fluid issues from a small orifice with the same velocity (friction and atmospheric resistance being neglected) which it would have acquired in falling through the depth from its surface is of fundamental importance in hydraulics. He greatly improved both the telescope and microscope. Several large object lenses, engraven with his name, are preserved at Florence. He used and developed B. Cavalieri's method of indivisibles.

A selection from Torricelli's manuscripts was published by Tommaso Bonaventura in 1715, with the title *Lezioni accademiche* (Florence). They include an address of acknowledgment on his admission to the Accademia della Crusca. His essay on the inundations of the Val di Chiana was printed in *Raccolta d'autori che trattano del moto dell' acque*, iv. 115 (Florence, 1768), and amongst *Opusculi idraulici*, iii. 347 (Bologna, 1822). For his life see Fabroni, *Vitae Italorum*, i. 345; Ghinassi, *Lettere fin qui inedite di Evangelista Torricelli* (Faenza, 1864); Tiraboschi, *Storia della lett. it.* viii. 302 (ed. 1824); Montucla, *Hist. des math.*, vol. ii.; Marie, *Hist. des sciences*, iv. 133.

TORRIDONIAN, in geology, a series of pre-Cambrian arenaceous sediments extensively developed in the north-west highlands of Scotland and particularly in the neighbourhood of upper Loch Torridon, a circumstance which suggested the name Torridon Sandstone, first applied to these rocks by J. Nicol. The rocks are mainly red and chocolate sandstones, arkoses, flagstones and shales with coarse conglomerates locally at the base. Some of the materials of these rocks were derived from the underlying Lewisian gneiss, upon the uneven surface of which they rest; but the bulk of the material was obtained from rocks that are nowhere now exposed. Upon this ancient denuded land surface the Torridonian strata rest horizontally or with gentle inclination. Their outcrop extends in a belt of variable breadth from Cape Wrath to the Point of Sleet in Skye, running in a N.N.E.–S.S.W. direction through Ross-shire and Sutherlandshire. They form the isolated mountain peaks of Canisp, Quinag and Suilven in the neighbourhood of Loch Assynt, of Slioch near Loch Maree and other hills. They attain their maximum development in the Applecross, Gairloch and Torridon districts, form the greater part of Scalpay, and occur also in Rum, Raasay, Soay and the Crowlin Islands. The Torridonian rocks have been subdivided into three groups: an upper Aultbea group, 3000–5000 ft.; a middle or Applecross group, 6000–8000 ft.; and a lower or Diabeg group, 500 ft. in Gairloch but reaching a thickness of 7200 ft. in Skye.

See "The Geological Structure of the North-West Highlands of Scotland," *Mem. Geol. Survey* (Glasgow, 1907). (J. A. H.)

TORRIGIANO, PIETRO (1472–1522), Florentine sculptor, was, according to Vasari, one of the group of talented youths who studied art under the patronage of Lorenzo the Magnificent in Florence. Benvenuto Cellini, reporting a conversation with Torrigiano, relates that he and Michelangelo, while both young, were copying the frescoes in the Carmine chapel, when some slighting remark made by Michelangelo so enraged Torrigiano that he struck him on the nose, and thus caused that disfigurement which is so conspicuous in all the portraits of Michelangelo. Soon after this Torrigiano visited Rome, and helped Pinturicchio in modelling the elaborate stucco decorations in the Apartamenti Borgia for Alexander VI. After some time spent as a hired soldier in the service of different states, Torrigiano was invited to England to execute the magnificent tomb for Henry VII. and his queen, which still exists in the lady chapel of Westminster Abbey. This appears to have been begun before the death of Henry VII. in 1509, but was not finished till 1517. The two effigies are well modelled, and have lifelike but not too realistic portraits. After this Torrigiano received the commission for the altar, retable and baldacchino which stood at the west, outside the screen of Henry VII.'s tomb. The altar had marble pilasters at the angles, two of which still exist, and below the *mensa* was a life-sized figure of the dead Christ in painted terra-cotta. The retable consisted of a large relief of the Resurrection. The baldacchino was of marble, with enrichments of gilt bronze; part of its frieze still exists, as do also a large number of fragments of the terra-cotta angels which surmounted the baldacchino and parts of the large figure of Christ. The whole of this work was destroyed by the Puritans in the 17th century.[1] Henry VIII. also commissioned Torrigiano to make him a magnificent tomb, somewhat similar to that of Henry VII., but one-fourth larger, to be placed in a chapel at Windsor; it was, however, never completed, and its rich bronze was melted by the Commonwealth, together with that of Wolsey's tomb. The indentures for these various works still exist, and are printed by Neale, *Westminster Abbey*, i. 54–59 (London, 1818). These interesting documents are written in English, and in them the Florentine is called "Peter Torrysany." For Henry VII.'s tomb he contracted to receive £1500, for the altar and its fittings £1000, and £2000 for Henry VIII.'s tomb. Other works attributed from internal evidence to Torrigiano are the tomb of Margaret of Richmond, mother of Henry VII., in the south aisle of his chapel, and a terra-cotta effigy in the chapel of the Rolls.

While these royal works were going on Torrigiano visited Florence in order to get skilled assistants. He tried to induce Benvenuto Cellini to come to England to help him, but Cellini refused partly from his dislike to the brutal and swaggering manners of Torrigiano, and also because he did not wish to live among "such beasts as the English." The latter part of Torrigiano's life was spent in Spain, especially at Seville, where, besides the painted figure of St Hieronymus in the museum, some terra-cotta sculpture by him still exists. His violent temper got him into difficulties with the authorities, and he ended his life in 1522 in the prisons of the Inquisition.

See Wilhelm Bode, *Die italienische Plastik* (Berlin, 1902).

TORRINGTON, ARTHUR HERBERT, Earl of (1647–1716), British admiral, was the son of a judge, Sir Edward Herbert (*c.* 1591–1657). He entered the navy in 1663, and served in the Dutch wars of the reign of Charles II., as well as against the Barbary pirates. From 1680 to 1683 he commanded in the Mediterranean. His career had been honourable, and he had been wounded in action. The known Royalist sentiments of his family combined with his reputation as a naval officer to point him out to the favour of the king, and James II. appointed him rear-admiral of England and master of the robes. The king no doubt counted on his support of the repeal of the Test Acts, as the admiral was member for Dover. Herbert refused, and was dismissed from his places. He now entered into communication with the agents of the prince of Orange, and promised to use his influence with the fleet to forward a revolution. After the acquittal of the seven bishops in 1688 he carried the invitation to William of Orange. The Revolution brought him ample amends for his losses. He was named first lord, and took the command of the fleet at home. In 1689 he was at sea attempting to prevent the French admiral Château-Renault (*q.v.*) from landing the troops sent by the king of France to the aid of King James in Ireland. Though he fought an action with

[1] An old drawing still exists showing this elaborate work; it is engraved in the *Hierurgia anglicana*, p. 267 (London, 1848). Many hundreds of fragments of this terra-cotta sculpture were found a few years ago hidden under the floor of the triforium in the abbey; they are unfortunately too much broken and imperfect to be fitted together.

the French in Bantry Bay on the 10th of May he failed to baffle Château-Renault, who had a stronger force. Being discontented with the amount of force provided at sea, he resigned his place at the admiralty, but retained his command at sea. In May 1689 he was created earl of Torrington. In 1690 he was in the Channel with a fleet of English and Dutch vessels, which did not rise above 56 in all, and found himself in front of the much more powerful French fleet. In his report to the council of regency he indicated his intention of retiring to the Thames, and losing sight of the enemy, saying that they would not do any harm to the coast while they knew his fleet to be "in being." The council, which knew that the Jacobites were preparing for a rising, and only waited for the support of a body of French troops, ordered him not to lose sight of the enemy, but rather than do that to give battle "upon any advantage of the wind." On the 10th of July Torrington, after consulting with his Dutch colleagues, made a half-hearted attack on the French off Beachy Head in which his own ship was kept out of fire, and severe loss fell on his allies. Then he retired to the Thames. The French pursuit was fortunately feeble (see TOURVILLE, COMTE DE) and the loss of the allies was comparatively slight. The indignation of the country was at first great, and Torrington was brought to a court martial in December. He was acquitted, but never again employed. Although twice married, he was childless when he died on the 14th of April 1716, his earldom becoming extinct. The unfavourable account of his moral character given by Dartmouth to Pepys is confirmed by Bishop Burnet, who had seen much of him during his exile in Holland. An attempt has been made in recent years to rehabilitate the character of Torrington, and his phrase "a fleet in being" has been widely used (see *Naval Warfare*, by Vice-Admiral P. H. Colomb).

See Charnock's *Biog. Nav.*, i. 258. The best account of the battle of Beachy Head is to be found in "The Account given by Sir John Ashby Vice-Admiral and Rear-Admiral Rooke, to the Lords Commissioners" (1691).

TORRINGTON, GEORGE BYNG, VISCOUNT (1663–1733), English admiral, was born at Wrotham, Kent. His father, John Byng, was compelled by pecuniary losses to sell his property and his son entered the navy as a king's letter boy (see NAVY) in 1678. He served in a ship stationed at Tangier, and for a time left the navy to enter one of the regiments of the garrison, but in 1683 he returned to the navy as lieutenant, and went to the East Indies in the following year. During the year 1688, he had an active share in bringing the fleet over to the prince of Orange, and by the success of the revolution his fortune was made. In 1702 he was appointed to the command of the "Nassau," and was at the taking and burning of the French fleet at Vigo, and the next year he was made rear-admiral of the red. In 1704 he served in the Mediterranean under Sir Cloudesley Shovel, and reduced Gibraltar. He was in the battle of Malaga, and for his gallantry received the honour of knighthood. In 1708 as admiral of the blue he commanded the squadron which baffled the attempt of the Old Pretender to land in Scotland. In 1718 he commanded the fleet which defeated the Spaniards off Cape Passaro and compelled them to withdraw from their invasion of Sicily. This commission he executed so well that the king made him a handsome present and sent him full powers to negotiate with the princes and states of Italy. Byng procured for the emperor's troops free access into the fortresses which still held out in Sicily, sailed afterwards to Malta, and brought out the Sicilian galleys and a ship belonging to the Turkey Company. By his advice and assistance the Germans retook the city of Messina in 1719, and destroyed the ships which lay in the basin—an achievement which completed the ruin of the naval power of Spain. To his conduct it was entirely owing that Sicily was subdued and the king of Spain forced to accept the terms prescribed him by the quadruple alliance. On his return to England in 1721 he was made rear-admiral of Great Britain, a member of the privy council, Baron Byng of Southill, in the county of Bedford and Viscount Torrington in Devonshire. He was also made one of the Knights Companions of the Bath upon the revival of that order in 1725. In 1727 George II. on his accession made him first lord of the admiralty, and his administration was distinguished by the establishment of the Royal Naval College at Portsmouth. He died on the 17th of January 1733, and was buried at Southill, in Bedfordshire. Two of his eleven sons, Pattee (1699–1747) and George (1701–1750), became respectively the 2nd and 3rd viscounts. The title is still held by the descendants of the latter.

See *Memoirs relating to Lord Torrington*, Camden Soc., new series 46, and *A True Account of the Expedition of the British Fleet to Sicily 1718–1720*, published anonymously, but known to be by Thomas Corbett of the admiralty in 1739. Forbin's *Memoirs* contain the French side of the expedition to Scotland in 1708.

TORRINGTON, a borough of Litchfield county, Connecticut, U.S.A., in the township of Torrington, on the Naugatuck river, about 25 m. W. of Hartford. Pop. (1900), 8360, of whom 2565 were foreign-born; (1910) 15,483; of the township, including the borough (1900) 12,453; (1910) 16,840. It is served by the New York, New Haven & Hartford railway and by an electric line connecting with Winsted. It has a public library (1865) with 15,000 volumes in 1909. There is a state armoury in the borough. Torrington is a prosperous manufacturing centre. In 1905 the value of the factory product was $9,674,124. The township of Torrington, originally a part of the township of Windsor, was first settled in 1734, and was separately incorporated in 1740. The site was covered by pine trees, which were much used for ship-building, and for this reason it was known as Mast Swamp. In 1751 a mill was erected, but there were few, if any, residences until 1800. In 1806 the settlement was known as New Orleans village. In 1813 members of the Wolcott family of Litchfield, impressed with the water-power, bought land and built a woollen mill, and the village that soon developed was called Wolcottville. Its growth was slow until 1864. In 1881 its name was changed to Torrington, and in 1887 the borough was incorporated.

See S. Orcutt's *History of Torrington* (Albany, 1878), and an article, "The Growth of Torrington," in the *Connecticut Magazine*, vol. ix., No. 1.

TORRINGTON (GREAT TORRINGTON), a market town and municipal borough in the South Molton parliamentary division of Devonshire, England, on the Torridge, 225 m. W. by S. of London by the London & South-Western railway. Pop. (1901), 3241. It stands on a hill overlooking the richly wooded valley of the Torridge, here crossed by three bridges. Glove manufactures on a large scale, with flour and butter making and leather dressing, are the staple industries. The town is governed by a mayor, 4 aldermen and 12 councillors. Area, 3592 acres.

Torrington (*Toritone*) was the site of very early settlement, and possessed a market in Saxon times. The manor was held by Brictric in the reign of Edward the Confessor, and in 1086 formed part of the Domesday fief of Odo Fitz Gamelin, which later constituted an honour with Torrington as its caput. In 1221 it appears as a mesne borough under William de Toritone, a descendant of Odo and the supposed founder of the castle, which in 1228 was ordered to be razed to the ground, but is said to have been rebuilt in 1340 by Richard de Merton. The borough had a fair in 1221, and returned two members to parliament from 1295 until exempted from representation at its own request in 1368. The government was vested in bailiffs and a commonalty, and no charter of incorporation was granted till that of Queen Mary in 1554, which instituted a governing body of a mayor, 7 aldermen and 18 chief burgesses, with authority to hold a court of record every three weeks on Monday; law-days and view of frankpledge at Michaelmas and Easter; a weekly market on Saturday, and fairs at the feasts of St Michael and St George. This charter was confirmed by Elizabeth in 1568 and by James I. in 1617. A charter from James II. in 1686 changed the style of the corporation to a mayor, 8 aldermen and 12 chief burgesses. In the 16th century Torrington was an important centre of the clothing trade, and in 1605 the town is described as very prosperous, with three fairs, and a great market "furnished from far on every quarter, being the most convenient place for occasions of king or county in those parts." The Saturday market is still maintained, but the fairs have been altered to the third Saturday in March and the first Thursday in May. In 1643 Colonel Digby took up his position at Torrington and put to flight a contingent of parliamentary troops; but in 1646 the town was besieged by Sir Thomas Fairfax and finally forced to surrender. The borough records were destroyed by fire in 1724.

See *Victoria County History: Devonshire*; F. T. Colby, *History of Great Torrington* (1878).

TORSTENSSON, LENNART, Count (1603–1651), Swedish soldier, son of Torsten Lennartsson, commandant of Elfsborg, was born at Forstena in Vestergötland. At the age of fifteen he became one of the pages of the young Gustavus Adolphus and served during the Prussian campaigns of 1628–29. In 1629 he was set over the Swedish artillery, which under his guidance materially contributed to the victories of Breitenfeld (1631) and Lech (1632). The same year he was taken prisoner at Alte Veste and shut up for nearly a year at Ingolstadt. Under Banér he rendered distinguished service at the battle of Wittstock (1636) and during the energetic defence of Pomerania in 1637–38, as well as at the battle of Chemnitz (1638) and in the raid into Bohemia in 1639. Illness compelled him to return to Sweden in 1641, when he was made a senator. The sudden death of Banér in May 1641 recalled Torstensson to Germany as generalissimo of the Swedish forces and governor-general of Pomerania. He was at the same time promoted to the rank of field marshal. The period of his command (1641–1645) forms one of the most brilliant chapters in the military history of Sweden. In 1642 he marched through Brandenburg and Silesia into Moravia, taking all the principal fortresses on his way. On returning through Saxony he well nigh annihilated the imperialist army at the second battle of Breitenfeld (Oct. 23, 1642). In 1643 he invaded Moravia for the second time, but was suddenly recalled to invade Denmark, when his rapid and unexpected intervention paralysed the Danish defence on the land side, though Torstensson's own position in Jutland was for a time precarious owing to the skilful handling of the Danish fleet by Christian IV. In 1644 he led his army for the third time into the heart of Germany and routed the imperialists at Jüterbog (Nov. 23). At the beginning of November 1645 he broke into Bohemia, and the brilliant victory of Jankow (Feb. 24, 1645) laid open before him the road to Vienna. Yet, though one end of the Danube bridge actually fell into his hands, his exhausted army was unable to penetrate any farther and, in December the same year, Torstensson, crippled by gout, was forced to resign his command and return to Sweden. In 1647 he was created a count. From 1648 to 1651 he ruled all the western provinces of Sweden, as governor-general. On his death at Stockholm (April 7, 1651) he was buried solemnly in the Riddarholmskyrka, the Pantheon of Sweden. Torstensson was remarkable for the extraordinary and incalculable rapidity of his movements, though very frequently he had to lead the army in a litter, as his bodily infirmities would not permit him to mount his horse. He was also the most scientific artillery officer and the best and most successful engineer in the Swedish army.

His son, Senator Count Anders Torstensson (1641–1686), was from 1674 to 1681 governor-general of Esthonia. The family became extinct on the sword-side in 1727.

See J. W. de Peyster, *History of the Life of L. Torstensson* (Poughkeepsie, 1855); J. Feil, *Torstensson before Vienna* (trans. by de Peyster, New York, 1885); Gustavus III., *Eulogy of Torstensson* (trans. by de Peyster, New York, 1872). (R. N. B.)

TORT (Fr. for wrong, from Lat. *tortus*, twisted, participle of *torquere*), the technical term, in the law of England, of those dominions and possessions of the British Empire where the common law has been received or practically adopted in civil affairs, and of the United States, for a civil wrong, *i.e.* the breach of a duty imposed by law, by which breach some person becomes entitled to sue for damages. A tort must, on the one hand, be an act which violates a general duty. The rule which it breaks must be one made by the law, not, as in the case of a mere breach of contract, a rule which the law protects because the parties have made it for themselves. On the other hand, a tort is essentially the source of a private right of action. An offence which is punishable, but for which no one can bring a civil action, is not a tort. It is quite possible for one and the same act to be a tort and a breach of contract, or a tort and a crime; it is even possible in one class of cases for the plaintiff to have the option—for purposes of procedural advantage—of treating a real tort as a fictitious contract; but there is no necessary or general connexion. Again, it is not the case that pecuniary damages are always or necessarily the only remedy for a tort; but the right to bring an action in common law jurisdiction, as distinct from equity, matrimonial or admiralty jurisdiction, with the consequent right to damages, is invariably present where a tort has been committed.

This technical use of the French word *tort* (which at one time was near becoming a synonym of *wrong* in literary English) is not very ancient, and anything like systematic treatment of the subject as a whole is very modern. Since about the middle of the 19th century there has been a current assumption that all civil causes of action must be founded on either contract or tort; but there is no historical foundation for this doctrine, though modified forms of the action of trespass—actions *in consimili casu*, or "on the case" in the accustomed English phrase—did in practice largely supplant other more archaic forms of action by reason of their greater convenience. The old forms were designed as penal remedies for manifest breach of the peace or corruption of justice; and traces of the penal element remained in them long after the substance of the procedure had become private and merely civil. The transition belongs to the general history of English law.

In England the general scope of the law of torts has never been formulated by authority, the law having in fact been developed by a series of disconnected experiments with the various forms of action which seemed from time to time to promise the widest and most useful remedies. But there is no doubt that the duties enforced by the English law of torts are broadly those which the Roman institutional writers summed up in the precept *Alterum non laedere*. Every member of a civilized commonwealth is entitled to require of others a certain amount of respect for his person, reputation and property, and a certain amount of care and caution when they go about undertakings attended with risk to their neighbours. Under the modern law, it is submitted, the question arising when one man wilfully or recklessly harms another is not whether some technical form of action can be found in which he is liable, but whether he can justify or excuse himself. This view, at any rate, is countenanced by a judgment of the Supreme Court of the United States delivered in 1904. If it be right, the controverted question whether conspiracy is or is not a substantive cause of action seems to lose most of its importance. Instead of the doubtful proposition of law that some injuries become unlawful only when inflicted by concerted action, we shall have the plain proposition of fact that some kinds of injury cannot, as a rule, be inflicted by one person with such effect as to produce any damage worth suing for.

The precise amount of responsibility can be determined only by full consideration in each class of cases. It is important to observe, however, that a law of responsibility confined to a man's own personal acts and defaults would be of next to no practical use under the conditions of modern society. What makes the law of torts really effective, especially with regard to redress for harm suffered by negligence, is the universal rule of law that every one is answerable for the acts and defaults of his servants (that is, all persons acting under his direction and taking their orders from him or some one representing him) in the course of their employment. The person actually in fault is not the less answerable, but the remedy against him is very commonly not worth pursuing. But for this rule corporations could not be liable for any negligence of their servants, however disastrous to innocent persons, except so far as it might happen to constitute a breach of some express undertaking. We have spoken of the rule as universal, but, in the case of one servant of the same employer being injured by the default of another, an unfortunate aberration of the courts, which started about two generations ago from small beginnings, was pushed to extreme results, and led to great hardship. A partial remedy was applied in 1880 by the Employers' Liability Act; and in 1897 a much bolder step was taken by the Workmen's Compensation Act (superseded by a more comprehensive act in 1906). But, as the common law and the two acts (which proceed on entirely different principles) cover different fields, with a good deal of overlapping, and the acts are full of complicated provisos and exceptions, and contain very special provisions as to procedure, the improvement in substantial justice has been bought, so far, at the price of great confusion in the form of the law, and considerable difficulty in ascertaining what it is in any but the most obvious cases. The Workmen's Compensation Act includes cases of pure accident, where there is no fault at all, or none that can be proved, and therefore goes beyond the reasons of liability with which the law of torts has to do. In fact, it establishes a kind of compulsory insurance, which can be justified only on wider grounds of policy. A novel and extraordinary exception to the rule of responsibility for agents was made in the case of trade combinations by the Trade Disputes Act 1906. This has no interest for law as a science.

There are kinds of cases, on the other hand, in which the law, without aid from legislation, has imposed on occupiers and other persons in analogous positions a duty stricter than that of being answerable for themselves and their servants. Duties of this kind have been called " duties of insuring safety." Generally they extend to having the building, structure, or works in such order, having regard to the nature of the case, as not to create any danger to persons lawfully frequenting, using, or passing by them, which the exercise of reasonable care and skill could have avoided; but in some cases of " extra-hazardous " risk, even proof of all possible diligence—according to English authority, which is not unanimously accepted in America—will not suffice. There has lately been a notable tendency to extend these principles to the duties incurred towards the public by local authorities who undertake public works. Positive duties created by statute are on a similar footing, so far as the breach of them is capable of giving rise to any private right of action.

The classification of actionable wrongs is perplexing, not because it is difficult to find a scheme of division, but because it is easier to find many than to adhere to any one of them. We may start either from the character of the defendant's act or omission, with regard to his knowledge, intention and otherwise; or from the character of the harm suffered by the plaintiff. Whichever of these we take as the primary line of distinction, the results can seldom be worked out without calling in the other. Taking first the defendant's position, the widest governing principle is that, apart from various recognized grounds of immunity, a man is answerable for the " natural and probable " consequences of his acts; *i.e.* such consequences as a reasonable man in his place should have foreseen as probable. Still more is he answerable for what he did actually foresee and intend. Knowledge of particular facts may be necessary to make particular kinds of conduct wrongful. Such is the rule in the case of fraud and other allied wrongs, including what is rather unhappily called " slander of title," and what is now known as " unfair competition " in the matter of trade names and descriptions, short of actual piracy of trade-marks. But where an absolute right to security for a man's person, reputation or goods is interfered with, neither knowledge nor specific intention need be proved. In these cases we trespass altogether at our peril. It is in general the habit of the law to judge acts by their apparent tendency, and not by the actor's feelings or desires. I cannot excuse myself by good motives for infringing another man's rights, whatever other grounds of excuse may be available; and it is now settled conversely, though after much doubt, that an act not otherwise unlawful is not, as a rule, made unlawful by being done from an evil motive. This rule was known some time ago to apply to the exercise of rights of property, and such speculative doubt as remained was removed by the decision of the House of Lords in the leading case of *Allen* v. *Flood* (1898, A.C. 1). We now know that it applies to the exercise of all common rights. The exceptions are very few, and must be explained by exceptional reasons. Indeed, only two are known to the present writer—malicious prosecution, and the misuse of a " privileged occasion " which would justify the communication of defamatory matter if made in good faith. In each case the wrong lies in the deliberate perversion of a right or privilege allowed for the public good, though the precise extent of the analogy is not certain at present.[1] It must be remembered, however, that the presence or absence of personal ill will, and the behaviour of the parties generally, may have an important effect, when liability is proved or admitted, in mitigating or aggravating the amount of damages awarded by juries and allowed by the court to be reasonable. It may likewise be noted, by way of caution, that some problems of criminal law, with which we are not here concerned, require more subtle consideration. However, it is hardly ever safe to assume that the bounds of civil and criminal liability will be found coextensive. Perhaps we may go so far as to say that a man is neither civilly nor criminally liable for a mere omission (not being disobedience to a lawful command which he was bound to obey), unless he has in some way assumed a special duty of doing the act omitted.

We have already had to mention the existence of grounds of immunity for acts that would otherwise be wrongful. Such grounds there must be if the law is to be enforced and justice administered at all, and if the business of life is to be carried on with any freedom. Roughly speaking, we find in these cases one of the following conditions: Either the defendant was executing a lawful authority; or he was justified by extraordinary necessity; or he was doing something permitted by legislation for reasons of superior utility, though it may produce damage to others, and either with or without special provisions for compensating damage; or he was exercising a common right in matters open to free use and competition; or the plaintiff had, by consent or otherwise, disabled himself from having any grievance. Pure accident will hardly seem to any one who is not a lawyer to be a special ground of exemption, the question being rather how it could ever be supposed to be a ground of liability. But it was supposed so by many lawyers down to recent times; the reason lying in a history of archaic ideas too long to be traced here. Exercise of common rights is the category where most difficulty arises. Here, in fact, the point at which a man's freedom is limited by his neighbour's has to be fixed by a sense of policy not capable of formal demonstration.

As Justice Holmes of the Supreme Court of the United States has said, we allow unlimited trade competition (so long as it is without fraud) though we know that many traders must suffer, and some may be ruined by it, because we hold that free competition is worth more to society than its costs. A state with different economic foundations might have a different law on this, as on many other points. This freedom extends not only to the exercise of one's calling, but to choosing with whom and under what conditions one will exercise it. Also the law will not inquire with what motives a common right is exercised; and this applies to the ordinary rights of an owner in the use of his property

[1] It was formerly supposed that an action by a party to a contract against a third person for procuring the other party to break his contract was within the same class, *i.e.* that malice must be proved. But since *Allen* v. *Flood*, and the later decision of the House of Lords in *Quinn* v. *Leathem* (1901, A.C. 495), this view seems untenable. The ground of action is the intentional violation of an existing legal right; which, however, since 1906, may be practised with impunity in the United Kingdom " in contemplation or furtherance of a trade dispute ": Trade Disputes Act, § 3.

as well as to the right of every man to carry on his business.[1] Owners and occupiers of immovable property are bound, indeed, to respect one another's convenience within certain limits. The maxim or precept *Sic utere tuo ut alienum non laedas* does not mean that I must not use my land in any way which can possibly diminish the profit or amenity of my neighbour's. That would be false. It is a warning that both his rights and mine extend beyond being free from actual unlawful entry, and that if either of us takes too literally the more popular but even less accurate maxim, "Every man may do as he will with his own," he will find that there is such a head of the law as nuisance.

From the point of view of the plaintiff, as regards the kind of damage suffered by him, actionable wrongs may be divided into four groups. We have some of a strictly personal kind; some which affect ownership and rights analogous to ownership; some which extend to the safety, convenience and profit of life generally—in short, to a man's estate in the widest sense; and some which may, according to circumstances, result in damage to person, property or estate, any or all of them. Personal wrongs touching a man's body or honour are assault, false imprisonment, seduction or "enticing away" of members of his family. Wrongs to property are trespass to land or goods, "conversion" of goods (*i.e.* wrongful assumption of dominion over them), disturbance of easements and other individual rights in property not amounting to exclusive possession. Trespass is essentially a wrong to possession; but with the aid of actions "on the case" the ground has been practically covered. Then there are infringements of incorporeal rights which, though not the subject of trespass proper, are exclusive rights of enjoyment and have many incidents of ownership. Actions, in some cases expressly given by statute, lie for the piracy of copyright, patents and trade marks. Wrongs to a man's estate in the larger sense above noted are defamation (not a strictly personal wrong, because according to English common law the temporal damage, not the insult, is, rightly or wrongly, made the ground of action); deceit, so-called "slander of title" and fraudulent trade competition, which are really varieties of deceit; malicious prosecution; and nuisance, which, though most important as affecting the enjoyment of property, is not considered in that relation only. Finally, we have the results of negligence and omission to perform special duties regarding the safety of one's neighbours or customers, or of the public, which may affect person, property, or estate generally.

The law of wrongs is made to do a great deal of work which, in a system less dependent on historical conditions, we should expect to find done by the law of property. We can claim or reclaim our movable goods only by complaining of a wrong done to our possession or our right to possess. There is no direct assertion of ownership like the Roman *vindicatio*. The law of negligence, with the refined discussions of the test and measure of liability which it has introduced, is wholly modern; and the same may be said of the present working law of nuisance, though the term is of respectable antiquity. Most recent of all is the rubric of "unfair competition," which is fast acquiring great importance.

It will be observed that the English law of torts answers approximately in its purpose and contents to the Roman law of obligations *ex delicto* and *quasi ex delicto*. When we have allowed for the peculiar treatment of rights of property in the common law, and remembered that, according to one plausible theory, the Roman law of possession itself is closely connected in its origin with the law of delicts, we shall find the correspondence at least as close as might be expected a priori. Nor is the correspondence to be explained by borrowing, for this branch of the common law seems to owe less to the classical Roman or medieval canon law than any other. Some few misunderstood Roman maxims have done considerable harm in detail, but the principles have been worked out in all but complete independence.

A list of modern books and monographs will be found at the end of the article on "Torts" by the present writer in the *Encyclopaedia of the Laws of England* (2nd ed.). Among recent editions of works on the law of torts and new publications the following may be mentioned here: Addison, by W. E. Gordon and W. H. Griffith (8th ed., 1906); Clerk and Lindsell, by Wyatt Paine (4th ed., 1906); Pollock (8th ed., 1908); Salmond, *The Law of Torts* (2nd ed., 1910). In America: Burdick, *The Law of Torts* (1905); Street, *The Foundations of Legal Liability* (1906), 3 vols. of which vol. i. is on Tort. (F. Po.)

[1] The rule that a man's motives for exercising his common rights are not examinable involves the consequence that advising or procuring another, who is a free agent, to do an act of this kind can, a fortiori, not be an actionable wrong at the suit of a third person who is damnified by the act, and that whatever the adviser's motives may be. This appears to be included in the decision of the House of Lords in *Allen* v. *Flood*. That decision, though not binding in any American court, is approved and followed in most American jurisdictions. It is otherwise where a system of coercion is exercised on a man's workmen or customers in order to injure him in his business. The extension of immunity to such conduct would destroy the value of the common right which the law protects: *Quinn* v. *Leathem*. The coercion need not be physical, and the wrong as a whole may be made up of acts none of which taken alone would be a cause of action. In this point there is nothing novel, for it is so in almost every case of nuisance. Conspiracy is naturally a frequent element in such cases, but it does not appear to be necessary; if it were, millionaires and corporations might exceed the bounds of lawful competition with impunity whenever they were strong enough. The reasons given in *Quinn* v. *Leathem* are many and various, but the decision is quite consistent with *Allen* v. *Flood*. However, the Trade Disputes Act will probably have its intended effect of reducing the law on this head to relative insignificance in England.

TORTOISE. Of the three names generally used for this order of reptiles, viz. tortoise, turtle and terrapin, the first is derived from the Old French word *tortis*, *i.e.* twisted, and was probably applied first to the common European species on account of its curiously bent forelegs. Turtle is believed to be a corruption of the same word, but the origin of the name terrapin is unknown: since the time of the navigators of the 16th century it has been in general use for fresh-water species of the tropics, and especially for those of the New World. The name tortoise is now generally applied to the terrestrial members of this group of animals, and that of turtle to those which live in the sea or pass a great part of their existence in fresh water. They constitute one of the orders of reptiles, the Chelonia: toothless reptiles, with well developed limbs, with a dorsal and a ventral shell composed of numerous bony plates, large firmly fixed quadrates, a longitudinal anal opening and an unpaired copulatory organ.

The whole shell consists of the dorsal, more or less convex carapace and the ventral plastron, both portions being joined laterally by the so-called bridge. The carapace is (with the exception of *Sphargis*) formed by dermal ossifications which are arranged in regular series, viz. a median row (1 nuchal, mostly 8 neurals and 1–3 supracaudal or pygal plates), a right and left row of costal plates which surround and partly replace the ribs, and a considerable number (about 11 pairs) of marginal plates. The plastron consists of usually 9, rarely 11, dermal bones, viz. paired epi-, hyo-, hypo- and xiphi-plastral plates and the unpaired endo-plastral; the latter is homologous with the interclavicle, the epi-plastra with the clavicles, the rest with so-called abdominal ribs of other reptiles.

In most Chelonians the bony shell is covered with a hard epidermal coat, which is divided into large shields, commonly called "tortoiseshell." These horny shields or scutes do not correspond in numbers and extent with the underlying bones, although there is a general, vague resemblance in their arrangement; for instance, there is a neural, a paired costal and a paired marginal series. The terminology may be learned from the accompanying illustrations (figs. 1 and 2).

The integuments of the head, neck, tail and limbs are either soft and smooth or scaly or tubercular, frequently with small osseous nuclei.

All the bones of the skull are suturally united. The dentary portion of the mandible consists of one piece only, both halves being completely fused together. The pectoral arch remains separate in the median line; it consists of the coracoids, which slope backwards, and the scapulae, which stand upright and often abut against the inside of the first pair of costal plates. Near the glenoid cavity for the humerus arises from the scapula a long process which is directed transversely towards its fellow; it represents the acromial process of other vertebrates, although so much enlarged, and is neither the precoracoid, nor the clavicle, as stated by the thoughtless. The tail is still best developed in the Chelydridae, shortest in the Trionychoidea. Since it contains the large copulatory organ, it is less reduced in the males. No Chelonians possess the slightest traces of teeth, but their jaws are provided with horny sheaths, with hard and sharp edges, forming a beak.

The number of Chelonians known at present may be estimated at about 200, the fresh-water species being far the most numerous, and are abundant in well-watered districts of the tropical and sub-tropical zones. Their number and variety decrease beyond the tropics, and in the north they disappear entirely about the 50th parallel in the western and about the 56th in the eastern hemisphere, whilst in the southern hemisphere the terrestrial forms seem to advance to 36° S. only. The marine turtles, which are spread over the whole of the equatorial and sub-tropical seas, sometimes stray beyond those limits. As in other orders

of reptiles, the most specialized and the largest forms are restricted to the tropics (with the exception of *Macroclemmys*); but, unlike lizards or snakes, Chelonians are unable to exist in sterile districts or at great altitudes.

They show a great divergence in their mode of life—some living constantly on land, others having partly terrestrial partly aquatic habits, others again rarely leaving the water or the sea. The first-mentioned, the land tortoises proper, have short club-shaped feet with blunt claws, and a very convex, heavy, completely ossified shell. In the fresh-water forms the joints of the limb bones are much more mobile, the digits distinct, armed with sharp claws, and united by a membrane or web; their shell is less convex, and is flattened, and more or less extensive areas may remain unossified, or transparent windows are formed with age, for instance in *Batagur*. As a rule, the degree of development of the interdigital web and of convexity of the shell indicates the prevalence of aquatic or terrestrial habits of a species of terrapin. Finally, the marine turtles have paddle-shaped limbs resembling those of Cetaceans.

Land tortoises are sufficiently protected by their carapace, and therefore have no need of any special modification of structure by means of which their appearance would be assimilated to the surroundings and thus give them additional security from their enemies. These, however, are few in number. On the other hand, among the carnivorous terrapins and fresh-water turtles instances of protective resemblance are not scarce, and may even attain to a high degree of specialization, as in *Chelys*, the matamata. The colours of land tortoises are generally plain, or in yellow and brown patterns, whilst those of many terrapins are singularly varied, bright and beautiful, especially in the very young, but all this beauty is lost in the adult of many species.

Chelonians are diurnal animals; only a few are active during the night, habitually or on special occasions, as, for instance, during oviposition. Land tortoises are slow in all their movements, but all kinds living in water can execute rapid motions, either to seize their prey or to escape from danger. All Chelonians are stationary, residing throughout the year in the same locality, with the exception of the marine turtles, which periodically migrate to their breeding-stations. Species inhabiting temperate regions hibernate.

Land tortoises, a few terrapins, and some of the marine turtles are herbivorous, the others carnivorous, their prey consisting chiefly of fish, frogs, molluscs, and other small aquatic animals; some, *e.g. Clemmys insculpta* and *Cistudo carolina*, have a mixed vegetable and animal diet.

All Chelonians are oviparous, and the eggs are generally covered with a hard shell, mostly elliptical, rarely quite round, as in the case of the marine turtles. The various modifications, and also the not uncommon individual variations, in the composition of the carapace plates and the number and disposition of the shields, are very significant. They show an unmistakable tendency towards reduction in numbers, a concentration and simplification of the shell and its covering shields. We can to a certain extent reconstruct a generalized ancestral tortoise and thereby narrow the wide gap which separates the Chelonia from every other reptilian order. The early Chelonians possessed most likely more than five longitudinal dorsal rows of plates. The presence of several small supramarginal shields in *Macroclemmys* may be an indication that the total number of longitudinal rows was originally at least seven. The number of transverse rows, both of plates and shields, was also greater. We can account for at least twelve median plates and as many pairs of marginals, but for only eight median and eight pairs of costal shields (individual variations observed in *Thalassochelys*). It stands to reason that originally each trunk metamere had its full complement of plates and shields; consequently that about twelve trunk metameres partook in the formation of the shell, which, with subsequent shortening and broadening of the trunk, has undergone considerable concentration and reduction, a process which has reduced the costal plates to seven pairs in the American species of *Trionyx*, has completely abolished the neural plates of some Chelydidae, and has brought down the costal shields to four pairs in the majority of recent Chelonians. In several species of *Testudo* the little nuchal shield is suppressed, thereby reducing the unpaired median shields to five. The complete absence of shields in the *Trionychidae* and in *Carettochelys* is also due to a secondary process, which, however, has proceeded in a different way.

Classification of Chelonia.

H. Stannius in 1854 clearly separated the Trionychoidea from the rest. E. D. Cope, in 1870, distinguished between Pleurodira and Cryptodira according to whether the neck, δέρη or δειρή, is bent sidewards, or hidden by being withdrawn in an S-shaped curve in a vertical plane; he also separated *Sphargis* as Athecae from all the other Chelonians, for which L. Dollo, in 1886, proposed the term Thecophora. These terms are most unfortunate, misleading. Athecae (from θήκη, shell) has reference to the absence of a horny shell-covering in the leathery turtle; but since the same character applies to Trionychoidea and to *Carettochelys*, nobody can guess that the term *Athecae* in Dollo's sense refers to the fact that the shell of the leathery turtle is not homologous with the typical shell or θήκη of the other Chelonians. The grouping of the latter into families recognizable by chiefly internal, skeletal characters has been effected by G. A. Boulenger. For practical purposes the following "key" is preferable to those taxonomic characters which are mentioned in the descriptions of the different families. The relationships between them may be indicated as follows:—

- Chelonia
  - Athecae . . . . . Sphargidae
  - Thecophora
    - Pleurodira
      - Pelomedusidae
      - Chelydidae
      - Carettochelydidae
    - Cryptodira
      - Chelydridae—Dermatemydidae-Cinosternida
      - Platysternidae
      - Testudinidae
      - Chelonidae
    - Trionychoidea

Key to the Families of Chelonia.

Shell covered with horny shields.	
Digits distinct, with five or four claws.	
Pectoral shields separated from the marginals by inframarginals.	
Tail long and crested. Plastron small and cruciform	Chelydridae
Tail long, covered with rings of shields. Plastron large	Platysternidae
Tail short	Dermatemydidae, Cinosternidae
Pectoral shields in contact with the marginals.	
Plastral shields 11 or 12, without an intergular.	
Neck retractile in an S-shaped vertical curve	Testudinidae
Plastral shields 13, an intergular being present.	
Neck bending sideways under the shell	Chelydidae, Pelomedusidae
Limbs paddle-shaped, with one or two claws	Chelonidae
Shell without horny shields, covered with soft leathery skin.	
Digits distinct, broadly webbed, but with only three claws	Trionychoidea
Limbs paddle-shaped.	
Shell composed of regular series of bony plates. Two claws	Carettochelydidae
Shell composed of very many small plates arranged like mosaic. No claws . .	Sphargidae.

Sub-order I. Athecae.—The shell consists of a mosaic of numerous small polygonal osseous plates and is covered with leathery skin without any horny shields. The limbs are transformed into paddles, without claws. Marine. Sole representative *Sphargis* or *Dermatochelys coriacea*, the leathery turtle or luth; it is the largest of living Chelonians, surpassing 6 ft. in length, has a wide distribution over all the intertropical seas, but is very rare everywhere; a few stragglers have appeared as far north as the coasts of Long Island, and those of Great Britain, Holland and France. It is a curious fact that only adults and young, but none of intermediate size, happen to be known. This creature shows many important features. The vertebrae and ribs are not fused with, but remain free from, the carapace, and this is fundamentally different from and not homologous with that of other Chelonians. O. P. Hay has suggested that the mosaic polygonal components of the shell of *Sphargis* are, so to speak, an earlier generation of osteodermal plates than the fewer and larger plates of the Thecophora, which in them fuse with the neural arches and the ribs. *Sphargis* has, however, the later category in the plastron and in its first neural or nuchal plate. If this suggestion is correct, this turtle has either lost or perhaps never had developed the horny shields. The many mosaic plates comprise larger plates which form an unpaired median, two pairs of other dorsal, a lateral and three pairs of ventral series or ridges; thirteen, or when the inner ventral pair fuses, twelve pairs in all.

The skull, excellently studied by J. F. van Bemmelen, much resembles that of *Chelone*, but so-called epipterygoids are absent; further, the pterygoids, instead of sending lateral arms to the jugals and maxillaries, are widely separated from these bones by the palatines, and these do not at all ventrally roof over the choanae. The position of *Sphargis* in the system is still a moot question. G. A. Boulenger looks upon it as the sole remnant of a primitive group in opposition to all the other recent Chelonia; G. Baur considered it the most specialized descendant of the Chelonidae, a

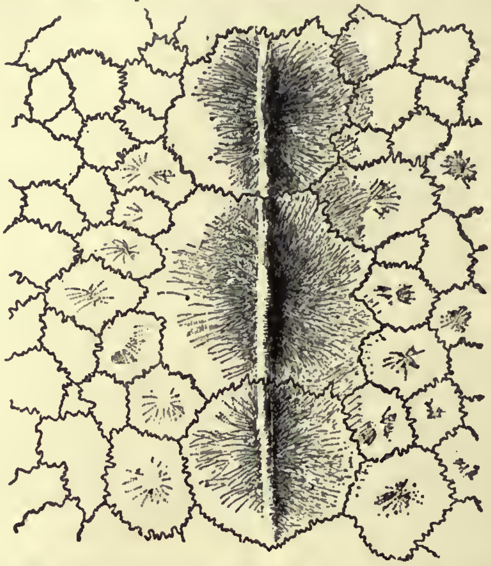

Fig. 3.—A portion of the Osseous Plates of the Carapace of *Sphargis coriacea*, showing three large keeled plates of one of the longitudinal ridges of the carapace, with a number of the small irregular plates on either side of them.

view which has been supported by W. Dames, E. C. Case, and to a certain extent by J. F. van Bemmelen. For literature, &c., see L. Dollo, *Bull. S. R. Bruxelles* (Février 4, 1901).

Sub-order II. Thecophora.—The bony shell is composed of several longitudinal series of plates (on the dorsal side a median or neural, a paired lateral or costal series, and marginal plates). With few exceptions this shell is covered with large horny scutes or shields.

Super-family 1. Cryptodira.—The neck, if retractile, bends in an S-shaped curve in a vertical plane. The pelvis is not fused with the shell, and this is covered with large horny shields, except in *Carettochelys*.

Family 1. Chelydridae.—The plastron is rather narrow, and cross-shaped; the bridge is very narrow and is covered by a pair of shields, the displaced abdominals, which are separated from the marginals by a few inframarginals. The limbs, neck and head are so stout that they cannot completely be withdrawn into the shell. The tail is very long. Only two genera with three species, confined to America. *Chelydra serpentina*, the "snapping turtle," ranging from the Canadian lakes through the United States east of the Rockies; closely allied is *C. rossignoni* of Central America and Ecuador. *Macroclemmys temmincki*, the "alligator turtle," is the largest known fresh-water Chelonian, its shell growing to a length

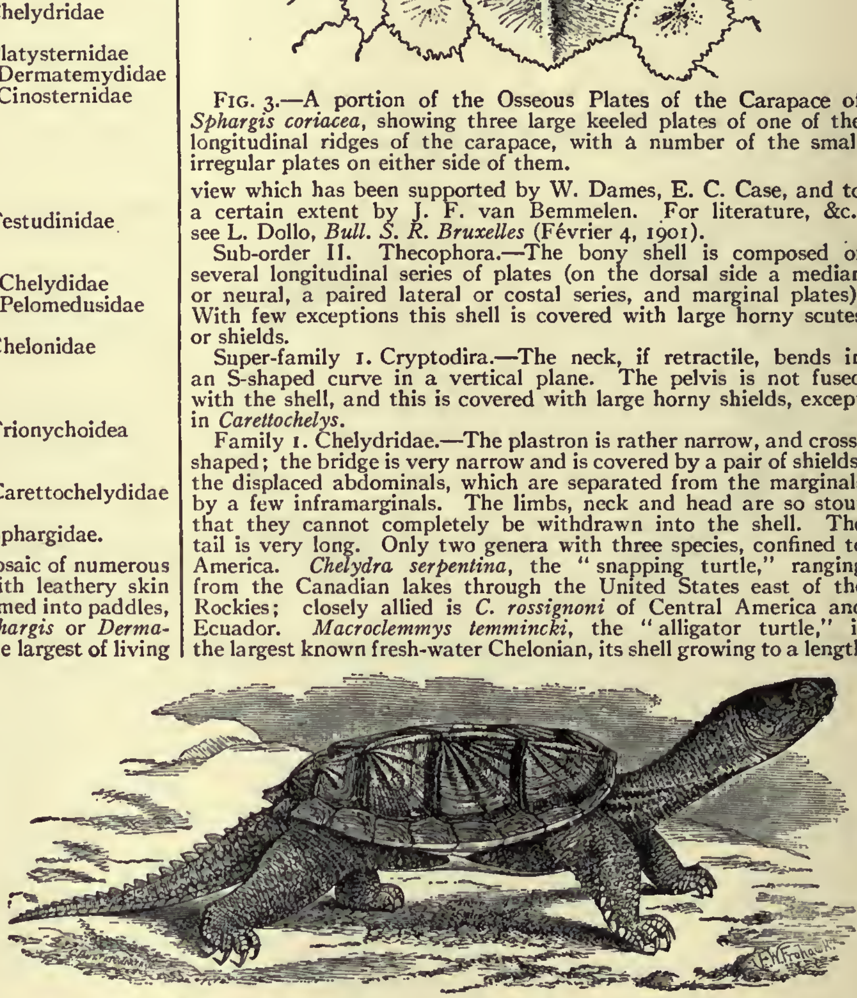

Fig. 4.—The Snapping Turtle (*Chelydra serpentina*).

of 3 ft. It is characterized by the three series of strong prominent keels along the back; it inhabits the whole basin of the Mississippi and Missouri rivers.

Family 2. Dermatemydidae.—The pectoral shields are widely separated from the marginals by inframarginals, the gulars are small or absent, and the tail is extremely short. Only a few species, in Central America. The plastron is composed of nine plates. The nuchal plate has a pair of rib-like processes like those of the Chelydridae. One or more of the posterior costal plates meet in the middle line. The shell of these aquatic, broadly web-fingered tortoises, is very flat and the covering shields are thin. They feed upon leaves, grass and especially fruit. *Staurotypus*, *e.g.* *salvini* with 23, *Dermatemys*, *e.g. mawi*, with 25 marginal shields.

Family 3. Cinosternidae.—Closely allied to the two previous families from which *Cinosternum*, the only genus, differs chiefly by the absence of the endo-plastral plate. Inframarginals are present. The nuchal plate has a pair of rib-like processes. The neural plates are interrupted by the meeting of several pairs of the costal plates. Twenty-three marginal shields. In some species the skin of the legs and neck is so baggy that these parts slip in, the skin rolling off, when such a turtle withdraws into its shell. In some the plastron is hinged and the creature can shut itself up tightly, *e.g.* *C. leucostoma* of Mexico; in others the plastron leaves gaps, or it is narrow and without hinges, *e.g. C. odoratum*, the mud turtle or stinkpot terrapin of the eastern half of North America. About a dozen species, mostly Central American.

Family 4. Platysternidae.—*Platysternum megacephalum*, the only species, from Burma to southern China. The total length of these thick-headed, very long-tailed turtles is about 1 ft., only 5 in. belonging to the shell. The plastron is large, oblong, not cruciform, composed of nine plates. The nuchal is devoid of rib-like processes. A unique arrangement is that the jugals are completely shut off from the orbits owing to the meeting of the post-frontals with the maxillaries.

Family 5. Testudinidae.—The shell is always covered with well-developed shields; those which cover the plastral bridge are in direct contact with the marginals. The plastron is composed of nine bones. The digits have four or five claws. The neck is completely retractile.

This family contains the majority of tortoises, divided into as many as 20 genera. These, starting with *Emys* as the least specialized, can be arranged in two main diverging lines, one culminating in the thoroughly aquatic *Batagur*, the other in the exclusively terrestrial forms. *Emys*, with the plastron movably united to the carapace; with well-webbed limbs, amphibious. *E. orbicularis* or *europaea* was, towards the end of the Pleistocene period, distributed over a great part of middle Europe, remains occurring in the peat of England, Belgium, Denmark and Sweden; it is now withdrawing eastwards, being restricted in Germany to isolated localities east of Berlin, but it reoccurs in Poland and Russia, whence it extends into western Asia; it is common in south Europe. The other species, *E. blandingi*, lives in Canada and the north-eastern states of the Union. *Clemmys* with the plastron immovably united to the carapace; temperate holarctic region, *e.g. C. caspica*, *C. leprosa* in Spain and Morocco; *C. insculpta*, in north-east America. *Malacoclemmys* with a few species in North America, *e.g. M. terrapin*, the much prized "diamond-back." *Chrysemys* with many American species, *e.g. Ch. picta*, the "painted terrapin" and *C. concinna*, most of them very handsomely coloured and marked when still young. *Batagur* and *Kachuga* in the Indian sub-region.

Cistudo carolina, the box tortoise of North America, with the plastron divided into an anterior and a posterior movable lobe, so that the creature can shut itself up completely. Although essentially by its internal structure a water tortoise, it has become absolutely terrestrial in habits, and herewith agree the high-backed instead of depressed shell, the short webless fingers and its general coloration. It has a mixed diet. The eyes of the males are red, those of the females are brown. From Long Island to Mexico. *Cinixys*, *e.g. belliana* of tropical Africa, has the posterior portion of the carapace movably hinged. *Pyxis arachnoides* of Madagascar has the front-lobe of the plastron hinged.

Testudo, the main genus, with about 40 species, is cosmopolitan in tropical and sub-tropical countries, with the exception of the whole of the Australian and Malay countries; most of the species are African. *T. graeca*, in Mediterranean countries and islands. *T. marginata* in Greece with the posterior margin of the carapace much flanged or serrated, and *T. ibera* or *mauritanica* from Morocco to Persia; both differ from *T. graeca* by an unpaired supracaudal, marginal shield, and by the possession of a strong, conical, horny tubercle on the hinder surface of the thigh. With age the posterior portion of the plastron develops a transverse ligamentous hinge. *T. polyphemus*, the "gopher" of southern United States, lives in pairs in self-dug burrows. *T. tabulata* is one of the few South American terrestrial tortoises.

Of great interest are the so-called gigantic land tortoises. In former epochs truly gigantic species of the genus *Testudo* had a wide and probably more continuous distribution. There was *T. atlas*, of the Pliocene of the Sivalik hills with a skull nearly 8 in. long, but the shell probably measured not more than 6 ft. in length, the restored specimen in the Natural History Museum at South Kensington being exaggerated. *T. perpigniana* of Pliocene France was also large. Large land tortoises, with a length of shell of more than 2 ft., became restricted to two widely separated regions of the world, viz. the Galapagos Islands (called thus after the Spanish *galapago*, *i.e.* tortoise), and islands in the western Indian Ocean viz. the Mascarenes (Bourbon, Mauritius and Rodriguez) and Aldabra. When they became extinct in Madagascar is not known, but *T. grandidieri* was a very large kind, of apparently very recent date. At the time of their discovery those smaller islands were uninhabited by man or any predaceous mammal. It was on these peaceful islands that land tortoises lived in great numbers; with plenty of food there was nothing for them to do but to feed, to propagate, to grow and to vary. Most of the islands were or are inhabited by one or more typical, local forms. As they provided, like the equally ill-fated dodo and solitaire, a welcome provision of excellent meat, ships carried them about, to be slaughtered as occasion required, and soon almost exterminated them; some were occasionally liberated on other islands, for instance, on the Seychelles and on the Chagos, or they were left as presents, in Ceylon, Java or on Rotuma near the Fijis. Thus it has come to pass that the few survivors have been very much scattered. The small genuine stock at Aldabra is now under government protection, in a way. A large male of *T. gigantea* or *elephantina* or *hololissa* or *ponderosa*, was brought to London and weighed 870 lb; another specimen had in 1908 been living at St Helena for more than one hundred years. A specimen of *T. daudini*, native of the South Island of Aldabra, was known for many years on Egmont Island, one of the Chagos group, then it was taken to Mauritius and then to England, where of course it soon died; its shell measures 55 in. in a straight line, and it weighed 560 lb. The type specimen of *T. sumeirei*, supposed to have come originally from the Seychelles, was in 1908 still kept in the barrack grounds at Port Louis, Mauritius, and had been known as a large tortoise for about 150 years. *T. vosmaeri* was a very thin-shelled species in Rodriguez. Of the Galapagos species *T. ephippium* still survives on Duncan Island; *T. abingdoni* lived on Abingdon Island; of *T. elephantopus* or *vicina*, G. Baur still collected 21 specimens in 1893 on Albemarle Island. One monster of this kind is said to have measured 56 in. over the curve of the carapace, with a skull a little more than 7 in. in length. All the Galapagos species are remarkable for their comparatively small head and the very long neck, which is much larger and more slender than that of the eastern species.

Family 6. Chelonidae. Marine turtles, with only two recent genera, with three widely distributed species. The limbs are paddle-shaped, with only one or two claws, and the shell is covered with horny shields. The neck is short and incompletely retractile. The parietals, post-frontals, squamosals, quadrato-jugals, and jugals are much expanded and form an additional or false roof over the temporal region of the skull.

The Chelonidae are a highly specialized offshoot of the Cryptodira, adapted to marine life. Fundamentally they agree most with the Testudinidae, and there is nothing primitive about them except that they still possess complete series of inframarginal shields.

Chelone, with only 4 pairs of costal shields, with 5 neurals and a broad nuchal. *C. mydas* s. *viridis*, the "green or edible turtle,"

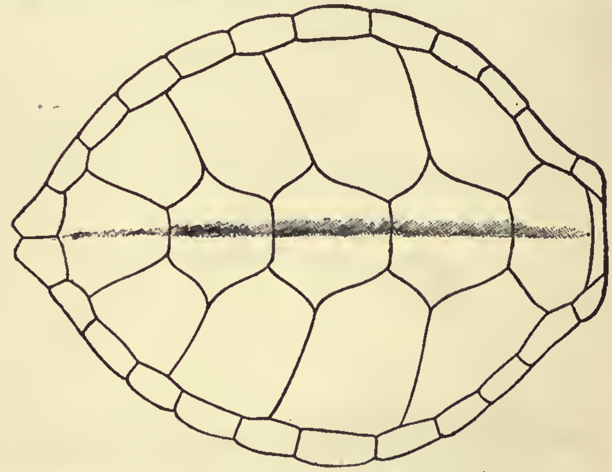

FIG. 5.—Green Turtle (*Chelone mydas*).

has, when adult, a nearly smooth shell. It attains a length of nearly 4 ft., and may then weigh more than three hundredweight. Their food consists of algae, and of *Zostera marina*. Their capture forms a regular pursuit wherever they occur in any numbers. Comparatively few are caught in the open sea, others in staked nets, but the majority are intercepted at well-known periods and localities where they go ashore to deposit their eggs. These are round, with a parchment-like shell and buried in the sand, above the high-tide mark, as many as 100 to 250 being laid by one female. They are eagerly searched for and eaten. The famous turtle-soup is made not only of the meat and the fat, but also from the thick and gelatinous layer of subcutaneous tissue which lines the inside of the shell. Only the females are eaten; the males, recognizable by the longer tail, are rejected at the London market. This species inhabits the Atlantic, Indian and Pacific Oceans.

C. imbricata, the "hawksbill turtle." The shields are thick, strongly overlapping each other from before backwards, but in old specimens the shields lose their keel, flatten and become juxtaposed. The horny cover of the upper jaw forms a hooked beak. This species lives upon fish and molluscs and is not eaten; but is much persecuted for the horny shields which yield the

" tortoise-shell, " so far as this is not a fraudulent imitation. When heated in oil, or boiled, the shields (which singly are not thick enough to be manufactured into larger articles) can be welded together under pressure and be given any desired shape. The " hawksbill "

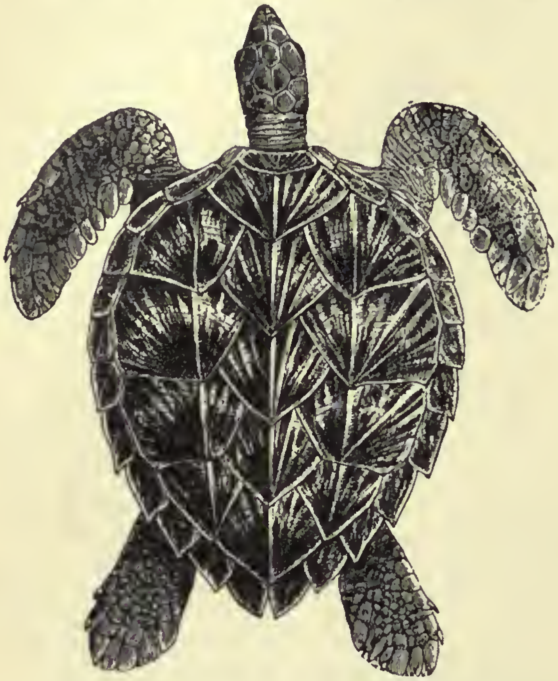

FIG. 6.—Hawksbill Turtle (*Chelone imbricata*).

ranges over all the tropical and sub-tropical seas and scarcely reaches 3 ft. in length, but such a shell yields up to 8 lb of tortoiseshell.

Thalassochelys caretta, the " loggerhead, " has normally five pairs of costal shields, but whilst the number of shields in the genus *Chelone* is very constant, that of the loggerhead varies individually to an astonishing extent. The greatest number of neurals observed, and counting the nuchal as the first, is 8, and 8 pairs of costal, in all 24; the lowest numbers are 6 neurals with 5 pairs of costals; odd costals are frequent. The most interesting facts are that some of the supernumerary shields are much smaller than the others, sometimes mere vestiges in all stages of gradual suppression, and that the abnormalities are much more common in babies and small specimens than in adults. The importance of these orthogenetic variations has been discussed by H. Gadow in A. Willey's *Zoolog. Results*, pt. iii. p. 207–222, pls. 24, 25 (Cambridge 1899).

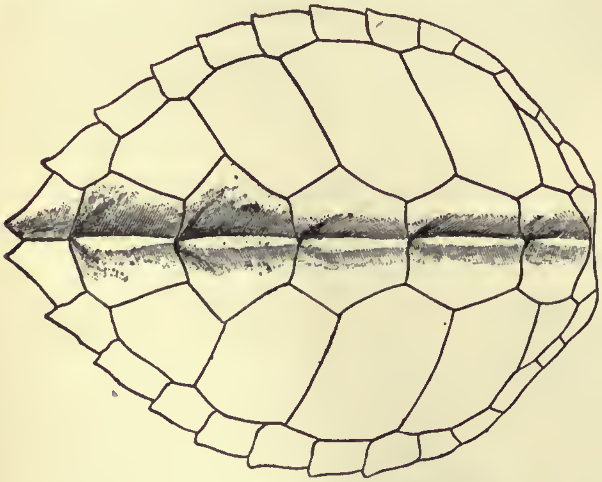

FIG. 7.—Loggerhead (*Thalassochelys caretta*).

The " loggerhead " is carnivorous, feeding on fish, molluscs and crustaceans, and is not esteemed as food. A great part of the turtle-oil which finds its way into the market is obtained from it; its tortoiseshell is of an inferior quality. Besides all the intertropical seas it inhabits the Mediterranean, and is an accidental visitor of the western coasts of Europe. The old specimen captured on the Dutch coast in 1894 contained the enormous number of 1150 eggs.

Super-family 2. Pleurodira.—The long neck bends laterally and is tucked away between the anterior portion of the carapace and the plastron. The dorsal and ventral ends of the pelvis are anchylosed to the shell. Fresh-water tortoises of South America, Australia, Africa and Madagascar.

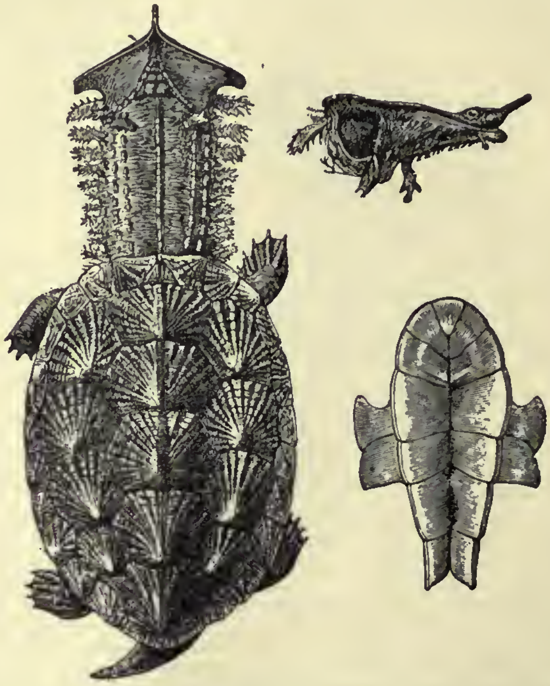

FIG. 8.—The Matamata (*Chelys fimbriata*) with side view of head, and separate view of plastron.

Family I. Pelomedusidae.—Neck completely retractile. Carapace covered with horny shields, of which the nuchal is wanting. Plastron composed of 11 plates. With 24 marginal and 13 plastral shields,

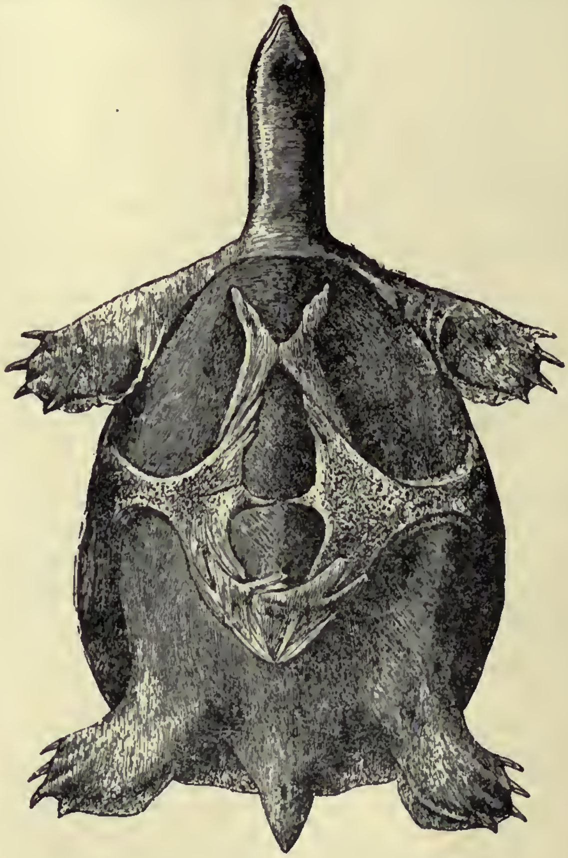

FIG. 9.—Lower view of *Trionyx euphratica*.

inclusive of a conspicuous intergular. *Sternothaerus* in Africa and Madagascar. *Pelomedusa galeata* in Madagascar and from the Cape to the Sinaitic peninsula. *Podocnemis* is common in tropical South America, *e.g. P. expansa* of Brazilian rivers, noteworthy for the millions of eggs which are, or were, annually collected for the sake of their oil. Bates (*The Naturalist on the River Amazon*) gives a most interesting account of these turtles, which are entirely frugivorous.

Family 2. Chelydidae.—The neck, when bent, remains partly exposed. Shell covered with shields. Plastron composed of 9 plates, but covered with 13 shields. This family, still represented by nearly 30 species, with 8 genera, is found in South America and in Australia. *Chelys fimbriata*, the "matamata" in the rivers of Guiana and North Brazil; total length about 3 ft.; with animal diet. *Hydromedusa, e.g. tectifera*, with very long neck, in Brazil, much resembling *Chelodina, e.g. longicollis* of the Australian region.

Family 3. Carettochelydidae.—*Carettochelys insculpta*, the only species, in the Fly river of New Guinea; still imperfectly known. This peculiar turtle seems to stand in the same relation to the Chelydidae and to the Trionychidae as do the Chelonidae to the Testudinidae by the transformation of the limbs into paddles with only two claws, and the complete reduction of the horny shields upon the shell, which is covered with soft skin. The plastron is composed of 9 plates; the 6 neural plates are all separated from one another by the costals. The premaxilla is single, as elsewhere only in

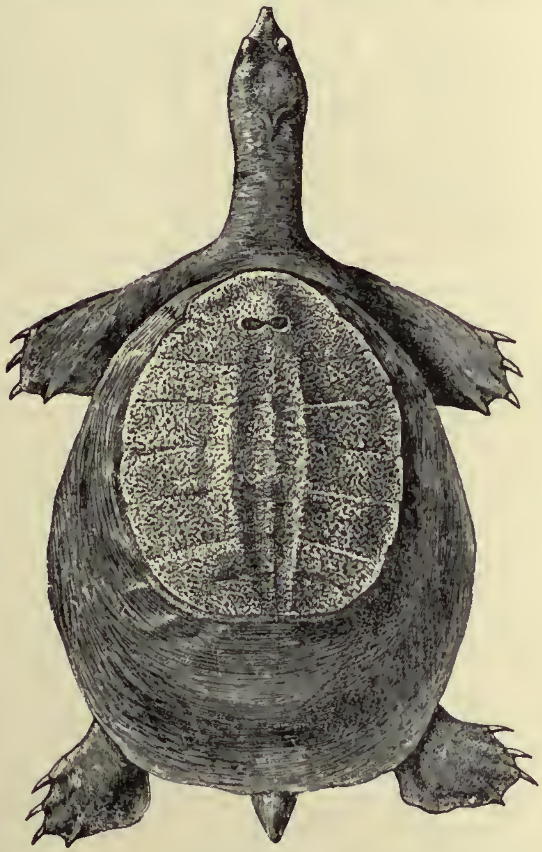

FIG. 10.—Upper view of the Turtle of the Euphrates (*Trionyx euphratica*).

Chelys and in the Trionychidae. The neck is short and non-retractile. Length of shell about 18 in.

Super-family 3. Trionychoidea.—The shell is very flat and much smaller than the body, and covered with soft leathery skin, but traces of horny structures are still represented, especially in the young of some species, by numerous scattered little spikes on the back of the shell and even on the soft parts of the back. The limbs are short, broadly webbed and only the three inner digits are provided with claws. Head and neck are retractile, bending in a sigmoid curve in a vertical plane. The jaws are concealed by soft lip-like flaps and the nose forms a short soft proboscis. The temporal region is not covered in by any arches; the quadrate is trumpet-shaped as in the Chelydidae, but the jugular arch is complete. The pelvis is not anchylosed to the shell. The carapace is much reduced in size, the ribs extending beyond the costal plates, and there are no marginals; except in the African *Cyclanorbis* the neural plates form a continuous series. All the nine elements of the plastron are deficient and but very loosely connected with each other. Most of these reductions in the skeletal and tegumentary armature are the result of life in muddy waters, in the bottom of which these creatures bury themselves with only the head exposed. They feed upon aquatic animals; those which are partial to hard-shelled molluscs soon wear down the sharp horny edges of the jaws, and thick horny crushing pads are developed in their stead. They only crawl upon land in order to lay their round brittle eggs. Trionyxes inhabit the rivers of Asia, Africa and North America. *Trionyx ferox*, the "soft-shelled turtle," in the whole of the Mississippi basin and in the chain of the great northern lakes. *T. triunguis* in Africa, the largest species, with a length of shell of 3 ft. *T. hurum* and *T. gangeticus* are the commonest Indian species. The young are ornamented with two or three pairs of large, round, ocellated spots on the back. (H. F. G.)

TORTOISESHELL. The tortoiseshell of commerce consists of the epidermic plates covering the bony carapace of the hawksbill turtle, *Chelonia imbricata*, the smallest of the sea turtles. The plates of the back or carapace, technically called the head, are 13 in number, 5 occupying the centre, flanked by 4 on each side. These overlap each other to the extent of one-third of their whole size, and hence they attain a large size, reaching in the largest to 8 in. by 13 in., and weighing as much as 9 oz. The carapace has also 24 marginal pieces, called hoofs or claws, forming a serrated edge round it; but these, with the plates of the plastron, or belly, are of inferior value. The plates of tortoiseshell consist of horny matter, but they are harder, more brittle, and less fibrous than ordinary horn. Their value depends on the rich mottled colours they display—a warm translucent yellow, dashed and spotted with rich brown tints—and on the high polish they take and retain. The finest tortoiseshell is obtained from the Eastern Archipelago, particularly from the east coast of Celebes to New Guinea; but the creature is found and tortoiseshell obtained from all tropical coasts, large supplies coming from the West Indian Islands and Brazil.

Tortoiseshell is worked precisely as horn; but, owing to the high value of the material, care is taken to prevent any waste in its working. The plates, as separated by heat from the bony skeleton, are keeled, curved, and irregular in form. They are first flattened by heat and pressure, and superficial inequalities are rasped away. Being harder and more brittle than horn, tortoiseshell requires careful treatment in moulding it into any form, and as high heat tends to darken and obscure the material it is treated at as low a heat as practicable. For many purposes it is necessary to increase the thickness or to add to the superficial size of tortoiseshell, and this is readily done by careful cleaning and rasping of the surfaces to be united, softening the plates in boiling water or sometimes by dry heat, and then pressing them tightly together by means of heated pincers or a vice. The heat softens and liquefies a superficial film of the horny material, and that with the pressure effects a perfect union of the surfaces brought together. Heat and pressure are also employed to mould the substance into boxes and the numerous artificial forms into which it is made up.

Tortoiseshell has been a prized ornamental material from very early times. It was one of the highly esteemed treasures of the Far East brought to ancient Rome by way of Egypt, and it was eagerly sought by wealthy Romans as a veneer for their rich furniture. In modern times it is most characteristically used in the elaborate inlaying of cabinet-work known as buhl furniture, and in combination with silver for toilet articles. It is also employed as a veneer for small boxes and frames. It is cut into combs, moulded into snuff-boxes and other small boxes, formed into knife-handles, and worked up into many other similar minor articles. The plates from certain other tortoises, known commercially as turtle-shell, possess a certain industrial value, but they are either opaque or soft and leathery, and cannot be mistaken for tortoiseshell. A close imitation of tortoiseshell can be made by staining translucent horn or by varieties of celluloid.

TORTOLÌ, a town and episcopal see of Sardinia, on the east coast, 140 m. N.N.E. of Cagliari by rail (55 m. direct). Pop. (1901), 2105. It lies 60 ft. above sea-level to the south-west of a large lagoon, which renders it unhealthy. The harbour is $2\frac{1}{2}$ m. to the east, and serves for the export of the wine and agricultural produce of the Ogliastra. A little to the south of Tortolì was the station of Sulci on the Roman coast road, known to us only from the itineraries.

TORTONA (anc. *Dertona*), a town and episcopal see of Piedmont, Italy, in the province of Alessandria, from which it is 14 m. E. by rail, on the right bank of the Scrivia, at the northern foot of the Apennines, 394 ft. above sea-level. Pop. (1901), 11,308 (town); 17,419 (commune). Tortona is on the main line from Milan to Genoa; from it a main line runs to Alessandria, a branch to Castelnuovo Scrivia, and a steam tramway to Sale. Its fortifications were destroyed by the French after Marengo (1799); the ramparts are now turned into shady promenades. The cathedral, erected by Philip II., contains a remarkably fine Roman sarcophagus of the Christian period. Silk-weaving, tanning and hat-making are the chief industries; and there is some trade in wine and grain.

Dertona, which may have become a Roman colony as early as the 2nd century B.C. and certainly did so under Augustus, is spoken of by Strabo as one of the most important towns of Liguria. It stood at the point of divergence of the Via Postumia (see LIGURIA) and the Via Aemilia, while a branch road ran hence to Pollentia. A number of ancient inscriptions and other objects have been found here. In the middle ages Tortona was zealously attached to the Guelphs, on which account it was twice laid waste by Frederick Barbarossa, in 1155 and 1163. (T. As.)

TORTOSA, a fortified city of north-east Spain, in the province of Tarragona; 40 m. by rail W.S.W. of the city of Tarragona, on the river Ebro 22 m. above its mouth. Pop. (1900), 24,452. Tortosa is for the most part an old walled town on the left bank of the river, with narrow, crooked and ill-paved streets, in which the houses are lofty and massively built of granite. But some parts of the old town have been rebuilt, and there is a modern suburb on the opposite side of the Ebro. The slope on which old Tortosa stands is crowned with an ancient castle, which has been restored and converted into barracks and a hospital. All the fortifications are obsolete. The cathedral occupies the site of a Moorish mosque built in 914. The present structure, which dates from 1347, has its Gothic character disguised by a classical façade with Ionic pillars and much tasteless modernization. The stalls in the choir, carved by Cristobal de Salamanca in 1588–1593, and the sculpture of the pulpits, as well as the iron-work of the choir-railing and some of the precious marbles with which the chapels are adorned, deserve notice. The other public buildings include an episcopal palace, a town-hall and numerous churches. There are manufactures of paper, hats, leather, ropes, porcelain, majolica, soap, spirits, and ornaments made of palm leaves and grasses. There is an important fishery in the river, and the harbour is accessible to vessels of 100 tons burden. Corn, wine, oil, wool, silk, fruits and liquorice (a speciality of the district) are exported. The city is connected with Barcelona and Valencia by the coast railway, and with Saragossa by the Ebro valley line; it is also the terminus of a railway to San Carlos de la Rápita on the Mediterranean. Near Tortosa are rich quarries of marble and alabaster.

Tortosa, the *Dertosa* of Strabo and the *Colonia Julia Augusta Dertosa* of numerous coins, was a city of the Ilercaones in Hispania Tarraconensis. Under the Moors it was of great importance as the key of the Ebro valley. It was taken by Louis the Pious in 811 (after an unsuccessful siege two years before), but was soon recaptured. Having become a haunt of pirates, and exceedingly injurious to Italian commerce, it was made the object of a crusade proclaimed by Pope Eugenius III. in 1148, and was captured by Ramon Berenguer IV., count of Barcelona, assisted by Templars, Pisans and Genoese. An attempt to recapture the city in 1149 was defeated by the heroism of the women, who were thenceforth empowered by the count to wear the red sash of the Order of La Hacha (The Axe), to import their clothes free of duty, and to precede their bridegrooms at weddings. Tortosa fell into the hands of the duke of Orleans in 1708; during the Peninsular War it surrendered in 1811 to the French under Suchet, who held it till 1814.

TORTURE (from Lat. *torquere*, to twist), the general name for innumerable modes of inflicting pain which have been from time to time devised by the perverted ingenuity of man, and especially for those employed in a legal aspect by the civilized nations of antiquity and of modern Europe. From this point of view torture was always inflicted for one of two purposes: (1) As a means of eliciting evidence from a witness or from an accused person either before or after condemnation; (2) as a part of the punishment. The second was the earlier use, its function as a means of evidence arising when rules were gradually formulated by the experience of legal experts.

Torture as a part of the punishment may be regarded as including every kind of bodily or mental pain beyond what is necessary for the safe custody of the offender (with or without enforced labour) or the destruction of his life—in the language of Bentham, an "afflictive" as opposed to a "simple" punishment. Thus the unnecessary sufferings endured in English prisons before the reforms of John Howard, the *peine forte et dure*, and the drawing and quartering in executions for treason, fall without any straining of terms under the category of torture.

The whole subject is now one of only historical interest as far as Europe is concerned. It was, however, up to a comparatively recent date an integral part of the law of most countries (to which England, Aragon and Sweden[1] formed honourable exceptions)—as much a commonplace of law as trial by jury in England.[2] The prevailing view, no doubt, was that truth was best obtained by confession, the *regina probationum*. Where confession was not voluntary, it must be extorted. Speaking generally, torture may be said to have succeeded the ordeal and trial by battle. Where these are found in full vigour, as in the capitularies of Charlemagne, there is no provision for torture. It was no doubt accepted reluctantly as being a *quasi judicium Dei*, but tolerated in the absence of any better means of eliciting truth, especially in cases of great gravity, on the illogical assumption that extraordinary offences must be met by extraordinary remedies. Popular feeling too, says Verri, preferred, as causes of evil, human beings who could be forced to confess, rather than natural causes which must be accepted with resignation. Confession, as *probatio probatissima* and *vox vera*, was the best of all evidence, and all the machinery of law was moved to obtain it. The trials for witchcraft remain on record as a refutation of the theory.

The opinions of the best lay authorities have been almost unanimously against the use of torture, even in a system where it was as completely established as it was in Roman law. "Tormenta," says Cicero,[3] in words which it is almost impossible to translate satisfactorily, "gubernat dolor, regit quaesitor, flectit libido, corrumpit spes, infirmat metus, ut in tot rerum angustiis nihil veritati loci relinquatur." Seneca says bitterly, "it forces even the innocent to lie." St Augustine[4] recognizes the fallacy of torture. "If," says he, "the accused be innocent, he will undergo for an uncertain crime a certain punishment, and that not for having committed a crime, but because it is unknown whether he committed it." At the same time he regards it as excused by its necessity. The words of Ulpian, in the *Digest* of Justinian,[5] are no less impressive: "The torture (*quaestio*) is not to be regarded as wholly deserving or wholly undeserving of confidence; indeed, it is untrustworthy, perilous and deceptive. For most men, by patience or the severity of the torture, come so to despise the torture that the truth cannot be elicited from them; others are so impatient that they will lie in any direction rather than suffer the torture; so it happens that they depose to contradictions and accuse not only themselves but others." Montaigne's[6] view of torture as a part of the punishment is a most just one: "All that exceeds a simple death appears to me absolute cruelty; neither can our justice expect that he whom the fear of being executed by being beheaded or hanged will not restrain should be any more awed by the imagination of a languishing fire, burning pincers, or the wheel." He continues with the curious phrase: "He whom the judge has tortured (*gehenné*) that he may not die innocent, dies innocent and tortured." Montesquieu[7] speaks of torture in a most guarded manner, condemning it, but without giving reasons, and eulogizing England for doing without it. The system was condemned by Bayle and Voltaire with less reserve. Among

[1] But even in these countries, whatever the law was, torture certainly existed in fact.

[2] Primitive systems varied. There is no trace of it in Babylonian or Mosaic law, but Egyptian and Assyrian provided for it; and the story of Regulus seems to show that it was in use at Carthage.

the Germans, Sonnenfels (1766), and, among the Italians, Beccaria,[1] Verri[2] and Manzoni[3] will be found to contain most that can be said on the subject. The influence of Beccaria in rendering the use of torture obsolete was undoubtedly greater than that of any other legal reformer. The great point that he makes is the unfair incidence of torture, as minds and bodies differ in strength. Moreover, it is, says he, to confound all relations to expect that a man should be both accuser and accused, and that pain should be the test of truth, as though truth resided in the muscles and fibres of a wretch under torture. The result of the torture is simply a matter of calculation. Given the force of the muscles and the sensibility of the nerves of an innocent person, it is required to find the degree of pain necessary to make him confess himself guilty of a given crime. Bentham's[4] objection to torture is that the effect is exactly the reverse of the intention. "Upon the face of it, and probably enough in the intention of the framers, the object of this institution was the protection of innocence; the protection of guilt and the aggravation of the pressure upon innocence was the real fruit of it." The apologists of torture are chiefly among jurists. But theoretical objections to it are often urged by the authors of books of practice, as by Damhouder, von Rosbach, von Boden, Voet, and others named below under the head of *The Netherlands*. It is worthy of note as illustrative of the feeling of the time that even Bacon[5] compares experiment in nature to torture in civil matters as the best means of eliciting truth. Muyart de Vouglans[6] derives the origin of torture from the law of God. Other apologists are Simancas, bishop of Badajoz,[7] Engel,[8] Pedro de Castro,[9] and in England Sir R. Wiseman.[10]

Greece.—The opinion of Aristotle was in favour of torture as a mode of proof. "It is," he says, "a kind of evidence, and appears to carry with it absolute credibility because a kind of constraint is applied." It is classed as one of the "artless persuasions" (ἄτεχνοι πίστεις).[11] "It was the surest means of obtaining evidence, says Demosthenes.[12] At Athens slaves, and probably at times resident aliens, were tortured,[13] in the former case generally with the master's consent, but torture was seldom applied to free citizens,[14] such application being forbidden by a psephism passed in the archonship of Scamandrius. After the mutilation of the Hermae in 415 B.C. a proposition was made, but not carried, that it should be applied to two senators named by an informer. In this particular case Andocides gave up all his slaves to be tortured.[15] Torture was sometimes inflicted in open court. The rack was used as a punishment even for free citizens. Antiphon was put to death by this means.[16] The torture of Nicias by the Syracusans is alluded to by Thucydides[17] as an event likely to happen, and it was only in order to avoid the possibility of inconvenient disclosures that he was put to death without torture. Isocrates and Lysias refer to torture under the generic name of στρέβλωσις, but it was generally called βάσανοι, in the plural, like *tormenta*. As might be expected, torture was frequently inflicted by the Greek despots, and both Zeno and Anaxarchus are said to have been put to it by such irresponsible authorities. At Sparta the despot Nabis was accustomed, as we learn from Polybius,[18] to put persons to death by an instrument of torture in the form of his wife Apega, a mode of torture no doubt resembling the *Jungfernkuss* once used in Germany. At Argos, as Diodorus informs us (xv. 57), certain conspirators were put to the torture in 371 B.C.[19]

[19] For the whole subject, see *Dict. Ant.*, *s.v. Tormenta.*

Rome.—The Roman system was the basis of all subsequent European systems which recognized torture as a part of their procedure, and the rules attained a refinement beyond anything approached at Athens. The law of torture was said by Cicero to rest originally on custom (*mores majorum*), but there is no allusion to it in the Twelve Tables. There are frequent allusions to it in the classical writers,[20] both of the republic and the empire. The law, as it existed under the later empire, is contained mainly in the titles *De quaestionibus*[21] of the *Digest* and the *Code*[22]—the former consisting largely of opinions from the *Sententiae receptae* of Paulus,[23] the latter being for the most part merely a repetition of constitutions contained in the Theodosian Code.[24] Both substantive law and procedure were dealt with by these texts of Roman law, the latter, however, not as fully as in medieval codes, a large discretion being left to the judges. Torture was used both in civil and criminal trials, but in the former only upon slaves and freedmen or infamous persons (after *Nov.* xc. 1, 1, upon *ignoti* and *obscuri* if they showed signs of corruption)—such as gladiators—and in the absence of *alia manifesta indicia*,[25] as in cases affecting the inheritance (*res hereditariae*). Its place in the case of free citizens was taken by the reference to the oath of the party. During the republic torture appears to have been confined to slaves in all cases, but with the empire a free man became liable to it if accused of a crime, though in most cases not as a witness. On an accusation of treason every one, whatever his rank, was liable to torture, for in treason the condition of all was equal.[26] The same was the case of those accused of sorcery (*magi*), who were regarded as *humani generis inimici*.[27] A wife might be tortured (but only after her slaves had been put to the torture) if accused of poisoning her husband. In accusations of crimes other than treason or sorcery, certain persons were protected by the dignity of their position or their tender age. The main exemptions were contained in a constitution of Diocletian and Maximian, and included soldiers, nobles of a particular rank, *i.e. eminentissimi* and *perfectissimi*, and their descendants to the third generation, and *decuriones* and their children to a limited extent (*tormenta moderata*)—that is to say, they were subject to the torture of the *plumbatae* in certain cases, such as fraud on the revenue and extortion. In addition to these, priests (but not clergy of a lower rank), children under fourteen and pregnant women were exempt. A free man could be tortured only where he had been inconsistent in his depositions, or where there was a suspicion that he was lying.[28] The rules as to the torture of slaves were numerous and precise. It was a maxim of Roman law that torture of slaves was the most efficacious means of obtaining truth.[29] They could be tortured either as accused or as witnesses for their masters in all cases, but against their masters only in accusations of treason, adultery, frauds on the revenue, coining, and similar offences (which were regarded as a species of treason), attempts by a husband or wife on the life of the other, and in cases where a master had bought a slave for the special reason that he should not give evidence against him. The privilege from accusations by the slave extended to the master's father, mother, wife, or tutor, and also to a former master. On the same principle a freedman could not be tortured against his patron. The privilege did not apply where the slave was joint property, and one of his masters had been murdered by the other, or where he was the property of a corporation, for in such a case he could be tortured in a charge against a member of the corporation. Slaves belonging to the inheritance could be tortured in actions concerning the inheritance. The adult slaves of a deceased person could be tortured where the deceased had been murdered. In a charge of adultery against a wife, her husband's, her own and her father's slaves could be put to the torture. A slave manumitted for the express purpose of escaping torture was regarded as still liable to it. Before putting a slave to torture without the consent of his master, security must be given to the master for his value and the oath of calumny must be taken.[30] The master of a slave tortured on a false accusation could recover double his value from the accuser. The undergoing of torture had at one time a serious effect upon the after-life of the slave, for in the time of Gaius a slave who had been tortured could on manumission obtain no higher civil rights than those of a *dediticius*.[31] The rules of procedure were conceived in a spirit of as much fairness as such rules could be. Some of the most important were these: The amount of torture was at the discretion of the judge, but it was to be so

[20] An instance is Pliny's letter to Trajan (*Epist.* x. 97), where he mentions having put to the torture two Christian deaconesses (*ministrae*). The words are *confitentes iterum ac tertio interrogavi.* This supports Tertullian's objection to the torture of Christians, *torquemur confitentes* (*Apol.* c. 2).
[21] *Quaestio* included the whole process of which torture was a part. In the words of Cujacius, *Quaestio est interrogatio quae fit per tormenta, vel de reis, vel de testibus qui facto intervenisse dicuntur.*
[22] *Dig.* xlviii. 18; *Cod.* ix. 41.

[31] Gaius i. 13.

applied as not to injure life or limb. If so applied the judge was *infamis*. The examination was not to begin by torture; other proofs must be exhausted first. The evidence[1] must have advanced so far that nothing but the confession of the slave was wanting to complete it. Those of weakest frame and tenderest age were to be tortured first. Except in treason, the unsupported testimony of a single witness was not a sufficient ground for torture. The voice and manner of the accused were to be carefully observed. A spontaneous confession, or the evidence of a personal enemy, was to be received with caution. Repetition of the torture could only be ordered in case of inconsistent depositions or denial in the face of strong evidence. There was no rule limiting the number of repetitions. Leading questions were not to be asked. A judge was not liable to an action for anything done during the course of the examination. An appeal from an order to torture was competent to the accused, except in the case of slaves, when an appeal could be made only by the master.[2] The appellant was not to be tortured pending the appeal, but was to remain in prison.[3] The *quaesitor* asked the questions, the *tortores* applied the instruments. The principal forms of torture in use were the *equuleus*, or rack (mentioned as far back as Cicero),[4] the *plumbatae*, or leaden balls, the *ungulae*, or barbed hooks, the *lamina*, or hot plate, the *mala mansio*,[5] and the *fidiculae*, or cord compressing the arm. Other allusions in the *Digest* and *Code*, in addition to those already cited, may be shortly noticed. The testimony of a gladiator or infamous person (such as an accomplice) was not valid without torture.[6] This was no doubt the origin of the medieval maxims (which were, however, by no means universally recognized)—*Vilitas personae est justa causa torquendi testem*, and *Tortura purgatur infamia*. Torture could not be inflicted during the forty days of Lent.[7] Robbers and pirates might be tortured even on Easter day, the divine pardon being hoped for where the safety of society was thus assured.[8] Capital punishment was not to be suffered until after conviction or confession under torture.[9] Withdrawal from prosecution (*abolitio*) was not to be allowed as a rule after the accused had undergone the torture.[10] In charges of treason the accuser was liable to torture if he did not prove his case.[11] The infliction of torture, not judicial, but at the same time countenanced by law, was at one time allowed to creditors. They were allowed to keep their debtors in private prisons, and most cruelly ill-use them, in order to extort payment.[12] Under the empire private prisons were forbidden.[13] In the time of Juvenal the Roman ladies actually hired the public torturers to torture their domestic slaves.[14] As a part of the punishment torture was in frequent use. Crucifixion, mutilation, exposure to wild beasts in the arena and other cruel modes of destroying life were common, especially in the time of the persecution of the Christians under Nero.[15] Crucifixion as a punishment was abolished by Constantine in 315, in veneration of the memory of Him who was crucified for mankind. On the other hand, where the interests of the Church were concerned the tendency was in favour of greater severity. Thus, by the Theodosian Code, a heretic was to be flogged with lead (*contusus plumbo*) before banishment,[16] and Justinian made liable to torture and exile any one insulting a bishop or priest in a church, or saying litany, if a layman.[17]

The *Leges barbarorum* are interesting as forming the link of connexion between the Roman and the medieval systems. Through them the Roman doctrines were transmitted into the Roman law countries. The barbarian codes were based chiefly on the Theodosian Code. As compared with Roman law there seems to be a leaning towards humanity, *e.g.* the provision for redemption of a slave after confession by s. 40 of the *Lex salica*. After the edict of Gundobald in 501 the combat rather than the torture became the expression of the *judicium Dei*.

The Church.—As far as it could the Church adopted the Roman law. The Church generally secured the almost entire immunity of its clergy, at any rate of the higher ranks, from torture by civil tribunals;[18] but in general, where laymen were concerned all persons were equal. In many instances councils of the Church pronounced against torture, *e.g.* in a synod at Rome in 384.[19] Torture even of heretics seems to have been originally left to the ordinary tribunals. Thus a bull of Innocent IV., in 1282, directed the torture of heretics by the civil power, as being robbers and murderers of souls, and thieves of the sacraments of God.[20] The Church also enjoined torture for usury.[21] A characteristic division of torture, accepted by the Church, but not generally acknowledged by lay authorities, was into spiritual and corporal, the latter being simply the imposition of the oath of purgation, the only form originally in use in the ecclesiastical courts. The canon law contains little on the subject of torture, and that little of a comparatively humane nature. It laid down that it was no sin in the faithful to inflict torture,[22] but a priest might not do so with his own hands,[23] and charity was to be used in all punishments.[24] No confession was to be extracted by torture[25] and it was not to be ordered *indiciis non praecedentibus*.[26] The principal ecclesiastical tribunal by which torture was inflicted in more recent times was the Inquisition. The code of instructions issued by Torquemada in Spain in 1484 provided that an accused person might be put to the torture if *semiplena probatio* existed against the accused—that is, so much evidence as to raise a grave and not merely a light presumption of guilt, often used for the evidence of one eye or ear witness of a fact. If the accused confessed during torture, and afterwards confirmed the confession, he was punished as convicted; if he retracted, he was tortured again, or subjected to extraordinary punishment. One or two inquisitors, or a commissioner of the Holy Office, were bound to be present at every examination. Owing to the occurrence of certain cases of abuse of torture, a decree of Philip II. was issued, in 1558, forbidding the administration of torture without an order from the council. But this decree does not appear to have been fully observed. By the edict of the inquisitor-general Valdés, in 1561, torture was to be left to the prudence and equity of the judges. They must consider motives and circumstances before decreeing torture, and must declare whether it is to be employed *in caput proprium*, *i.e.* to extort a confession, or *in caput alienum*, *i.e.* to incriminate an accomplice. Torture was not to be decreed until the termination of the process and after defence heard, and the decree was subject to appeal, but only in doubtful cases, to the Council of the Supreme. It was also only in doubtful cases that the inquisitors were bound to consult the council; where the law was clear (and of this they were the judges) there need be no consultation, and no appeal was allowed. On ratification twenty-four hours afterwards of a confession made under torture, the accused might be reconciled, if the inquisitors believed him to be sincerely repentant. If convicted of bad faith he might be relaxed, *i.e.* delivered to the secular power to be burned. The inquisitors had a discretion to allow the accused to make the canonical purgation by oath instead of undergoing corporal torture, but the rule which allows this to be done at the same time discountenances it as fallacious. It is remarkable that the rules do not allow much greater efficacy to torture. They speak of it almost in the terms of Roman law as dangerous and uncertain, and depending for its effects on physical strength.[27] Torture had ceased to be inflicted before the suppression of the Inquisition, and in 1816 a papal bull decreed that torture should cease, that proceedings should be public, and that the accuser should be confronted with the accused. The rules in themselves were not so cruel as the construction put upon them by the inquisitors. For instance, by Torquemada's instructions torture could not be repeated unless in case of retractation. This led to the subtlety of calling a renewed torture a continuation,

---

[1] The evidence on which the accused might be tortured was expressed in Roman law by the terms *argumentum* and *indicium* (used technically as early as Cicero, *Verres*, i. 10 and 17). The latter term, as will be seen, afterwards became one of the most important in the law of torture, but the analysis of *indicium* is later than Roman law. *Indicium* was not quite the same thing as *semiplena probatio*, though the terms appear to be occasionally used as synonyms. *Indicium* was rather the foundation or cause of *probatio*, whether *plena* or *semiplena*. An *indicium* or a concurrence of *indicia* might, according to circumstances, constitute a *plena* or *semiplena probatio*. The phrase *legitima indicia* was sometimes used. In Sir T. Smith's work, c. 24 (see below), *index* means a prisoner acting as an approver under torture. *Tormentum*, *tortura* and *quaestio* appear to be equivalent terms. The medieval jurists derived the first of these from *torquere mentem*, an etymology as false as *testamentum* from *testatio mentis* (*Inst.* ii. 10 pr.).

and not a repetition. The rules of Torquemada and of Valdés are those of the greatest historical importance, the latter forming the code of the Holy Office until its suppression, not only in Spain, but in other countries where the Inquisition was established. But several other manuals of procedure existed before the final perfection of the system by Valdés. The earliest is perhaps the instructions for inquisitors (*Directorium inquisitorum*) compiled a century earlier than Torquemada by Nicholas Eymerico, grand inquisitor of Aragon about 1368.[1] Rules of practice were also framed two centuries later by Simancas, whose position as an apologist has been already stated. The textbook of procedure of the Italian Inquisition was the *Sacro arsenale*.[2] In 1545 and 1550 instructions for the guidance of inquisitors were issued by Charles V. The liability of a judge for exceeding the law was not always recognized by the Inquisition to the same extent as by the lay tribunals. Llorente gives an instance of a warrant by an inquisitor to a licentiate ordering the torture of an accused person, and protesting that, in case of death or fracture of limbs, the fact is not to be imputed to the licentiate.[3]

Thus far of the law. In practice all the ingenuity of cruelty was exercised to find new modes of torment.[4] These cruelties led at times to remonstrance from the civil power. One example is the edict of Philip II. just mentioned. Another and an earlier one is an *ordonnance* of Philip the Fair, in 1302, bidding the Inquisition confine itself within the limits of the law.[5] At Venice the senate decreed that three senators should be present as inquisitors.

As the practice of torture became more systematized, it grew to be the subject of casuistical inquiry by churchmen to an extent far exceeding the scanty discussion of the question in the text of the canon law. It will be sufficient here to cite as an example the treatment of it by Liguori, who incorporates the opinions of many of the Spanish casuists. On the whole, his views appear to be more humane than the prevailing practice. The object of torture he defines very neatly as being to turn *semiplena* into *plena probatio*. For this proper *indicia* are necessary. He then proceeds to decide certain questions which had arisen, the most interesting of which deal with the nature of the sin of which the accused and the judge are guilty in particular instances. A judge sins gravely if he does not attempt all milder means of discovering truth before resorting to torture. He sins in a criminal cause, or in one of notable infamy, if he binds the accused by oath to tell the truth before there is proof against him. It is the same if without oath he uses threats, terror or exhibition of torments to confound the witness.[6] If any one, to avoid grave torments, charges himself with a capital crime, he does not sin mortally.[7] It was a doubtful question whether he sinned gravely in such a case. Escobar at an earlier date supported the morally dangerous view that an inquisitor may follow a probable opinion in ordering torture, relinquishing a more probable.[8]

England.—It is the boast of the common law of England that it never recognized torture as legal. One, perhaps the chief, reason for this position taken by the law is the difference of the nature of the procedure in criminal cases from that in general use in European countries. To use words more familiar in foreign jurisprudence, the English system is *accusatorial* as distinguished from *inquisitorial*. In the former the accuser has to prove guilt, in the latter the accused has to prove innocence. The common law of England has always shown itself averse from the inquisitorial system, and so (at least in theory) to the torture which may be regarded as an outcome of the system whose one end was to obtain a confession from the accused. The tendency of the small amount of statute law bearing on the subject is in the same direction. It was provided by Magna Carta, § 29, " that no free man . . . should be destroyed in any way unless by legal judgment of his equals or by the law of the land." On this Sir E. Coke comments, " No man destroyed, &c., that is, forejudged of life or limb, disinherited, or put to torture or death."[9] The act of 27 Hen. VIII. c. 4 enacted that, owing to the frequent escape of pirates in trials by the civil law, " the nature whereof is that before any judgment of death can be given against the offenders they must plainly confess their offence (which they will never do without torture or pains)," such persons should be tried by jury before commissioners under the Great Seal. Finally, the Bill of Rights provided that cruel and unusual punishments ought not to be inflicted. The opinions of the judges have been invariably against torture in theory, however much some of them may have been led to countenance it in practice. The strongest authority is the resolution of the judges in Felton's case (1628), " that he ought not by the law to be tortured by the rack, for no such punishment is known or allowed by our law."[10] In accordance with this are the opinions of Sir John Fortescue,[11] Sir Thomas Smith [12] and Sir E. Coke. The latter says, " As there is no law to warrant tortures in this land, nor can they be justified by any prescription, being so lately brought in."[13] In spite of all this, torture in criminal proceedings was inflicted in England with more or less frequency for some centuries, both as a means of obtaining evidence and as a part of the punishment. But it should be remarked that torture of the former kind was invariably ordered by the Crown or council, or by some tribunal of extraordinary authority, such as the Star Chamber, not professing to be bound by the rules of the common law. In only two instances was a warrant to torture issued to a common law judge.[14]

A licence to torture is found as early as the Pipe Roll of 34 Hen. II.[15] The Templars were tortured in 1310 by royal warrant addressed to the mayor and sheriffs of London.[16] In this case it is recorded that torture was unknown in England, and that no torturer was to be found in the realm.[17] A commission was issued concerning the tortures at Newgate in 1334.[18] The rack in the Tower is said to have been introduced by the duke of Exeter in the reign of Henry VI., and to have been thence called "the duke of Exeter's daughter."[19] In this reign torture seems to have taken its place as a part of what may be called extraordinary criminal procedure, claimed, and it may be said tacitly recognized, as exercisable by virtue of the prerogative, and continued in use down to 1640.[20] The infliction of torture gradually became more common under the Tudor monarchs. Under Henry VIII. it appears to have been in frequent use. Only two cases are recorded under Edward VI., and eight under Mary.[21] The reign of Elizabeth was its culminating point. In the words of Hallam, " the rack seldom stood idle in the Tower for all the latter part of Elizabeth's reign."[22] The varieties of torture used at this period are fully described by Dr Lingard,[23] and consisted of the rack, the scavenger's daughter,[24] the iron gauntlets or bilboes, and the cell called " Little Ease." The registers of the council during the Tudor and early Stuart reigns are full of entries as to the use of torture, both for state and for ordinary offences.[25] Among notable prisoners put to the torture were Anne Askew, the Jesuit Campion, Guy Fawkes[26] and Peacham (who was examined by Bacon " before torture, in torture and after torture ").[27] The prevalence of torture in Elizabeth's reign led to the well-known defence attributed to Lord Burghley, " A declaration of the favourable dealing of Her Majesty's commissioners appointed for the examination of certain traitors, and of tortures unjustly reported to be done upon them for matter of religion," 1583.[28] The use of torture in England being always of an extraordinary and extra-judicial nature, it is

[1] An edition was published at Rome in 1558, and a compendium at Lisbon in 1762, and by Marchena at Montpellier in 1821.

[2] It was by Father Masini, and went through numerous editions (complete or compendia) from 1558 to 1730. Among other manuals of practice were those of Carenas Caesar (1655), Morellet (1762).

[3] Llorente c. xiv.

[4] Among others were the gradual pouring of water drop by drop on a particular spot of the body, the *tormento de toca*, or pouring of water into a gauze bag in the throat, which gradually forced the gauze into the stomach, and the *péndola*, or swinging pendulum, so graphically described in one of Edgar Poe's tales.

[5] *Ordonnances des rois*, i. 346.

[28] Lord Somers's *Tracts*, i. 189.

comparatively certain that it could hardly have been applied with that observation of forms which existed in countries where it was regulated by law. There were no rules and no responsibility beyond the will of the Crown or council. This irresponsibility is urged by Selden[1] as a strong objection to the use of torture. The main differences between the infliction of torture in England and on the continent of Europe seem to be that English lawyers made no distinction of those liable to it, never allowed torture of witnesses, and elaborated no subtle rules as to *plena* and *semiplena probatio*.

So far of what may be called torture proper, to which the common law professed itself a stranger. There were, however, cases fully recognized by the common law which differed from torture only in name. The *peine forte et dure* was a notable example of this. If a prisoner stood mute of malice instead of pleading, he was condemned to the *peine*, that is, to be stretched upon his back and to have iron laid upon him as much as he could bear, and more, and so to continue, fed upon bad bread and stagnant water through alternate days until he pleaded or died.[2] It was abolished by 12 Geo. III. c. 20. 7 and 8 Geo. IV. c. 28 enacted that a plea of "not guilty" should be entered for a prisoner so standing mute. A case of *peine* occurred as lately as 1726. At times tying the thumbs with whip-cord was used instead of the *peine*. This was said to be a common practice at the Old Bailey up to the 18th century.[3] In trials for witchcraft the legal proceedings often partook of the nature of torture, as in the throwing of the reputed witch into a pond to see whether she would sink or swim, in drawing her blood,[4] and in thrusting pins into the body to try to find the insensible spot. Confessions, too, appear to have been often extorted by actual torture, and torture of an unusual nature, as the devil was supposed to protect his votaries from the effects of ordinary torture.

Torture as a part of the punishment existed in fact, if not in name, down to a very recent period. Mutilation as a punishment appears in some of the pre-Conquest codes, such as those of Alfred, Æthelstan and Canute, in the laws attributed to William the Conqueror and in the assize of Northampton (1176). Bracton, who does not notice torture as a means of obtaining evidence, divides corporal punishment into that inflicted with and without torture.[5] Later instances are the punishment of burning to death inflicted on heretics under the Six Articles (31 Hen. VIII. c. 14) and other acts, and on women for petit treason (abolished by 30 Geo. III. c. 48), the mutilation inflicted for violence in a royal palace by 33 Hen. VIII. c. 12, the punishment for high treason, which existed nominally until 1870, the pillory (abolished by 7 Will. IV. and 1 Vict. c. 23), the stocks, branks and cucking-stool, and the burning in the hand for felony (abolished by 19 Geo. III. c. 74). Corporal punishment now exists only in the case of juvenile offenders and of robbery with violence. It was abolished in the army by the Army Act 1881.[6] Cruelty in punishment did not entirely cease in prisons even after the Bill of Rights. See such cases as *R.* v. *Huggins*, 17 *State Trials*, 298; *Castell* v. *Bambridge*, 2 *Strange's Rep.* 856.

Scotland.—Torture was long a recognized part of Scottish criminal procedure, and was acknowledged as such by many acts and warrants of the Scottish parliament and warrants of the Crown and the privy council. Numerous instances occur in the *Register of the Privy Council*.[7] Two acts in 1649 dealt with torture; one took the form of a warrant to examine witnesses against William Barton by any form of probation,[8] the other of a warrant to a committee to inquire as to the use of torture against persons suspected of witchcraft.[9] The judges in 1689 were empowered by the estates to torture Chiesly of Dalrye, charged with the murder of the lord president Lockhart, in order to discover accomplices. In the same year the use of torture without evidence or in ordinary cases was declared illegal in the Claim of Right. The careful wording of this will be noticed: it does not object to torture altogether, but reserves it for cases where a basis of evidence had already been laid, and for crimes of great gravity, thus admitting the dangerous principle, founded on Roman law, that the importance of the crime is a reason for departing from the ordinary rules of justice. However great the crime, it is no more certain than in the case of a crime of less gravity that the person accused was the person who committed it. A warrant issued in the same year to put to the torture certain persons accused of conspiring against the government, and also certain dragoons suspected of corresponding with Lord Dundee. In 1690 an act passed reciting the torture of William Carstares, a minister, in 1683, and re-establishing his competency as a witness.[10] The last warrant appears to be one in 1690 for torturing a man accused of rape and murder. In 1708 torture in Scotland was finally abolished by 7 Anne c. 21, s 5. Many details of the tortures inflicted will be found in Pitcairn's *Criminal Trials*, the introduction to J. Maclaurins' *R. Criminal Cases* and J. H. Burton's *Narratives from Criminal Trials*. Among other varieties—the nature of some of them can only be guessed—were the rack, the pilniewinkis, the boot,[11] the caschie-laws, the lang irnis, the narrow-bore, the pynebankis, and worst of all, the waking, or artificial prevention of sleep.[12] The ingenuity of torture was exercised in a special degree on charges of witchcraft, notably in the reign of James VI., an expert both in witchcraft and in torture. The act of 1649 already cited shows that the principle survived him. Under the government of the dukes of Lauderdale and York torture as a practice in charges of religious and political offences reached its height. "The privy council was accustomed to extort confessions by torture; that grim divan of bishops, lawyers and peers sucking in the groans of each undaunted enthusiast, in hope that some imperfect avowal might lead to the sacrifice of other victims, or at least warrant the execution of the present."[13] With such examples before them in the law, it is scarcely to be wondered at that persons in positions of authority, especially the nobility, sometimes exceeded the law and inflicted torture at their own will and for their own purposes. There are several instances in the *Register of the Privy Council* of suits against such persons, *e.g.* against the earl of Orkney, in 1605, for putting a son of Sir Patrick Bellenden in the boots.

Ireland seems to have enjoyed comparative immunity from torture. It was not recognized by the common or statute law, and the cases of its infliction do not appear to be numerous. In 1566 the president and council of Munster, or any three of them, were empowered to inflict torture, "in cases necessary, upon vehement presumption of any great offence in any party committed against the Queen's Majesty."[14] In 1583 Hurley, an Irish priest, was tortured in Dublin by "toasting his feet against the fire with hot boots."[15] In 1627 the lord deputy doubted whether he had authority to put a priest named O'Cullenan to the rack. An answer was returned by Lord Killultagh to the effect that "you ought to rack him if you saw cause and hang him if you found reason."[16] The latest case of *peine forte et dure* seems to have been in 1740.

British Colonies and Dependencies.—The infliction of torture in any British colony or dependency has usually been regarded as contrary to law, and ordered only by arbitrary authority. It is true that in the trial of Sir Thomas Picton in 1806, for subjecting, while governor of Trinidad, a woman named Luisa Calderon to the torture of the picquet,[17] one of the grounds of defence was that such torture was authorized by the Spanish law of the island, but the accused was convicted in spite of this defence, and the final decision of the court of king's bench, in 1812, decreeing a respite of the defendant's recognizances till further order, was perhaps not so much an affirmation of the legality in the particular instance as the practical expression of a wish to spare an eminent public servant.[18] As to India, the second charge against Warren Hastings was extortion from the begums of Oude by means of the torture of their servants.[19] In the present Indian Penal Code and Evidence Acts there are provisions intended, as Sir James Stephen says,[20] to prevent the practice of torture by the police for the purpose of extracting confessions from persons in their custody.[21] In Ceylon torture, which had been allowed under the Dutch government, was expressly abolished by royal proclamation in 1799.

In the Channel Islands confessions of persons accused of witchcraft in the 17th century were frequently obtained by torture.[22]

United States.—One instance of the *peine forte et dure* is known. It was inflicted in 1692 on Giles Cory of Salem, who refused to plead when arraigned for witchcraft.[23] The constitution of the United States provides, in the words of the Bill of Rights, that cruel and unusual punishments are not to be inflicted.[24] This is repeated in the constitutions of most states. The infliction of cruel and unusual punishment by the master or officer of an American vessel on the high seas, or within the maritime jurisdiction of the United States, is punishable with fine or imprisonment, or both.[25] There have been a good many decisions on the question of cruel and unusual punishments; *e.g. Wilkerson* v. *Utah*, 99 U.S. Rep. 130;

Continental European States.—These fall into four main groups, the Latin, Teutonic, Scandinavian and Slav states respectively. The principles of Roman law were generally adopted in the first and second groups.

Latin States.—In France torture does not seem to have existed as a recognized practice before the 13th century. From that period until the 17th century it was regulated by a series of royal *ordonnances* at first of local obligation, afterwards applying to the whole kingdom. Torture was used only by the royal courts, its place in the seigneurial courts being supplied by the judicial combat. The earliest *ordonnance* on the subject was that of Louis IX. in 1254 for the reformation of the law in Languedoc. It enacted that persons of good fame, though poor, were not to be put to the question on the evidence of one witness.[1] Numerous other provisions were made between 1254 and 1670, when an *ordonnance* was passed under Louis XIV., which regulated the infliction of torture for more than a century. Two kinds were recognized, the *question préparatoire* and the *question préalable.* The first was used where strong evidence of a capital crime—strong, but of itself insufficient for conviction—was produced against the accused. The second was used to obtain a confession of accomplices after conviction. There was also a mitigated form called the presentment, in which the accused was simply bound upon the rack *in terrorem* and there interrogated. No person was exempt on the ground of dignity, but exemption was allowed to youths, old men, sick persons and others. Counsel for the accused were usually not allowed. The *question préparatoire* was abolished by royal decree in 1780, but in 1788 the parliaments refused to register a decree abolishing the *préalable.* But torture of all kinds was abolished by an *ordonnance* in 1789. The Declaration of Right in 1791 (art. viii.) affirmed that the law ought not to establish any punishments other than such as are strictly and evidently necessary. In modern law the *code pénal* enacts that all criminals shall be punished as guilty of assassination who for the execution of their crimes employ torture.[2] The code also makes it punishable to subject a person under arrest to torture.[3] The theory of *semiplena probatio* was worked out with more refinement than in other systems. In some parts of France not only were half-proofs admitted, but quarters and eighths of proofs.[4] Among the numerous cases of historical interest were those of the Templars in 1307, Villon about 1457, Dolet in 1546, the marquise de Brinvilliers in 1676 and Jean Calas in 1762.[5]

The law as it existed in Italy is contained in a long line of authorities chiefly supplied by the school of Bologna, beginning with the *glossatores* and coming down through the *post-glossatores*, until the system attained its perfection in the vast work of Farinaccius, written early in the 17th century, where every possible question that could arise is treated with a revolting completeness. One of the earliest jurists to treat it was Cino da Pistoia, the friend of Dante.[6] He treats it at no great length. With him the theory of *indicia* exists only in embryo, as they cannot be determined by law but must be at the discretion of the judge. Differing from Bartolus, he affirms that torture cannot be repeated without fresh *indicia.* The writings of jurists were supplemented by a large body of legislative enactments in most of the Italian states, extending from the constitutions of the emperor Frederick II. down to the 18th century. It is not until Bartolus (1314–1357) that the law begins to assume a definite and complete form. In his commentary on book xlviii. of the *Digest* he follows Roman law closely, but introduces some further refinements: *e.g.* though leading questions may not be asked in the main inquiry they are admissible as subsidiary. There is a beginning of classification of *indicia.* A very full discussion of the law is contained in the work on practice of Hippolytus de Marsiliis,[7] a jurist of Bologna, notorious, on his own admission, as the inventor of the torture of keeping without sleep. He defines the question as *inquisitio veritatis per tormenta et cordis dolorem*, thus recognizing the mental as well as the physical elements in torture. It was to be used only in capital cases and atrocious crimes. The works of Farinaccius and of Julius Clarus nearly a century later were of great authority from the high official positions filled by the writers. Farinaccius was procurator-general to Pope Paul V., and his discussion of torture is one of the most complete of any.[8] It occupies 251 closely printed folio pages with double columns. The length at which the subject is treated is one of the best proofs of the science to which it had been reduced. The chief feature of the work is the minute and skilful analysis of *indicia, fama, praesumptio*, and other technical terms. Many definitions of *indicium* are suggested, the best perhaps being *conjectura ex probabilibus et non necessariis orta, a quibus potest abesse veritas sed non verisimilitudo.* For every infliction of torture a distinct *indicium* is required. A single witness or an accomplice constitutes an *indicium.* But this rule does not apply where it is inflicted for discovering accomplices or for discovering a crime other than that for which it was originally inflicted. Torture may be ordered in all criminal cases, except small offences, and in certain civil cases, such as denial of a *depositum*, bankruptcy, usury, treasure trove, and fiscal cases. It may be inflicted on all persons, unless specially exempted (clergy, minors, &c.), and even those exempted may be tortured by command of the sovereign. There are three kinds of torture, *levis*, *gravis* and *gravissima*, the first and second corresponding to the ordinary torture of French writers, the last to the extraordinary. The extraordinary or *gravissima* was as much as could possibly be borne without destroying life. The judge could not begin with torture; it was only a *subsidium.* If inflicted without due course of law, it was void as a proof. The judge was liable to penalties if he tortured without proper *indicia*, if a privileged person, or if to the extent that death or permanent illness was the result. An immense variety of tortures is mentioned, and the list tended to grow, for, as Farinaccius says, judges continually invented new modes of torture to please themselves. Numerous casuistical questions are treated at length, such as, what kinds of reports or how much hearsay evidence constituted fame? Were there three or five grades in torture? Julius Clarus of Alessandria was a member of the council of Philip II. To a great extent he follows Farinaccius. He puts the questions for the consideration of the judge with great clearness. They are—whether (1) a crime has been committed, (2) the charge is one in which torture is admissible, (3) the fact can be proved otherwise, (4) the crime was secret or open, (5) the object of the torture is to elicit confession of crime or discovery of accomplices. The clergy can be tortured only in charges of treason, poisoning and violation of tombs. On the great question whether there are three or five grades, he decides in favour of five, viz. threats, taking to the place of torment, stripping and binding, lifting on the rack, racking.[9] Other Italian writers of less eminence have been referred to for the purposes of this article. The burden of their writings is practically the same, but they have not attained the systematic perfection of Farinaccius. Citations from many of them are made by Manzoni (see below). Among others are Guido de Suzara, Paris de Puteo, Aegidius Bossius of Milan, Casonus of Venice, Decianus, Follerius and Tranquillus Ambrosianus, whose works cover the period from the 13th to the end of the 17th century. The law depended mainly on the writings of the jurists as interpreters of custom. At the same time in all or nearly all the Italian states and colonies[10] the customary law was limited, supplemented, or amended by legislation. That a check by legislative authority was necessary appears from the glimpses afforded by the writings of the jurists that the letter of the law was by no means always followed. The earliest legislation after the Roman law seems to be the constitutions of the emperor Frederick II. for Sicily promulgated in 1231. Torture was abolished in Tuscany in 1786, largely owing to the influence of Beccaria, whose work first appeared in 1764, and other states followed, but the *puntale* or piquet seems to have existed in practice at Naples up to 1859.

Several instances of the torture of eminent persons occur in Italian history, such as Savonarola, Machiavelli, Giordano Bruno, Campanella. Galileo appears to have only been threatened with the *esame rigoroso.* The historical case of the greatest literary interest is that of the persons accused of bringing the plague into Milan in 1630 by smearing the walls of houses with poison. An analysis of the case was undertaken by Verri[11] and Manzoni,[12] and puts in a clear light some of the abuses to which the system led in times of popular panic. Convincing arguments are urged by Manzoni, after an exhaustive review of the authorities, to prove the groundlessness of the charge on which two innocent persons underwent the torture of the *canape*, or hempen cord (the effect of which was partial or complete dislocation of the wrist), and afterwards suffered death by breaking on the wheel. The main arguments, shortly stated, are these, all based upon the evidence as recorded, and the law as laid down by jurists. (1) The unsupported evidence of an accomplice was treated as an *indicium* in a case not one of those exceptional ones in which such an *indicium* was sufficient. The evidence of two witnesses or a confession by the accused was necessary to establish a remote *indicium*, such as lying. (2) Hearsay evidence was received when primary evidence was obtainable. (3) The confession made under torture was not ratified afterwards. (4) It was made in consequence of a promise of impunity. (5) It was of an impossible crime.

[4] See Pollock and Maitland, ii. 658, note.

[5] On the French system generally see Imbertus, *Institutiones forenses gallicae* (Utrecht, 1649); N. Weiss, *La Chambre ardente, 1540–1550* (Paris, 1889). A large number of authorities deal mainly with the *ordonnance* of 1670; Muyart de Vouglans, *Inst. crim.* (Paris, 1767), and Jousse, *Traité de la justice crim.* (Paris, 1771), are examples. F. Siegneux de Correvon, *Essai sur l'usage, l'abus, et les inconvéniens de la torture* (Geneva, 1768), is one of the opponents of the system.

In Spain, as in Italy, the law depended partly on the writings of jurists, partly on legislation. Roman law was carried through the Visigothic Code and the *Fuero juzgo*[1] (which repeats it almost word for word) down to the *Siete partidas*.[2] This treatise, compiled by Alphonso the Wise about 1243, but not promulgated till 1256, amended the previously existing law in the direction of greater precision. Torment is defined as a manner of punishment which lovers of justice use, to scrutinize by it the truth of crimes committed secretly and not provable in any other manner. Repetition was allowed in case of grave crimes. There were the usual provisions for the infliction of torture only by a judge having jurisdiction, and for the liability of the judge for exceeding legal limits. Subsequent codes did little more than amend the *Partidas* in matters of procedure. Torture is not named in the *Ordenanzas reales* of Ferdinand and Isabella (1485). The *Nueva recopilacion* of Philip II. enacted that torture was to be applied by the *alcaldes* on due sentence of the court—even on *hidalgos* in grave crimes—without regard to alleged privilege or custom. In the *Novisima recopilacion* of 1775 the only provisions on the subject are that the *alcaldes* are not to condemn to torment without preceding sentence according to law, and that *hidalgos* are not to be tormented or suffer infamous punishment. In Aragon, while it was an independent state, torture was not in use to the same extent as in other parts of Spain. It was abolished in the 13th century by the General Privilege of 1283 except in the case of vagabonds charged with coining. A statute of 1335 made it unlawful to put any freeman to the torture.[3] On the other hand, the Aragonese nobility had a power, similar to the *peine forte et dure*, of putting a criminal to death by cold, hunger and thirst.[4] The jurists dealing with the subject are not as numerous as in Italy, no doubt because Italian opinions were received as law in all countries whose systems were based on Roman law.[5] Some of the Italian jurists too, like Clarus, were at that same time Spanish officials. The earliest Spanish secular jurist appears to be Suarez de Paz.[6] According to him the most usual tortures in Spain were the water and cord, the pulley or *strappado*, the hot brick, and the *tablillas*, or thumbscrew and boot combined. Three was the greatest number of times that any torture could be applied. It might be decreed either on demand of the accuser or at will of the judge. The Roman rule of beginning with the weakest was amplified into a series of regulations that a son was to be put to the question before a father, a woman before a man, &c. The fullest statement of Spanish law is to be found in the work of Antonio Gomez, a professor at Salamanca.[7] With him no exceptions apply in charges of *laesa majestas divina* or *humana*. A judge is liable to different punishment according as he orders torture *dolose* or *culpabiliter*. Differing from Hippolytus de Marsiliis, Gomez holds that the dying accusation of a murdered man is not an *indicium*. A confession on insufficient *indicia* is void. His division of torture into *tortura actualis* and *terror propinquus* is the same as that of the French jurists into torture and presentment. The conclusions of the ecclesiastical writers of Spain, such as Eymerico and Simancas, were accepted wholly or partially by the secular writers, such as Alvarez de Velasco,[8] and the Peruvian, Juan de Hevia Bolaños,[9] who points out differences in the ecclesiastical and secular systems, *e.g.* the former brought up the accused for ratification in three days, the latter in twenty-four hours. A good deal of the Spanish law will be found in the proceedings against Sir Thomas Picton (see above). Torture in Spain seems to have been inflicted on Jews to an extraordinary extent, as it was also in Portugal, where the latest legislation as to torture seems to be of the year 1678. In 1790 it had become obsolete,[10] and in a work on criminal procedure four years later it is only referred to for the purpose of stating that when it did exist it was *realis* or *verbalis*.[11]

Teutonic States.—Germany (including Austria) is distinguished by the possession of the most extensive literature and legislation on the subject. The principal writers are Langer, von Rosbach and von Boden. In addition may be cited the curious *Layenspiegel* of Ulrich Tengler (1544), and the works of Remus, Casonus and Carpzow.[12] Legislation was partly for the empire, partly for its component states. Imperial legislation dealt with the matter in the Golden Bull (1356), the Ordinance of Bamberg (1507), the Carolina (1532)[13] and the *Constitutio criminalis theresiana* (1768).[14] The Carolina followed the usual lines, the main difference being that the infliction must be in the presence of two *scabini* and a notary, who was to make a detailed record of the proceedings. The code of Maria Theresa defines torture as "a subsidiary means of eliciting truth." It could be applied only in cases where condemnation would have involved capital or severe corporal punishment. The illustrated edition was suppressed by Prince Kaunitz a few days after its appearance. Torture was formally abolished in the empire in 1776. In Prussia it was practically abolished by Frederick the Great in 1740, formally in 1805. Even before its abolition it was in use only to discover accomplices after conviction.[15] In some other states it existed longer, in Baden as late as 1831. It was carried to excess in Germany, as in the Netherlands and Scotland in charges of witchcraft.

The Netherlands.—The principal legislative enactment was the code of criminal procedure promulgated by Philip II. in 1570 and generally known as the *Ordonnance sur le style*.[16] One of its main objects was to assimilate the varieties of local custom, as the *Nueva recopilacion* had done in Spain three years earlier. The French *ordonnance* of 1670 is probably largely based on it. In spite of the attempt of the ordinance to introduce uniformity, certain cities of Brabant, it is said, still claimed the privilege of torturing in certain cases not permitted by the ordinance, *e.g.* where there was only one witness.[17]

The law of 1670 continued to be the basis of criminal procedure in the Austrian Netherlands until 1787. In the United Provinces it was not repealed until 1798. The principal text-writers are Damhouder,[18] van Leeuwen[19] and Voet. Van Leeuwen lays down as a fundamental principle that no one was to be condemned to death without confession, and such confession, if attainable in no other way, ought to be elicited by torture. Witnesses could be tortured only if they varied on confrontation. One of the *indicia* not always recognized by jurists was previous conviction for a similar crime. Voet's commentary *ad Pandectas*[20] is interesting for its taking the same view as St Augustine as to the uselessness of torture, and compares its effect with that of the trial by battle. At the same time he allows it to be of some value in the case of very grave crimes. The value of torture was doubted by others as well as Voet, *e.g.* by A. Nicholas[21] and by van Essen.[22] At the same time a writer was found to compose a work on the unpromising subject of the rack.[23]

Scandinavian Countries.—There is a notice of torture in the Icelandic Code known as the Grágás (about 1119). Judicial torture is said to have been introduced into Denmark by Valdemar I. in 1157.[24] In the code of Christian V. (1683) it was limited to cases of treason.[25] It was abolished by the influence of Struensee in 1771, but notwithstanding this he was threatened with it, though it was not actually inflicted, before his execution in 1772. In Sweden torture never existed as a system, and in the code of 1734 it was expressly forbidden.[26] It was however occasionally inflicted, as in England, by extrajudicial authorities, called secret committees.

[4] Du Cange, *s.v. Fame necare.*

[5] In all the Latin countries the idea of torture had become a commonplace. The dramatists contain frequent allusions to it. In Lope de Vega's *El Perro del hortelano* ("The Dog in the Manger"), one of the characters says, "Here's a pretty inquisition!" to which the answer is, "The torture will be next applied." Molière and Racine both make use of it. In *L'Avare*, act iv. sc. 7, Harpagon threatens to put his whole household to the question. In *Les Plaideurs* Dandin invites Isabelle to see *la question* as a mode of passing an hour or two. In England Bacon (Essay lvi.) says, "There is no worse torture than the torture of laws." The same idea occurs again in the *Advancement of Learning*, viii. 3, 13, "It is a cruel thing to torture the laws that they may torture men."

The "cave of roses," where reptiles were kept for the purpose of torture, was closed by Gustavus III. in 1772.

Slav Countries.—The earliest mention of torture seems to be that of the mutilation provided for certain offences by the code of Stephen Dushan in 1349. In Russia torture does not occur in the recensions of the earlier law. It was possibly of Tatar origin, and the earliest mention of it in an official document is probably in the *Sudebnik* of Ivan the Terrible (1497). In the ordinance of 1556 there are elaborate regulations, which one learns from history were not always observed in periods of political disturbance, and torture seems to have been used even as a means of enforcing payment of debts. The reaction begins with Peter the Great and culminates with Catharine II., who was largely influenced by the opinions of Beccaria and Voltaire. In the instructions to the commission for framing a criminal code (1766), it is declared that all punishments by which the body is maimed ought to be abolished,[1] and that the torture of the rack violates the rules of equity and does not produce the end proposed by the laws.[2] It was formally abolished by Alexander I. in 1801, and in 1832 the *Svod Zakonov* subjected to penalties any judge who presumed to order it. But even as late as 1847 it seems to have been inflicted in one or two exceptional cases.[3]

AUTHORITIES.—For England Jardine's is still the standard work. Much general information and numerous authorities will be found in Lipenius, *Bibliotheca realis Juridica*, *s.v.* "Tortura" (Frankfort, 1679), and in the more modern work of J. Helbing, *Die Tortur* (Berlin, 1902). For those who can obtain access to it the catalogue issued at the sale of M. G. Libri (1861) is valuable. He had collected most of the books on the subject. There are several publications dealing with cases of individuals in addition to the numerous ones on witchcraft trials, *e.g.* those of William Lithgow, the Amboyna case, Dellon and Van Halen. Lithgow's story has been republished (Glasgow, 1907). (J. W.)

TORUS, a Latin word, meaning a round swelling or protuberance, applied to a convex moulding in architecture, which in section is generally a semicircle. The earliest examples are found in Egypt, where it was carried up the angles of the pylon and temple walls and horizontally across the same. Its most frequent employment is in the bases of columns; in the Roman Doric order being the lowest moulding; in the Ionic orders there are generally two torus mouldings separated by a scotia with fillets. Both in Greek and Roman bases sometimes the torus is elaborately carved. (See MOULDING.)

TORZHOK, a town of Russia, in the government of Tver, on the river Tvertsa, 21 m. by rail S.W. of the Likhoslavl, station of the St Petersburg & Moscow railway. Pop. (1900), 15,119. It dates from the 11th century, and the name (market-place) shows that this dependency of Novgorod was a commercial centre. It was fortified with a stone wall, which only partially protected it from the attacks of Mongols, Lithuanians and Poles. Torzhok is celebrated in Russia for its embroidered velvet and embroidered leather-work, for the manufacture of travelling bags, and for its trade in corn and flour.

TOSCANELLA (anc. *Tuscana*, *q.v.*), a town of the province of Rome, Italy, 15 m. N.E. of Corneto by road, 545 ft. above sea-level. Pop. (1901), 4839. The medieval walls with their towers are still preserved. On the ancient citadel hill is the Romanesque church of S. Pietro, belonging to four different periods—739, 1093 (the date of the reconstruction of the crypt), the middle of the 12th and the end of the 12th century. It has the shape of a Roman basilica, with a nave and two aisles and one apse. The elaborate façade with its rose window also belongs to the 12th century. S. Maria in the valley below dates from 1050 to 1206, and has a similar façade and a massive square campanile. In the town are two other Romanesque churches.

See G. T. Rivoira, *Origini dell' architettura Lombarda* i. 146 (Rome 1901).

TOSTIG (d. 1066), earl of Northumbria, was a son, probably the third, of Earl Godwine, and in 1051 married Judith, sister or daughter of Baldwin V., count of Flanders. In the year of his marriage he shared the short exile of his father, returning with him to England in 1052, and became earl of Northumbria after the death of Earl Siward in 1055. He was very intimate with his brother-in-law, Edward the Confessor, and in 1061 he visited Pope Nicholas II. at Rome in the company of Aldred, archbishop of York. By stern and cruel measures Tostig introduced a certain amount of order into the wild northern district under his rule; this severity made him exceedingly unpopular, and in 1065 Northumbria broke into open revolt. Declaring Tostig an outlaw and choosing Morkere in his stead, the rebels marched southwards and were met at Oxford by Earl Harold, who, rather against the will of the king, granted their demands. Tostig sailed to Flanders and thence to Normandy, where he offered his services to Duke William, who was related to his wife and who was preparing for his invasion of England. He then harried the Isle of Wight and the Kentish and Lincolnshire coasts, and, after a stay in Scotland and possibly a visit to Norway, joined another invader, Harald III. Hardrada, king of Norway, in the Tyne. Together they sailed up the Humber and at Gate Fulford, near York, defeated Earls Morkere and Edwine and entered York. But Harold, now king, was hurrying to the north. Taking the Norwegians by surprise at Stamford Bridge he destroyed their army on the 25th of September 1066, and in this battle both Tostig and the king of Norway were slain. Tostig's two sons appear to have taken refuge in Norway, and his widow Judith married Welf, duke of Bavaria.

See E. A. Freeman, *The Norman Conquest*, vols. ii. and iii. (1870–1876).

TOTANA, a town of eastern Spain, in the province of Murcia, on the Lorca-Murcia railway. Pop. (1900), 13,703. The town, which consists of two parts, the Barrio de Sevilla and Barrio de Triana, contains several handsome public buildings, among them the church of Santiago, with its three naves. Water is conveyed to Totana from the Sierra de Espuña by an aqueduct 7 m. long. Saltpetre is obtained among the hills, and there is a thriving trade in wheat, oranges, olives, almonds, and wine from the Sangonera valley. Other industries are the manufacture of linen, leather and the earthenware jars called *tinajas*, which are used for the storage of oil and wine.

TOTEMISM. The word "totem" is used in too many varying senses by students of early society and religion. The term came into the English language in the form of "totam," through a work of 1791, by J. Long, an interpreter between the whites and the Red Indians of North America.[4] Long himself seems to have used the word to denote the protective familiar, usually an animal, which each Indian selected for himself, generally through the monition of a dream during the long fast of lads at their initiation. Such selected (or, when bestowed by medicine-men or friends, "given") totems are styled "personal totems" and have no effect in savage law, nor are they hereditary, with any legal consequences.

In stricter terminology "totem" denotes the object, generally of a natural species, animal or vegetable, but occasionally rain, cloud, star, wind, which gives its name to a *kindred* actual or supposed, among many savages and barbaric races in America, Africa, Australia and Asia and the isles. Each child, male or female, inherits this name, either from its mother ("female descent") or from its father ("male descent"). Between each person and his or her name-giving object, a certain mystic *rapport* is supposed to exist. Where descent wavers, persons occasionally have, in varying degrees, the totems of both parents.

Religious Aspect of the Totem.—As a rule, by no means invariable, the individual may not kill or eat the name-giving object of his kin, except under dire necessity; while less usually it is supposed to protect him and to send him monitory dreams. This is the "religious" or semi-religious aspect of the totem, or this aspect is, by some students, called "religious."

We also hear of customs of burying and lamenting dead animals which are regarded with reverence by this or that "family," or "clan." This custom is reported among the Samoans, and one "clan" was said to offer first-fruits to its sacred animal, the eel; while the "clan" that revered the pigeon kept and fed a tame specimen.[5] But in Samoa, though the sacred animals of "clans" or "families" are, in all probability, survivals of totemism, they are now regarded by the people as the vehicles

of "clan" or "family" gods, and therefore receive honours not paid to the hereditary totems of Australia and North America, which have nothing godlike. It is to be presumed that "totem dances" in which some Australian tribes exhibit, in *ballets d'action*, the incidents of a myth concerning the totem, are, in a certain sense, "religious"; when they are not magical, and intended to foster and fertilize the species, animal or vegetable or other to which the totem belongs.

The magical performances for the behoof of the totem creatures may be studied in the chapters on "Intichiuma" in Messrs Spencer and Gillen's *Native Tribes of Central Australia*, and *Native Tribes of Northern Australia*. Among the many guesses at the original purpose of totemism, one has been that the primal intention of totem sets of human beings was to act as magical co-operative stores for supplying increased quantities of food to the tribe. But this opinion has gone the way of other conjectures. The "religious" status of the totem is lowest among peoples where its influence on social regulations is greatest, and vice versa, a topic to which we recur.

There are also various rites, in various tribes, connecting the dead man with his totem at his funeral; perhaps at his initiation, when a boy, into the esoteric knowledge and rules of his tribe. Men may identify themselves with their totems, or, mark themselves as of this or that totem by wearing the hide or the plumage of the bird or beast, or by putting on a mask resembling its face. The degree of "religious" regard for the revered object increases in proportion as it is taken to contain the spirit of an ancestor or to be the embodiment of a god: ideas not found among the most backward savages.

The supreme or superior being of low savage religion or mythology is never a totem. He may be able, like Zeus in Greek mythology, to assume any shape he pleases; and in the myths of some Australian tribes he ordained the institution of totemism. Byamee, among the Euahlayi tribe of north-west New South Wales, had all the totems in him, and when he went to his paradise, Bullimah, he distributed them, with the marriage rules, among his people.[1] In other legends, especially those of central and northern Australia, the original totem creatures, animal in form, with bestial aspect, were developed in a marine or lacustrine environment, and from them were evolved the human beings of each totem kin. The rule of non-intermarriage within the totem was, in some myths, of divine institution; in others, was invented by the primitive wandering totemic beings; or was laid down by the wisdom of mere men who saw some unknown evil in consanguine unions. The strict regard paid to the rule may be called "religious"; in so far as totemists are aware of no secular and social *raison d' être* of the rule it has a mysterious character. But whereas to *eat* the totem is sometimes thought to be automatically punished by sickness or death, this danger does not attach to *marriage* within the totem save in a single known case. The secular penalty alone is dreaded; so there seems to be no religious fear of offending a superior being, or the totem himself: no tabu of a mystic sort.

Social Aspect of the Totem.—The totem has almost always a strong influence on or is associated with marriage law, and except in the centre of Australia, and perhaps in the little-known West, men and women of the same totem may not intermarry, "however far apart their hunting grounds," and though there is no objection on the score of consanguinity.

This is the result, in Australia, of the custom, there almost universal, which causes each individual to belong, by birth, to one or other of the two main exogamous and intermarrying divisions of the tribe (usually called "phratries"). The phratries (often known by names of animals, as Eagle Hawk and Crow, Crow and White Cockatoo) contain each a number of totem kins, as Dog, Wild Cherry, Wombat, Frog, Owl, Emu, Kangaroo, and so on, and (except among the Arunta "nation" of five tribes in Central Australia) the same totem kin never occurs in both phratries. Thus as all persons except in the Arunta nation, marry out of their own phratry, none can marry into his or her totem kin.

[1] Mrs Langloh Parker, *The Euahlayi Tribe*.

In some parts of North America the same rule prevails, with this peculiarity that the phratries, or main exogamous divisions, are not always two, as in Australia, but, for example, among the Mohegans three—Wolf, Turtle, and Turkey.[2] In Wolf all the totems are quadrupeds; under Turtle they are various species of turtles and the yellow eel; and under Turkey all the totems are birds.

Clearly this ranking of the totems in the phratries is the result of purposeful design, not of accident. Design may also be observed in such phratries of Australian tribes as are named after animals of contrasted colours, such as White Cockatoo and Crow, Light Eagle Hawk and Crow. It has been supposed by Mr J. Mathew, Père Schmidt and others that these Australian phratries arose in an alliance with *connubium* between a darker and a lighter race.[3] But another hypothesis is not less probable; and as we can translate only about a third of Australian phratry names, conjecture on this subject is premature.

Both in Australia and America the animals, as Eagle Hawk and Crow, which give their names to the phratries, are almost always totem kins within their own phratries.[4]

The Moquis of Arizona are said to have ten phratries, by Captain Ulick Bourke in his *Snake Dance of the Moquis*, but possibly he did not use the term "phratry" in the sense which we attach to it.

Among the Urabunna of Southern Central Australia, and among the tribes towards the Darling River, a very peculiar rule is said to prevail. There are two phratries, and in each are many totem kins, but each totem kin may intermarry with only one totem kin which must be in the opposite phratry.[5] Thus there are as many exogamous divisions as there are totems in the tribes, which reckon descent in the female line; children inheriting the mother's totem only. Corroboration of these statements is desirable, as the tribes implicated are peculiarly "primitive," and theirs may be the oldest extant set of marriage rules.

The existence of two or more main exogamous divisions, named or unnamed, is found among peoples where there are either no totem kins, or where they have fallen into the background, as in parts of Melanesia, among the Todas and Meitchis of India and the Wanika in East Africa.[6]

An extraordinary case is reported from South Australia where people must marry in their own phratry, while their children belong to the opposite phratry.[7] This awaits corroboration.

We now see some of the numerous varieties which prevail in the marriage rules connected with the totems. Even among a tribe whose members, it is reported, may marry into their own phratries, it appears that they must not marry within their own totem kins. This is, indeed, the rule wherever totemic societies are found in anything approaching to what we deem their most archaic constitution as in south-east Australia and some tribes of North America.

Exogamy: The Arunta Abnormality.—Meanwhile, in Central Australia, in the Arunta "nation," the rule forbidding marriage within the totem kin does not exist. Totems here are not, as everywhere else, inherited from either parent, but a child is of what we may call "the local totem" of the place where its mother first became conscious of its life within her. The idea is that the spirits of a primal race, in groups each of one totem only ("Alcheringa folk"), haunt various localities; or spirits (*ratapa*) emanating from these primal beings do so; they enter into passing married women, and are incarnated and born again.[8]

[8] It is necessary to state here the sources of our information about the central, north, north-western and south-eastern forms of

Thus if a woman, whatever her own totem, and whatever her husband's may be, becomes conscious of her child's life in a known centre of Wild Cat spirits, her child's totem is Wild Cat, and so with all the rest.

As a consequence, a totem sometimes here appears in what the people call the "wrong" (*i.e.* not the original) exogamous division; and persons may marry within their own totem name, if that totem be in the "right" exogamous division, which is not theirs. Each totem spirit is among the Arunta associated with an amulet or *churinga* of stone; these are of various shapes, and are decorated with concentric circles, spirals, *cupules*, and other archaic patterns. These amulets are only used in this sense by the Arunta nation and their neighbours the Kaitish, "and it is this idea of spirit individuals associated with *churinga* and resident in certain definite spots that lies at the root of the present totemic system of the Arunta," says Messrs Spencer and Gillen.[1] Every Arunta born incarnates a pre-existent primal spirit attached to one of the stone *churinga* dropped by primal totemic beings, all of one totem in each case, at a place called an *oknanikilla*. Each child belongs to the totem of the primal beings of the place, where the mother became aware of the child's life.

Thus the peculiar causes which have produced the unique Arunta licence of marrying within the totem are conspicuously obvious.

Contradictory Theories about the Arunta Abnormal Totemism.—At this point theories concerning the origin of totemism begin to differ irreconcilably. Mr Frazer, Mr Spencer, and, apparently Dr Rivers, hold that, in Australia at least, totemism was originally "conceptional." It began in the belief by the women that pregnancy was caused by the entrance into them of some spirit associated with a visible object, usually animal or vegetable; while the child born, in each case, was that object. Hence that class of objects was tabued to the child; was its totem, but such totems were not hereditary.

Next, for some unknown reason, the tribes were divided into two bodies or segments. The members of segment A may not intermarry; they must marry persons of segment B, and vice versa. Thus were evolved the primal forms of totemism and exogamy now represented in the law of the Arunta nation alone. Here, and here alone, marriage within the totem is permitted. The theory is, apparently, that, in all other exogamous and totemic peoples, totems had been, for various reasons, made hereditary, before exogamy was enforced by the legislator in his wisdom. Thus, all over the totemic world, except in the Arunta nation, the method of the legislator was simply to place one set of totem kins in tribal segment A, and the other in segment B, and make the segments exogamous and intermarrying. Thus it was impossible for any person to marry another of the same totem. This is the theory of Mr Frazer.

Upholders of the contradictory system maintain that the Arunta nation has passed through and out of the universal and normal system of hereditary and exogamous totemism into its present condition, by reason of the belief that children are incarnations of pre-existing animal or vegetable spirits, *plus* the unique Arunta idea of the connexion of such spirits with their stone *churinga*. Where this combination of the two beliefs does not occur, there the Arunta non-hereditary and non-exogamous totemism does not occur. It would necessarily arise in any normal tribe which adopted the two Arunta beliefs, which are not "primitive."

Arguments against Mr Frazer's Theory.—There was obviously a time, it is urged, when all totems were, as everywhere else,

totemism. About the central Arunta tribe with its neighbours, the Urabunna, we have the evidence very carefully collected by Mr Gillen, a protector of the aborigines, and Professor Baldwin Spencer (*Native Tribes of Central Australia*). Concerning the peoples north from the centre to the Gulf of Carpentaria, the same scholars furnish a copious account in their *Northern Tribes*. These two explorers had the confidence of the blacks; witnessed their most secret ceremonies, magical and initiatory; and collected their legends. Their books, however, contain no philological information as to the structure and interrelation of the dialects, information which is rarely to be found in the works of English observers in Australia. As far as appears, the observers conversed with the tribes only in "pidgin English." If this be the case that *lingua franca* is current among some eighteen central-northern tribes speaking various native dialects. We are told nothing about the languages used in each case; perhaps the Arunta men who accompanied the expedition arranged a system of interpreters.

For the Dieri tribe, neighbours of the Urabunna, we have copious evidence in *Native Tribes of South-East Australia* by the late Mr A. W. Howitt, who studied the peoples for forty years; was made free of their initiatory ceremonies; and obtained intelligence from settlers in regions which he did not visit. We have also legends with Dieri texts and translations from the Rev. Mr Siebert, a missionary among the Dieri. That tribe appears now to exist in a very dwindled condition under missionary supervision. The accounts of tribes from the centre to the south-east by Mr R. E. Mathew, are scattered in many English, Australian and American learned periodicals. Mr Mathew has given a good deal of information about some of the dialects. His statements as to the line of descent and on other points among certain tribes are at variance with those of Messrs Spencer and Gillen (see an article by Mr A. R. Brown in *Man*, March 1910). Mr Mathew, however, does not enable us to test the accuracy of his informants among the northern tribes, which is unfortunate. For the Aranda (or Arunta) of a region apparently not explored by Messrs Spencer and Gillen, and for the neighbouring Loritja tribe, we have *Die Aranda und Loritja Stämme*, two volumes by the Rev. C. Strehlow (Baer, Frankfurt am Main, 1907, 1908). Mr Strehlow is a German missionary who, after working among the Dieri and acquiring their language, served for many years among a branch of the Arunta (the Aranda), differing considerably in dialect, myths and usages from the Arunta of Messrs Spencer and Gillen. In some points, for example as to the primal ancestors and the spirits diffused by them for incarnation in human bodies, the Aranda and Loritja are more akin to the northern tribes than to Mr Spencer's Arunta. In other myths they resemble some south-eastern tribes reported on by Mr Howitt. Unlike the Arunta of Messrs Spencer and Gillen, but like the Arunta described by Mr Gillen earlier in *The Horn Expedition*, they believe in "a magnified non-natural man," Altjira, with a goose-foot, dwelling in the heavens. Unlike the self-created Atnatu of the Kaitish of Messrs Spencer and Gillen, he is not said to have created things, or to take any concern about human beings, as Atnatu does in matters of ceremonial. Mr Strehlow gives Aranda and Lortija texts in the original, with translations and philological remarks.

Mr Frazer, in his *Totemism*, makes no use of Mr Strehlow's information (save in a single instance). To us it seems worthy of study. His reason for this abstention is that, in a letter to him (Melbourne, March 10, 1908), Mr Spencer says that for at least twenty years the Lutheran Missions have taught the natives "that altjira means 'god'; have taught that their sacred ceremonies and secular dances are 'wicked'; have prohibited them, and have never seen them. Flour and tobacco, &c., are only given to natives who attend church and school. Natives have been married who, according to native customary law, belong to groups to which marriage is forbidden. For these reasons Mr Frazer cannot attempt "to filter the native liquor clear of its alien sediment," (*Totemism*, i. 186, note 2).

Against this we may urge that, as regards the goose-footed sky-dweller, Mr Strehlow reports less of his active interest in human affairs than Mr Gillen does concerning his "Great Ulthaana of the heavens" among the Arunta. Mr Strehlow's being, Altjira, has a name apparently meaning "mystic" or sacred, which is applied to other things, for example to the inherited maternal totem of each native. His names for Altjira (god) and for the totemic ancestors (totem gods), are inappropriate, but may be discounted. Many other tribes who *are* discussed by Mr Frazer have been long under missionary influence as well as the Aranda. According to Mr Frazer the Dieri tribe had enjoyed a German Lutheran mission station (since 1866) for forty-four years up to 1910. About 150 Dieri were alive in 1909 (*Totemism*, iii. 344). Nevertheless the Dieri myths published by Mr Siebert in the decadence of the tribe, and when the remnant was under missionaries, show no "alien sediment." Nor do the traditions of Mr Strehlow's Aranda. Their traditions are closely akin, now to those of the Arunta, now to those of the northern tribes, now to those of the Euahlayi of Mrs Langloh Parker (*The Euahlayi Tribe*) in New South Wales, and once more to those of Mr Howitt's south-eastern tribes. There is no trace of Christian influence in the Aranda and Loritja matter, no vestige of "alien" (that is, of European) "sediment," but the account of Atnatu among the Kaitish reported on by Messrs Spencer and Gillen reads like a savage version of Milton's "Fall of the Angels" in *Paradise Lost*. For these reasons we do not reject the information of Mr Strehlow, who is master of several tribal languages, and, of course, does not encourage wicked native rites by providing supplies of flour, tobacco, &c., during the performances, as Mr Howitt and others say that they found it necessary to do. Sceptical colonists have been heard to aver that natives will go on performing rites as long as white men will provide supplies.

[1] *Native Tribes of Central Australia*, p. 123.

in what the Arunta call "the right" divisions; Arunta, that is, were so arrayed that no totem existed in more than one division. Obliged, as now, to marry out of their own exogamous division (one of four sub-classes among the Arunta) into one of the four sub-classes of the opposite side, no man could then find in it a woman of his own totem to marry. But when Arunta ceased to be hereditary, and came to be acquired, as now, by the local accident of the totem spirits—all, in each case, of one totem name, which haunt the supposed place of a child's conception—some totems inevitably would often get out of their original sub-class into another, and thus the same totems are in several divisions. But granting that a man of division A may legally marry a woman of division B, he is not *now* prevented from doing so because his totem (say Wild Cat) is also hers. His or hers has strayed, by accident of supposed place of conception, out of its "right" into its "wrong" division. The words "right" and "wrong" as here used by the Arunta make it certain that they still perceive the distinction, and that, before the Arunta evolved the spiritual view of conception, they had, like other people, their totems in each case confined to a single main exogamous division of their tribe, and therefore no persons could then marry into their own totems.

But when the theory of spiritual conception arose, and was combined, in the Arunta set of tribes alone (it is common enough elsewhere in northern and western Australia), with the *churinga* doctrine, which gave totems by accident, these two factors, as Messrs Spencer and Gillen say, became the causes—"lie at the root"—of the present Arunta system by which persons may marry others of "the right" division, but of "the wrong" totem. That system is strictly confined to the group of tribes (Ilpirra, Loritja, Unmaterja, Kaitish, Arunta) which constitute "the Arunta nation." Elsewhere the belief in spiritual conception widely prevails, but *not* the belief in the connexion of spirits of individuals with the stone *churinga* of individuals. Consequently the Arunta system of marriage within the totem exists nowhere, and the non-exogamous non-hereditary totem exists nowhere, except in the Arunta region. Everywhere else hereditary totems are exogamous.[1]

Thus the practice of acquiring the totem by local accident is absolutely confined to five tribes where the *churinga* doctrine coexists with it. That the *churinga* belief, coexistent with the spiritual theory of conception, is of relatively recent origin is a demonstrable fact. Had it always been present among the Arunta the inevitable result, in the course of ages, would be the scattering of the totems almost equally, as chance would scatter them among the eight exogamous divisions.

This can be tested by experiment. Take eight men, to represent the eight exogamous divisions, and set them apart in two groups of four. Take four packs of cards, 208 cards, to represent the Arunta totems, which are over 200 in number. Deal the cards round in the usual way to each of the eight men; each will receive 26 cards. It will not be found that group A has "the great majority" of spades and clubs, while group B has "the great majority" of diamonds and hearts, and neither group will have "the great majority" of court cards. Accident does not work in that way. But while accident alone *now* determines the totem to which an Arunta shall belong, nevertheless "in the Arunta, as a general rule, the great majority of the members of any one totemic group belong to one moiety of the tribe; but this is by no means universal . . ."—that is, of the totems the great majority in each case, as a rule, belongs to one or the other set of four exogamous sub-classes.[2]

The inference is obvious. While chance has now placed only the small minority of each totem in all or several of the eight exogamous divisions, the great majority of totems is in *one or another* of the divisions. This great majority cannot come by chance, as Arunta totems *now* come; consequently it is but lately that chance has determined the totem of each individual. Had chance from the first been the determining cause, each totem would not be fairly equally present in each of the two sets of four exogamous divisions. But determination by accident has only existed long enough to affect "as a general rule" a small minority of cases. "The great majority" of totems remain in what is recognized as "the right," the original divisions, as elsewhere universally. Arunta myth sometimes supports, sometimes contradicts, the belief that the totems were originally limited, in each case, to one or other division only, and, being self-contradictory, has no historic value.

A further proof of our point is that the northern neighbours of the Arunta, the Kaitish, have only partially accepted Arunta ideas, religious and social. Unlike the Arunta they have a creative being, Atnatu, from whom half of the population descend; the other half were evolved out of totemic forms.[3] In the same way the Kaitish totems "are more strictly divided between the two moieties" (main exogamous divisions) "of the tribe."[4] Consequently a man *may* marry a woman of his own totem if she be in the right exogamous division. "She is not actually forbidden to him, as a wife becomes of this identity and totem, as she would be in the Warramunga neighbouring tribe . . ." "It is a very rare thing for a man to marry a woman of the same totem as himself,"[5] naturally, for the old rule holds, in sentiment, and a totem is still very rarely in the wrong division. The Arunta system of accidental determination of the totem has as yet scarcely produced among the Kaitish any of its natural and important effects.

This view of the case seems logical: Arunta non-exogamous non-hereditary totemism is the result, as Messrs Spencer and Gillen show, of the theory of spiritual conception and the theory of the relation of the spirit part of each individual to his *churinga*. These two beliefs have already caused a minority of Arunta totems to get out of the original and into the wrong exogamous Arunta divisions. The process is not of old standing; if it were, *all* totems would now be fairly distributed among the divisions by the laws of chance. In the Kaitish tribe, on the other hand, the processes must be of very recent operation, for they have only begun to produce their necessary effects. The totemism of the Arunta is thus the reverse of "primitive," and has but slightly affected the Kaitish.

Precisely the opposite view of the facts is taken by Mr Frazer in his erudite and exhaustive work *Totemism.* In the Kaitish, he writes, "we may detect the first stage in the transition from promiscuous marriage and fortuitous descent of the totem to strict exogamy of the totem clans and strict heredity of the totems in the paternal line."[6] By "promiscuous marriage," marriage within or without the totem, at pleasure, is obviously intended, for the Arunta do not marry "promiscuously"—do not marry their nearest kin.

How, on Mr Frazer's theory, was the transition from the condition of the Arunta to that of the Kaitish made? If the Kaitish were once in the actual Arunta stage of totemism, how did their totems come now to be much more strictly divided between the two moieties, though "the division is not so *absolute* as amongst the Urabunna in the south and the tribes farther north . . ."? How did this occur? The Kaitish have not made totems hereditary by law; they are acquired by local accident. They have not made a rule that all totems should, as among the more northern neighbours of the Arunta, be regimented so that no totem occurs in more than one division: to this rule there are exceptions. A man "is not actually forbidden" to marry a woman of his own totem provided she be of "the right division," but it is clear that he "does not usually do so." This we can explain as the result of a survival in manners of the old absolute universal prohibition.

Meanwhile our view of the facts makes all the phenomena seem natural and intelligible in accordance with the statement of the observers, Messrs Spencer and Gillen, that the cause of the unique non-hereditary non-exogamous totems of the Arunta is the combination of the *churinga* spiritual belief with the belief in spiritual conception. This cause, though now present among

[1] *N.T.C.A.* p. 257; cf. Frazer, *Totemism*, i. 200–201.

[6] *Totemism*, i. 244.

the Kaitish, has, so far, operated but faintly. We have been explicit on these points because on them the whole problem of the original form of totemism hinges. In our view, for the reasons stated, the Arunta system of non-exogamous non-hereditary totemism is a peculiarity of comparatively recent institution. But Mr Frazer, and the chief observer of the phenomena, Mr Spencer, consider the Arunta system, non-exogamous and non-hereditary, to be the most archaic form of totemism extant.

As to non-hereditary, we find another report of the facts in *Die Aranda und Loritja Stämme*, by the Rev. Mr Strehlow, who has a colloquial and philological knowledge of the language of these tribes. As he reports, among other things, that the Aranda (Arunta) in his district *inherit* their mother's totems, in addition to their "local totems," they appear to retain an archaic feature from which their local totem system and marriage rules are a departure.[1]

The hereditary maternal totem is, in Mr Strehlow's region, the protective being (*altjira*) of each Arunta individual.

Are the Arunta "Primitive" or not?—In the whole totemic controversy the question as to whether the non-exogamous non-hereditary totemism of the Arunta or the hereditary and exogamous totemism of the rest of Australia and of totemic mankind, be the earlier, is crucial.

That Arunta totemism is a freak or "sport," it is argued, is made probable first by the fact that the Arunta inherit all things hereditable in the male line, whereas inheritance in the female descent is earlier. (To this question we return; see below, *Male and Female Lines of Descent.*) M. Van Gennep argues that tribes in contact, one set having female, the other male, descent, "like the Arunta have combined the systems."[2] But several northern tribes with male descent of the totem which are *not* in contact with tribes of female descent show much stronger traces of the "combination" than the Arunta, who intermarry freely with a tribe of female descent, the Urabunna; while the Urabunna, though intermarrying with the Arunta who inherit property and tribal office in the male line, show no traces of "combination." Thus the effects occur where the alleged causes are not present; and the alleged causes, in the case of the Urabunna and Arunta, do not produce the effects.

Next the Arunta have no names for their main exogamous divisions, these names being a very archaic feature which in many tribes with sub-classes tend to disappear. In absence of phratry names the Arunta are remote from the primitive. M. Van Gennep replies that perhaps the Arunta have not yet made the names, or have not yet borrowed them. This is also the view of Mr Frazer. As he says, the Southern Arunta lived under the rule of eight classes, but of these four were anonymous, till the names for them were borrowed from the north. The people can thus have anonymous exogamous divisions; the two main divisions, or phratries, of the Arunta may, therefore, from the first, have been anonymous.

To this the reply is that people borrow, if they can, what they need. The Arunta found names for their four hitherto anonymous classes to be convenient, so they borrowed them. But when once class-names did, as they do, all that is necessary, the Arunta had no longer any use for the names of the two primary main divisions: these were forgotten; there is nothing to be got by borrowing that; while four Arunta "sub-classes" are gaining their names, the "classes" (phratries or main divisions) have lost them. It is perfectly logical to hold that while things useful, but hitherto anonymous, are gaining names, other things, now totally useless, are losing their names. One process is as natural as the other. In all Australia tribes with two main divisions and no sub-classes, the names of the two main divisions are found, because the names are useful. In several tribes with named sub-classes, which now do the work previously thrown on the main divisions, the names of the main divisions are unknown: the main divisions being now useless, and superseded by the sub-classes. The absence of names of the two main divisions in the Arunta is merely a result, often found, of the rise of the sub-classes, which, as Mr Frazer declares, are not primitive, but the result of successive later legislative acts of division.[3]

Manifestly on this point the Arunta are at the farthest point from the earliest organization: their loss of phratry names is the consequence of this great advance from the "primitive."

All Arunta society rests on a theory of reincarnated spirits, a theory minutely elaborated. M Van Gennep asks "why should this belief not be primitive?" Surely neither the belief in spirits, nor the elaborate working out of the belief connecting spirits with manufactured stone amulets, can have been primitive. Nobody will say that peculiar stone amulets and the Arunta belief about spirits associated with them are primitive. To this M Van Gennep makes no reply.[4]

The Arunta belief that children are spirit-children (*ratapa*) incarnated is very common in the other central and northern tribes, and, according to Mrs Bates, in Western Australia; Dr Roth reports the same for parts of Queensland. It is alleged by Messrs Spencer and Gillen that the tribes holding this belief deny any connexion between sexual unions and procreation. Mr Strehlow, on the other hand, says that in his region the older Arunta men understand the part of the male in procreation; and that even the children of the Loritja and Arunta understand, in the case of animals.[5] (Here corroboration is desirable and European influence may be asserted.) Dr Roth says that the Tully River blacks of Queensland admit procreation for all other animals, which have no Koi or soul, but not for men, who have souls. (Their theory of human birth, therefore, merely aims primarily at accounting for the spiritual part of man.)[6]

According to Mrs Bates, some tribes in the north of South Australia, tribes with the same "class" names as the Arunta, hold that to have children a man must possess two spirits (*ranee*). If he has but one, he remains childless. If he has two, he can dream of an animal, or other object, which then passes into his wife, and is born as a child, the animal thus becoming the child's totem. This belief does not appear to apply to reproduction in the lower animals. It is a spiritual theory of the begetting of a soul incarnated. If a man has but one spirit, he cannot give one to a child, therefore he is childless.

It is clear that this, and all other systems in which reproduction is explained in spiritual terms, can only arise among peoples whose whole mode of thinking is intensely "animistic." It is also plain that all such myths answer two questions—(1) How does a being of flesh and spirit acquire its spiritual part?—(2) How is it that every human being is in mystical *rapport* with an animal, plant, or other object, the totem? Manifestly the second question could not arise and need answer *before mankind were actually totemists.* It may be added that in the south of Western Australia the name for the mythical "Father of All" (a being not there worshipped, though images of him are made and receive some cult at certain licentious festivals) and the name for "father-stock" is *maman*, which Mrs Bates finds to be the native term for *membrum virile.* All this appears to be proof of understanding of the male part in reproduction, though that understanding is now obscured by speculation about spirits.

The question arises then, is the ignorance of procreation, where that ignorance exists, "primitive," and is the Arunta totemism also "primitive," being conditioned, as we are told it is, by the unique belief in some *churinga*? Or is the ignorance due to attempts of native thinkers to account for the spirit in man as a pre-existing entity that has been from the beginning? The former view is that of Messrs Spencer and Gillen, and Mr Frazer. For the latter see Lang, *Anthropological Essays presented to E. B. Tylor*, pp. 210–218. We can hardly call people primitive because they have struggled with the problem "how has material man an indwelling spirit?"

Theories of the Origin of Totemic Exogamy.—Since the word "exogamy" as a name for the marriage systems connected (as a rule) with totemism was used by J. F. McLennan in his

Primitive Marriage (1866), theories of the origin of exogamy have been rife and multifarious. All, without exception, are purely conjectural. One set of disputants hold that man (whatever his original condition may have been) was, when he first passed an Act of Exogamy, a member of a *tribe*. Howitt's term for this tribe was "the undivided commune." It had, according to him, its inspired medicine-man, believed to be in communication with some superior being. It had its probouleutic council of elders or "headmen" and its general assembly. Such was man's political condition.[1] It is not distinguishable from that of many modern Australian tribes. Other tribes, said by some to be the most primitive, the Arunta and their neighbours, pay no attention to the dictates of a superior being, and the Arunta of Spencer and Gillen seem to know no such entity, though as Atnatu, Tukura, Altjira, and "the Great Ulthaana of the heavens," he exists in a dwindled form among the Kaitish, Loritja and outlying portions of the Arunta tribe. In religion Howitt's early men were already in advance of Mr Spencer's Arunta. Socially, man, at this date, according to Howitt, at first left the relations of the sexes wholly unregulated; the nearest kinsfolk by blood coupled at will, though perfectly aware that they were, at least on the maternal side, actual brothers and sisters, parents and children.

Upholders of the first theory, that man lived promiscuously in a tribal state with legislative assemblies and then suddenly reformed promiscuity away, must necessarily differ in their opinion as to the origins of totems and exogamy from the friends of the second theory, who believe that man never was "promiscuous," and given to sexual union with near kin. Why man, on the first theory—familiar as he was with unions of the nearest kin—suddenly abolished them is explained in four or five different ways. Perhaps the most notable view is Mr Frazer's; he easily confutes, in thirty-five pages, the other hypotheses.[2] Man saw, or thought he saw, injurious consequences to the wedded near-related couples, and therefore he prohibited, first, unions between mothers and sons, and brothers and sisters.[3] But, in his fourth volume, Mr Frazer sees conclusive objections to this view[4] and prefers another. Some peoples, far above the estate of savagery, believe that human incest blights and sterilizes the crops, women and animals. "If any such belief were entertained by the founders of exogamy, they would clearly have been perfectly sufficient motives for instituting the system, for they would perfectly explain the horror with which incest has been regarded and the extreme severity with which it has been punished."[5] That is to say, people had a horror and hatred of incest because they supposed that it blighted the crops and other things. Mr Frazer had previously written (iv. 108) "It is important to bear steadily in mind that the dislike of certain marriages must always have existed in the minds of the people, or at least of their leaders, before that dislike, so to say, received legal sanction by being embodied in an exogamous rule."

Again (iv. 112) "There had, for some reason unknown to us, been long growing up a strong aversion to consanguineous unions"—before any legislative bar was raised against them. This is insisted on. The prohibition "must have answered to certain general sentiments of what was right and proper" (iv. 121). But here the theorist has to explain the origin of the strong aversion, the general sentiment that unions of near kin are wrong and improper. But Mr Frazer does not seem to explain the point that most needs explanation. That "strong aversion," that "general sentiment," cannot have arisen from a growing belief that unions of close kin spoiled the crops or the natural resources of the country. That superstition could only arise as a consequence of the horror and aversion with which "incest" was regarded. Now no idea corresponding to "incest" could arise before unions of near kin were deemed abominable. When once such unions were thought hateful to gods and men, and an upsetting of the cosmic balance, then, but not till then, they might be regarded as injurious to the crops. All such beliefs are sanctions of ideas already in strong force. The idea that such or such a thing is wrong begets the prohibition, followed by the sanction—the belief that the practice of the thing is injurious in a supernormal way: where that belief exists. We do not know it in Australia, for example.

A belief that close sexual unions were maleficent cosmic influences could not possibly arise previous to, and could not then cause, "the dislike of certain marriages"; "the strong aversion to consanguineous unions"—which existed already. This latest guess of Mr Frazer at the origin of the idea of "incest"—of the abomination of certain unions—is untenable. What he has to explain is the origin of the dislike, the aversion, the horror. Once that has arisen, as he himself observes, the prohibition follows, and then comes the supernormal sanction. Thus no theory of exogamous rules as the result of legislation to prevent the unions of persons closely akin, can produce, or has produced, any reason for the aversion to such unions arising among people to whom, on the theory, they were familiar. Mr Frazer has confuted the guesses of MacLennan, Morgan, Durkheim and others; but his own idea is untenable.

The Supposed Method of Reform.—On Mr Frazer's theory the reformers first placed half of the mothers of the tribe, with their children, in division A; and the rest of the mothers, with their children, in division B. The members of each division (phratry) must marry out of it into the other, and thus no man could marry his sister or mother. (The father could marry his daughter, but in tribes with no exogamous explicit rule against the union, he never does.) Later the two divisions were bisected each into a couple of pairs (classes) preventing marriage between father and daughter; and another resegmentation prohibited the unions of more distant relations. These systems, from the simplest division into two phratries, to the more complex with two "sub-classes" in each phratry, and the most elaborate of all with four sub-classes in each phratry, exist in various tribes. Environment and climate have nothing to do with the matter. The Urabunna and the Arunta live in the same climate and environment, and intermarry. The Urabunna have the most primitive, the Arunta have the most advanced of these organizations. While the rules are intended to prevent consanguineous marriages, the names of the "sub-classes" (when translatable, the names of animals) cannot perhaps be explained. They have a totemic appearance.

Totems in Relation to Exogamy.—So far, in this theory nothing has been said of totems, though it is an all but universal rule that people of the same totem may not intermarry, even if the lovers belong to tribes separated by the breadth of the continent. In fact, according to the hypothesis which has been set forth, totems, though now exogamous, played no *original* part in the evolution of exogamy. They came in by accident, not by design, and dropped into their place in a system carefully devised.

Originally, on this theory, a totem came to a child, not as is usual now, by inheritance, but by pure accident; the mother supposing that any object which caught her attention at the moment when she first felt the life of her child, or any article of food which she had recently eaten, became incarnate in her, so that the emu (say) which she saw, or had eaten of, was her child. He or she was an Emu man or woman, by totem was an Emu.

Certain localities, later, were somehow associated each with one given object—cat, kangaroo, grub, or anything else, and now "local totems" (if the phrase may be used) took the place of "conceptional totems," as among the Arunta. The child inevitably was of the *local* totem and its supposed place of conception.

Finally all tribes except the Arunta "nation" made the totem hereditary, either from mother or father; and as the mother or father, an Emu, was in division A, so was the child, and he or she must marry out of that division into the other, B.[6]

The objections taken to this theory are now to be stated:

[6] Frazer, *Totemism*, i. 157–167.

(i.) The theory can by no possibility apply to tribes with three or more main exogamous divisions or phratries, such as we find in North America. In a three-phratry tribe we are reduced to suppose that there were three sexes, or resort to some other solution not perhaps compatible with the theory. (ii.) We have no evidence that any totemic people, except the Navajoes, think the closest sexual unions injurious to the parties or their offspring. The theory is thus merely extracted from the facts—certain unions are forbidden, therefore they *must* have been deemed injurious. Now, even if they were generally thought injurious, the belief would be a mere inference from the fact that they were forbidden. (iii.) The supposed original legislative exogamous division produced a very different effect than that said to be aimed at, namely, the prohibition of marriage between brothers and sisters. It forbade to every man marriage with half the women of his tribe, most of whom were not, even in the wide native use of the term, his "tribal" sisters, that is, women in a man's phratry of the same status as his own sisters. Such relationships, of course, could not exist before they were created by the supposed Act of Division. It would have been easy to prohibit marriages of brothers with sisters directly, just as, though no exogamous rule forbids, the father, in tribes of female descent, is *directly* forbidden to marry his daughters. The natives can take a simple instead of a bewildering path. To this natural objection Mr Frazer replies:[1] "If we assume, as we have every right to do, that the founders of exogamy in Australia recognized the classificatory system of relationship, and the classificatory system of relationship only, we shall at once perceive that what they intended to prevent was not merely the marriage of a man with his sister, his mother, or his daughter in the physical sense in which we use these terms; their aim was to prevent his marriage with his sister, his mother and his daughter in the classificatory sense of these terms; that is, they intended to place bars to marriage not between individuals merely but between the whole groups of persons who designated their group, not their individual relationships, their social, not their consanguineous ties, by the names of father and mother, brother and sister, son and daughter. And in this intention the founders of exogamy succeeded perfectly." Mr Frazer's theory of the origin of exogamy appears now to waver. It was[2] that the primal bisection of the tribe was "deliberately devised and adopted as a means of preventing the marriage, at first, of brother with sisters. . . ." Here was the place to say, if it was then intended to say, that the Australians "recognized the classificatory system of relationships only." As a matter of fact they recognize both the consanguine and the classificatory systems. It is not the case that "the savage Australian, it may be said with truth, has no idea of relationships as we understand them, and does not discriminate between his actual father and mother and the men and women who belong to the group, each member of which might have lawfully been either his father or his mother, as the case may be."

This statement is made inadvertently and unfortunately by Messrs Spencer and Gillen,[3] but it is contradicted by their own observations. An Arunta can tell you, if asked, which of all the men whom he calls "father" is his very own father.[4] The Dieri have terms for "great" (actual) and "little" (tribal) father, and so for other relationships. In Arunta orgies a woman's "tribal" "fathers" and "brothers" and "sons" are admitted to her embraces; her actual father and brothers and sons are excluded.[5] Thus, if the prohibition be based on aversion to unions of persons closely akin by blood, as the actual father is excluded, the actual father, among the Arunta, is, or has been, amongst that people, regarded as near of blood to his daughters. The Arunta are ignorant, we are told, of the part of the male in procreation. Be it so, but there has been a time when they were not ignorant, and when the father was recognized as of the nearest kin by blood to his daughters. If not, and if the prohibition is based on hatred of unions of close kin, why is the father excluded? Nothing, in short, can be more certain than that Australian tribes distinguish between "social" or "tribal" relations on the one hand, and close consanguine relations on the other. Among the Arunta office is inherited by a man from his mother's husband, his father *quem nuptiae demonstrant*; not from any "tribal" father.[6]

Mr Frazer[7] apparently meant in his earlier statement that brothers and sisters consanguine, and these only, were to be excluded from intermarriage, because he went on to say that science cannot decide as to whether the closest interbreeding is injurious to the offspring of healthy parents, however near in blood; and that very low savages could not discover what is hidden from modern science. He had therefore marriages of consanguine brothers and sisters present to his mind: "the closest interbreeding." Brothers and sisters were finally forbidden, on this theory, to intermarry, not because of any dread of injury to the offspring. "The only alternative open to us seems to be to infer that these unions were forbidden because they were believed to be injurious to the persons engaged in them, even when they were both in perfect health."[8] These "incestuous unions" are between brothers and sisters, mothers and sons. Here brothers and sisters consanguine, children of the same mother in each case, certainly appear to be intended. Who else, indeed, *can* be intended? But presently[9] we are to assume that the Australians, before they made the first exogamous division of the tribe "recognized the classificatory system of relationship, and the classificatory system only." They meant, *now*, to bar marriage between "whole groups of persons," related by "social, not consanguineous ties." But this seems to be physically impossible. These "whole groups" never existed, and never could exist, as far as we can see, till they were called into being by the legislative division of the tribe into two exogamous phratries—which had not yet been made. How could a man call a whole group of women "nupa," as at present (the word being applied to his wife and to all women of the opposite phratry to his whom he might legally marry) before the new law had constituted such a group? In what sense, again, were all women of a certain status called my "sisters" (like my actual sisters) before the new law made a new group of them—in regard to marriage as sacred as my own sisters now were to me? It cannot be said that *all* women of my status were called, collectively, my "sisters" before the new division of the tribe and new rule arose, because previously, all women of my status in the tribe have been my "sisters." Who else could be collectively my "sisters"? If to marry a "sister" were reckoned dangerous to her and to me, I must have been forbidden to marry all the women of my status in the tribe. How could a law which merely halved the number of my "sisters" remove the unknown danger from half of them? If any women except my actual sisters were, before the new rule, reckoned as *socially* my sisters, all women in the tribe of a certain status must have been so reckoned. If all dangerous, I must marry none of them. But by the new rule, I may marry half of them! Why have they ceased to be dangerous?

If the theory be that originally only brothers and sisters consanguine were thought dangerous to each other in sexual relations, and the superstition was later extended so as to include all "classificatory" brothers and sisters, *who* were in these days (before the exogamous division) classificatory brothers and sisters? How and for what reason were some marriageable girls in the tribe classificatory sisters of a young man while others, equally young and marriageable, were not? The classificatory brothers and sisters must have been all the marriageable youth of both sexes in a generation, in the tribe.

But then if all the youth of a generation, of both sexes, were classificatory brothers and sisters, and if therefore their unions were dangerous to themselves, or to the crops, the danger could not be prevented by dividing them into two sets, and

allowing each set of brothers to marry each set of sisters. The only way to parry the danger was to force all these brothers and sisters to marry out of the local tribe into another local tribe with the same superstition. When that was done, the two local tribes, exogamous and intermarrying, were constituted into the two phratries of one local tribe. But that is not the theory of observers on the spot: their hypothesis is that a promiscuous and communistic local tribe, for no known or conceivable reason, bisected itself into two exogamous and intermarrying "moieties."

On the face of it, it is a fatal objection to the theory that when men dwelt in an undivided commune they recognized no system of relationships but the classificatory, yet were well aware of consanguineous relationships; were determined to prohibit the marriages of people in such relationships; and included in the new prohibition people in no way consanguineous, but merely of classificatory kin. The reformers, by the theory, were perfectly able to distinguish consanguineous kinsfolk, so that they might easily have forbidden them to intermarry; while if *all* the members of the tribe were not in the classificatory degrees of relationship, who were? How were persons in classificatory relationships with each other discriminated from other members of the tribe who were not? They were easily discriminated as soon as the phratries were instituted, but, we think, not before.

Term of Classificatory Relationships.—Here it is necessary to say a few words about "classificatory" terms of relationship. Among many peoples the terms or names which with us denote relationships of consanguinity or affinity, such as Father, Mother, Brother, Sister, Son, Daughter, Husband, Wife, are applied both to the individuals actually consanguineous in these degrees, and also to all the other persons in the speaker's own main exogamous division or phratry who are of the same "age-grade" and social status as the Father, Mother, Brother, Sister, Son, Daughter, Husband, Wife, and so forth. As a man thus calls all the women whom he might legally have married by the same term as he calls his wife, and calls all children of persons of his own "age-grade," class and status by the same name as he calls his own children, many theorists hold this to be a proof of the origin of the nomenclature "in a system of group marriage in which groups of men exercised marital rights over groups of women, and the limitation of one wife to one husband was unknown. Such a system would explain very simply why every man gives the name of wife to a whole group of women, and every woman gives the name of husband to a whole group of men," and so on with all such collective terms of relationship.[1]

Certainly this is a very simple explanation. But if we wished to explain why every Frenchman applies the name which he gives to his "wife" (*femme*) to every "woman" in the world, it would be rather simpler than satisfactory to say that this nomenclature arose when the French people lived in absolute sexual promiscuity. The same reasoning applies to English "wife," German *Weib*, meaning "woman," and so on in many languages. Moreover the explanation, though certainly very simple, is not "the only reasonable and probable explanation." Suppose that early man, as in a hypothesis of Darwin's, lived, not in large local tribes with the present polity of such tribes in Australia, but in "cyclopean families," where the sire controlled his female mates and offspring; and suppose that he, from motives of sexual jealousy, and love of a quiet life, forbade amours between his sons and daughters. Suppose such a society to reach the dimensions of a tribe. The rules that applied to brothers and sisters, mothers and sons, would persist, and the original names for persons in such relationships in the family would be extended, in the tribe, to all persons of the same status: new terms being adopted, or old terms extended, to cover new social relationships created by social laws in a wider society.

Another Theory of the Origin of Totemism and Exogamy.—How this would happen may be seen in studying the other hypothesis of exogamy and totemism.[2] Man was at first, as Darwin supposed, a jealous brute who expelled his sons from the neighbourhood of his women; he thus secured the internal peace of his fire circle; there were no domestic love-feuds. The sons therefore of necessity married out—were exogamous. As man became more human, a son was permitted to abide among his kin, but he had to capture a mate from another herd (exogamy).

The groups received sobriquets from each other, as Emu, Frog, and so forth, a fact illustrated copiously in the practice of modern and English and ancient Hebrew villages.[3]

The rule was now that marriage must be outside of the local group-name. Frog may not marry Frog, or Emu, Emu. The usual savage superstition which places all folk in mystic *rapport* with the object from which their *names* are derived gradually gave a degree of sanctity to Emu, Frog and the rest. They became totems.

Perhaps the captured women in group Emu retained and bequeathed to their children their own group-names; the children were Grubs, Ants, Snakes, &c. in Emu group. Let two such groups, Emu and Kangaroo, tired of fighting for women, make peace with *connubium*, then we have two phratries, exogamous and intermarrying, Emu and Kangaroo, with totem kins within them. (Another hypothesis is necessary if the original rule of all was, as among the Urabunna and other tribes, that each totem kin must marry out of itself into only one other totem kin.[4] But we are not sure of the fact of one totem to one totem marriage.) In short, the existence of the two main exogamous divisions in a tribe is the result of an alliance of two groups, already exogamous and intermarrying, not of a deliberate dissection of a promiscuous horde.[5]

The first objection to this system is that it is not held by observers on the spot, such as Mr Howett and Mr Spencer. But while all the observed facts of these observers are accepted (when they do not contradict their own statements, or are not corrected by fresh observations), theorists are not bound to accept the *hypotheses* of the observers. Every possible respect is paid to facts of observation. Hypotheses as to a stage of society which no man living has observed may be accepted as freely from Darwin as from Howitt, Spencer and L. Morgan.

It is next objected that "the only ground for denying that the elaborate marriage-system" (systems?) "of the Australian aborigines has been devised by them for the purpose which it actually serves, appears to be a preconceived idea that these savages are incapable of thinking out and putting in practice a series of checks on marriage so intricate that many civilized persons lack either the patience or the ability to understand them . . . The truth is that all attempts to trace the origin and growth of human institutions without the intervention of human intelligence and will are radically vicious and foredoomed to failure."[6] But nobody is denying that the whole set of Australian systems of marriage is the result of human emotions, intelligence and will. Nobody is denying that, in course of time, the aborigines have thought out and by successive steps have elaborated their systems. The only questions are, what were the human motives and needs which, in the first instance, set human intelligence and will to work in these directions; and how, in the first instance, did they work? The answers given to these questions are purely and inevitably hypothetical, whether given by observers or by cloistered students.

It is objected, as to the origin of totemism, that too much influence is given to accident, too little to design. The answer is that "accident" plays a great part in all evolution, and that,

[5] This theory, already suggested by the Rev. J. Mathew, and Mr Daniel McLennan, occurred independently to M. Van Gennep, who, in *Mythes et légendes d'Australie*, suppressed his chapter on it, after reading *The Secret of the Totem.* The conclusions were almost identical with those of that work (*Op. cit.* pp. vi. xxxiv.). The details of the evolution, which are many, may be found in *Social Origins and Primal Law*, and revised in *The Secret of the Totem.*

[6] *Totemism*, i. 280, 281.

in the opposed theory, the existence and actual exogamous function of totems is also accidental, arising from ignorance and a peculiar superstition. It is urged that no men would accept a nickname given from without by hostile groups. This is answered by many examples of cases in which tribes, clans, political parties, and, of course, individuals, have accepted sobriquets from without, and even when these were hostile and derisive.[1] It is asked, Why, on this theory, are there but two exogamous divisions in the tribe? The reply is that in America there may be three or more: that in the Urabunna there are as many exogamous divisions (dual) as there are totems, and that these, like the main exogamous divisions, go in pairs, because marriage is between two contracting parties.[2]

It is maintained in this theory that Australian blacks, who are reflective and by no means illogical men, have long ago observed that certain marriages are rigorously barred by their social system, for no obvious reason. Thus a man learns that he must not marry in his own main exogamous division, say Eagle Hawk. He must choose a wife from the opposite division, Crow. She must belong to a certain set of women in Crow, whose tribal status is precisely that, in Crow, of his own sisters, and his "little sisters" (the women of his sister's status) in Eagle Hawk. The reflective tribesman does not know *why* these rules exist. But he perceives that the marriageable women in his own main division bear the same title as his sisters by blood. He therefore comes to the conclusion that they are all what his own sisters manifestly are, "too near flesh," as the natives say in English; and that the purpose of the rule is to bar marriage to him with all the women who bear the name "sisters" that denotes close consanguinity. Presently he thinks that other kinsfolk, actual, or bearing the same collective title as actual kinsfolk of his, are also "too near flesh," and he goes on to bar *them* till he reaches the eight class model; or like some south-eastern tribes, drops the whole cumbrous scheme in favour of one much like our own.

The reflective savage, in short, acts exactly as the Church did when she extended to cousins the pre-existing Greek and Roman prohibitions against the marriages of very near kin; and, again, extended them still further, to exclude persons not consanguineous at all but called by the same title as real consanguines, "father," "mother" and "child" in "gossipred" —godfather, godmother, godchild.

The savage and ecclesiastical processes are parallel and illustrate each other. Probably when a tribe with two main exogamous and intermarrying divisions came into existence in the way which we have indicated, the names used in *families* for father, mother, daughter, son, husband, wife, brother, sister, were simply extended so as to include, in each case, all persons in the tribe who were now of the same status, socially, with the same rights, restrictions and duties, as had been theirs in the fire-circle before the tribe was made a tribe by the union of two exogamous and previously hostile intermarrying local groups; or two sets of such groups. The process is natural; the wide extension now given to old names of relationships saved the trouble of making new names. Thus we have found a reasonable and probable way of accounting for classificatory terminology without adopting the hypothesis that it arose out of "group-marriage" and asking "But how did group-marriage arise?"

There is no accident here, all is deliberate and reflective design, beginning with the purely selfish and peace-loving design of the jealous sire. Meanwhile the totemic prohibition, "no marriage in the same totem name," has been retained and expanded even beyond the tribe, and "however remote the hunting grounds" of two persons, they may not intermarry if their totem name be the same.

Such are the two chief opposed theories of the origins of exogamy, and of the connexions of exogamy with totemism. The second does not enjoy the benefit of notice and criticism in Mr Frazer's *Totemism.*

[1] *The Secret of the Totem*, pp. 128, 134.
[2] For other arguments explaining the duality of the divisions see Van Gennep, *ut supra*, p. xxxiv. and note 1.

Relations of the Social and Religious Aspects of Totemism.—It is a curious fact (if it be accepted as a fact) that the social aspect of totemism—the prohibition to marry a person of the same hereditary totem name—is sometimes strongest where the "religious" prohibition against killing or eating the totem is weakest; while the highest regard is paid to the totem, or to the god which is supposed to inhabit the totem species, where there is no prohibition on marrying within the totem name. Thus in Australia, where (except in the centre, among the Arunta) almost all tribes prohibit marriages within the totem name, it is scarcely possible to find an instance in which irreligious treatment of the totem, killing or eating it, is (as among many other totemic peoples) thought to be automatically or "religiously" punished by illness, death or miscarriage. Religion, in these cases, does not hold that the injured majesty of the totem avenges itself on the malefactor. On the other hand the Samoans, who pay no regard to the sacred animal of each community in the matter of not marrying within his name, believe that he will inflict death if one of his species be eaten—and if no expiatory rite be performed.[3] In Samoa, we saw, the so-called totem is the vehicle of a God; in Australia no such idea is found.

Meanwhile the offence of marrying within the totem name is nowhere automatically punished in any way except among the American Navajos, where, to make certain, the totem kin also inflicts secular penalties;[4] and it is part of the magic of the *Intichiuma* rites for the behoof of the totem that his kin should eat of him sparingly, as on all occasions they may do. In all other quarters, where marriage within the totem kin is forbidden, the penalty of a breach of law has been death or tribal excommunication. The offence is secular. The Euahlayi, who never marry within the totem name, "may and do eat their hereditary totems with no ill effects to themselves."[5] This is very common in South Australia. As a rule, however, in Australia some respect is paid to the actual plant or animal, and some Northern tribes who inherit the paternal totem respect it almost as much as the maternal totem. As they also inherit property in the maternal line, it seems clear that they have passed from female to male descent, as regards the totem, but not as regards inheritance.[6]

Male and Female Descent of the Totem.—It was the almost universal opinion of anthropologists that, in the earliest totemic societies, the totem was inherited from the mother, and that inheritance from the father was a later development. But when the peculiar totemism of the Arunta was discovered, and it was desired to prove that this non-exogamous totemism was the most primitive extant, it was felt to be a difficulty that the Arunta reckon descent of everything hereditable in the male, not the female line. If then, the Arunta were not primitive but advanced, in this matter as well as in their eight sub-classes and ceremonies, how could their totemism be primitive? It would have been easy to reply that a people might be "primitive" in some details though advanced in others—the fact is notorious. But to escape from the dilemma the idea was proposed that neither male nor female descent was more primitive than the other. One tribe might begin with male, one with female descent. Nobody *can* prove that it was not so, but "whereas evidence of the passage from female to male reckoning may be observed, there is virtually none of a change in the opposite direction."[7]

Thus the Worgaia and Northern neighbours of the Arunta, with male descent, have certainly passed through a system of female descent of the totem, and actually inherit property in the female line, while Strehlow's Aranda or Arunta inherit their *mothers'* totems. Moreover Howitt shows us at least one tribe

[6] See for Worgaia and Warramunga reverence of the mother's totem, though they inherit the father's, Spencer and Gillen, *Northern Tribes*, p. 166. That these tribes, though reckoning descent in the paternal line, inherit property in the maternal is certain, see pp. 523, 524.
[7] Thomas, *ut supra*, p. 15.

with female descent, the Dieri, actually in the process of diverging from female to male descent of the totem. "A step further is when a man gives his totem name to his son, who then has those of both father and mother. This has been done even in the Dieri tribe," which appears to mean that it is also done in other tribes.[1]

A difficult case in marriage law is explained by saying that "possibly some man, as is sometimes the case, gave his *Murdu* (totem) to his son, who was then of two *Murdus*, and so could not marry a girl of one of his two totems."[2] We thus see how the change from female to male descent of the totem is "directly led to," as Mr Howitt says,[3] by a man's mere fatherly desire to have his son made a member of his own totem kin. On the other hand, we never read that with male descent of the totem a mother gives hers to son or daughter. All these facts make it hard to doubt (though absolute proof is necessarily impossible) that female everywhere preceded male descent of the totem.

Proof of transition from female to male descent of the totem appears to be positive in some tribes of the south of South Australia. Among them each person inherits his mother's totem, and may not marry a woman of the same. But he also inherits his father's totem, which "takes precedence," and gives its name to the local group. No person, as apparently among the Dieri when a father has "given his totem" to a son, may marry into either his father's or his mother's totem kin (Mrs Bates).

Thus we have a consecutive series of evolutions: (*a*) All inherit the maternal totem only, and must not marry within it. This is the rule in tribes of south-east Australia with female descent. (*b*) Some fathers in this society give their totems to sons, who already inherit their maternal totems. Such sons can marry into neither the paternal nor maternal totems. This was a nascent rule among the Dieri. (*c*) All inherit both the paternal and the maternal totem, and may marry into neither (southern South Australia). (*d*) All inherit the religious regard for the maternal totem, but may marry within it, while they may not marry within the paternal totem (Worgaia and Warramunga of north central Australia). (*e*) The paternal totem alone is religiously regarded, and alone is exogamous (tribes of south-east Australia with male descent). (*f*) The totem is neither hereditary on either side nor exogamous (Spencer's Arunta). (*g*) The maternal totem is hereditary and sacred, but not exogamous (Strehlow's Arunta).

In this scheme we give the degrees by which inheritance of the totem from the mother shades into inheritance of the totem from both parents (Dieri), thence to inheritance of both the maternal and paternal totem while the paternal alone regulates marriage (Worgaia and Warramunga), thence to exclusive inheritance of the paternal, without any regard paid to the maternal totem (some tribes of South Australia), and so on.

Meanwhile we hear of no tribe with paternal descent of the totem in which mothers are giving their own totems also to their children. We cannot expect to find more powerful presumptions in favour of the opinion that tribes having originally only maternal have advanced by degrees to only paternal descent of the totem. Mr Frazer says, "So far as I am aware, there is no evidence that any Australian tribe has exchanged maternal for paternal descent, and until such evidence is forthcoming we are justified in assuming that those tribes which now trace descent from the father formerly traced it from the mother."[4]

We have now provided, however, the evidence for various transitional stages from maternal to paternal descent, but have found no traces of the contrary process, nor more than one way of interpreting the facts. It is admitted by Mr Frazer that in several North American tribes the change from female to male descent has to all appearance been made.[5] Among the Delawares the initial process was much akin to that of the Dieri, who, in a tribe of female descent, "gives" his own totem to his sons. "The Delawares had a practice of sometimes naming a child into its father's clan," and a son thus became a member of his father's clan. This "may very well have served to initiate a change of descent from the female to the male line."[6] Howitt says precisely the same thing about the paternal practice of the Dieri. Thus there is no reason for denying that the change from female to male descent can be made by Australian as readily as by American tribes. We have given evidence for every step in the transition. The opposite opinion arose merely in an attempt to save the primitiveness of the Arunta, some of whom actually still make the maternal totem hereditary.

The change to male descent is socially very important. The totem kin of a man, for example, takes up his blood feud. Where the descent is female a "man may probably have some (totemic) kinsmen in the same group, but equally a considerable number of members of other totem kins." But it is clear that the rule of male descent gives far greater security to the members of a local group; for they are surrounded by kinsmen, local totem groups only occurring where male descent of the totem prevails, or is predominant.[7] The change from female to male descent of the totem, or the adoption of male descent from the first (if it ever occurred) is thus a great social advantage.

The Ways out of Totemism.—While Howitt believed (though later he wavered in his opinion) that female had always preceded male descent of the totem, he also observed that with male descent came in abnormal developments. One of these is that the people of a district with male descent are often known by the name of the region, or of some noted object therein (say wild cherries).[8] They may even regard (or white observers suppose that they regard) some object as their "local totem," yet they marry within that so-called totem. But they take to marrying, not out of the hereditary totem kin, which becomes obsolescent, but out of their own region into some other given locality. Thus in the Kurnai tribe there were no inevitable hereditary totems, but *thundung* were given by the fathers to lads "when about ten years old or at initiation."[9] The animal *thundung* (elder brother) was to protect the boy, or girl (the girl's *thundung* was called *banung*). The names of the creatures, in each case, appear to have been given to their human brothers and sisters; the *thundung* name descended to a man's sons. "The names are perpetuated" (under male descent) "from generation to generation in the same locality."[10]

Thus it appears that when a Kurnai wishes to marry he goes to a locality where he finds girls of *banung* names into which he may lawfully wed. So far he seems, in fact, to practise totemic exogamy; that he has to travel to a particular locality is merely an accident. Though the *thundung* and *banung* names are not inherited at birth by the children, they are given by the father when the child is old enough to need them.[11]

On the whole, we seem to see, in tribes where male descent is of old standing, that the exogamous function of the totem becomes obsolete, but a shadow of him, as *thundung*, retains a sort of "religious" aspect and even an unappreciated influence in marriage law.

In Fiji and Samoa, in Melanesia[12] and British New Guinea, many types of contaminated and variegated survivals of totemism may be studied. In the Torres Islands[13] hero-worship blends with totemic survivals. As in parts of South Africa, where a *tribe*, not a kin, has a sacred animal, as in Fiji, he seems to be the one survivor of many totems, the totem of some dominant local

[7] Except among the Arunta, where, though totems come by change, local groups are usual. See Spencer and Gillen, *Central Tribes*, p. 9. How this occurs we can only guess. See *Folk Lore*, vol. xx., No. 2, pp. 229–231. Here it is conjectured that adults of the totem congregate for the purpose of convenience in performing *Intichiuma*, or magical services for the propagation of the totem as an article of food. For the nature of these rites, common in the central and northern but unknown to the south-eastern tribes, see *Central Tribes*, pp. 167–212, and *Northern Tribes*, pp. 283–320. The Arunta totem aggregates are magical local societies.

[13] Haddon, *Cambridge Expedition*, vol. v.

totem group, before which the other totems have fled, or but dimly appear, or are vehicles of gods, or, in Africa, of ancestral spirits. (These African tribal sacred animals are called Siboko[1].) Some tribes explain that the Siboko originated in an animal sobrique, as ape, crocodile, given from without.[2] Sibokoism, the presence of a sacred animal in a *local tribe*, can hardly be called totemism, though it is probable that the totem of the leading totem kin, among several such totem kins in a tribe, has become dominant, while the others have become obsolete. On the Gold Coast of Africa as long ago as 1819, Bowdich[3] found twelve "families," as he called them, of which most were called by the name of an animal, plant or other object, more or less sacred to them. They might not marry a person of the same kindred name, and there can be little doubt that totemism, with exogamy, had been the rule. But now the rules are broken down, especially in the peoples of the coast. The survivals and other information may be found in the *Journal of the Anthropological Institute* (1906) xxxvi. 178, 188.

There are fainter traces of totemism in the Awemba between Lake Tanganyika and Lake Bangweolo.[4] A somewhat vague account of Bantu totems in British East Africa, by Mr C. W. Hobley, indicates that among exogamous "clans" a certain animal is forbidden as food to each "clan."[5] The largest collection of facts about African totemism, from fresh and original sources, is to be found in Mr Frazer's book. For totemism in British Columbia the writings of Mr Hill Tout may be consulted.[6] The Thlinkit tribes have the institution in what appears to be its earliest known form, with two exogamous phratries and female descent. Among the Salish tribes "personal" totems are much more prominent. Mr Hill Tout, with Professor F. Boas, considers the hereditary exogamous totem to have its origin in the non-exogamous personal totem, which is acquired in a variety of ways. The Salish are not exogamous, and have considerable property and marked distinctions of rank. It does not, therefore, appear probable that their system of badges or crests and personal totems is more primitive than the totemic rules of the less civilized Thlinkits, who follow the form of the south-east Australian tribes.[7]

Other very curious examples of what we take to be aberrant and decadant totemism in New Guinea are given by Mr Seligmann (*Man*, 1908, No. 89), and by Dr Rivers for Fiji (*Man*, 1908, No. 75). Mr Seligmann (*Man*, 1908, No. 100) added to the information and elucidated his previous statements. The "clans" in British south-east New Guinea usually bear geographical names, but some are named after one of the totems in the "clan." "Every individual in the clan has the same linked totems," of which a bird, in each case, and a fish seem to be predominant and may not be eaten. "The clans are exogamous . . . and descent is in the female line." It appears, then, that a man, having several totems, all the totems in his "clan," must marry a woman of another "clan" who has all the totems of her "clan."

Similar multiplicity of totems, each individual having a number of totems, is described in Western Australia (Mrs Bates). In this case the word "totem" seems to be used rather vaguely and the facts require elucidation and verification. In this part of Australia, as in Fiji[8] "pour la naissance . . . l'apparition du totem-animal avait toujours lieu." In Fiji the mother sees the animal, which does not affect conception, and "is merely an omen for the child already conceived." But in Western Australia, as we have seen, the husband dreams of an animal, which is supposed to follow him home, and to be the next child borne by his wife If it is correctly stated that when the husband has dreamed of no animal, while nevertheless his wife has a baby, the husband spears the man whom he suspects of having dreamed of an animal, the marital jealousy takes an unusual form and human life becomes precarious. But probably the husband has some reason for the direction of his suspicions. He never suspects a woman.

"The Banks' Islanders," says Mr Frazer, "have retained the primitive system of conceptional totemism."[9] On the other hand Dr Rivers, who is here our authority, writes "totemism is absent" from "the northern New Hebrides, the Banks' and the Terres groups."[10] In a place where totemism is absent it does not prima facie seem likely that we shall discover "the primitive system of conceptional totemism." The Banks' Islanders have no totemism at all. But they have a certain superstition applying to certain cases, and that superstition resembles Arunta and Loritja beliefs, in which Mr Frazer finds the germs of totemism. The superstition, however, has not produced any kind of totemism in the Banks' group of isles, at least, no totemism is found. "There are," writes Dr Rivers, "beliefs which would seem to furnish the most natural starting-point for totemism, beliefs which Dr Frazer has been led by the Australian evidence" (by part of the Australian evidence, we must say) "to regard as the origin of the institution." Thus, in Banks' Islands we have the starting-point of the institution, without the institution itself, and in many Australian tribes we have the institution—without the facts which are "the most natural starting-point." As far as they go these circumstances look as if "the most natural" were not the actual starting-point. The facts are these: in the Isle of Mota, Banks' group, "many individuals" are under a tabu not to eat, in each case, a certain animal or fruit, or to touch certain trees, because, in each case, "the person is believed to be the animal or fruit in question."

This tabu does not, as in totemism, apply to every individual; but only to those whose mothers, before the birth of the individuals, "find an animal or fruit in their loin-cloths." This, at least, "is usually" the case. No other cases are given. The women, in each case, are informed that their child "will have the qualities of the animal" (or fruit) "or even, it appeared would be himself or herself the animal" (or fruit). A coco-nut or a crocodile, a flying fox or a brush turkey, could not get inside a loin-cloth; the animal and fruits must be of exiguous dimensions. When the animal (or fruit) disappears "it is believed that it is because the animal has at the time of its disappearance entered into the woman. It seemed quite clear that there was no belief in physical impregnation on the part of the animal nor of the entry of a material object in the form of the animal . . , but, so far as I could gather, an animal found in this way was regarded as more or less supernatural, a spirit animal and not one material, from the beginning."

"There was no ignorance of the physical rôle of the human father, and the father played the same part in conception as in cases unaccompanied by an animal appearance." The part played by the animal or fruit is limited to producing a tabu against the child eating it, in each case, and some community of nature with the animal or fruit. Nothing here is hereditary. The superstition resembles some of those of the Arunta, Loritja and Euahlayi. Among the Euahlayi the superstition has no influence; normal totemism prevails; among the Arunta nation it is considered to be, and Dr Rivers seems to think that it is, likely to have been the origin of totemism. In Mota, however, it either did not produce totemism, or it did; and, where the *germ* has survived in certain cases, the institution has disappeared —while the germinal facts have vanished in the great majority of totemic societies. Dr Rivers does not explain how a brush turkey, a sea snake or a flying fox can get into a woman's loin-cloth, yet these animals, also crabs, are among those tabued in this way. Perhaps they have struck the woman's fancy without getting into her loin-cloth.

It is scarcely correct to say that "the Banks' Islanders have retained the primitive system of conceptional totemism." They only present, in certain instances, features like those which are supposed to be the germs of a system of conceptional

totemism. In the case of the Arunta we have demonstrated that hereditary and exogamous totemism of the normal type preceded the actual conceptional method of acquiring, by local accident, "personal totems." If the Banks' Islanders were ever totemists they have ceased to be so, and merely retain, in cases, a superstition analogous to that which, among the Arunta, with the aid of the stone *churinga*, has produced the present unique and abnormal state of affairs totemic.

For totemism in India, see Dalton, *Descriptive Ethnology of Bengal*; for the north of Asia, Strahlenberg's *Description*, &c. (1738); and in all instances Mr Frazer's book.

Myths of Totem Origins.—The myths of savages about the origin of totemism are of no historical value. Not worshipping ancestral spirits, an Australian will not, like an ancestor-worshipping African, explain his totem as an ancestral spirit. But where, as in the north and centre, he has an elaborate philosophy of spirits, there the primal totems exude spirits which are incarnated in women.

In their myths as to the origin of totemism, savages vary as much as the civilized makers of modern hypotheses. Some claim descent from the totem object; others believe that an original race of animals peopled the world; animals human in character, but bestial, vegetable, astral or what not, in form. These became men, while retaining the *rapport* with their original species; or their spirits are continually reincarnated in women and are born again (Arunta of Messrs Spencer and Gillen); or spirits emanating from the primal forms, or from objects in nature, as trees or rocks, connected with them, enter women and are reincarnated (Arunta of Mr Strehlow and some Australian north-western tribes, studied by Mrs Bates). Other Australians believe that the All-Father, Baiame, gave totems and totemic laws to men.[1] There are many other explanatory myths wherever totemism, or vestiges thereof, is found in Australia, Africa, America and Asia.

All the myths of savages, except mere romantic *Märchen*, and most of the myths of peoples who, like the Greeks, later became civilized, are "actiological," that is, are fanciful hypotheses made to account for everything, from the universe, the skies, the sun, the moon, the stars, fire, rites and ceremonies, to the habits and markings of animals. It is granted that almost all of these fables are historically valueless, but an exception has been made, by scholars who believe that society was deliberately reformed by an act bisecting a tribe into two exogamous divisions, for savage myths which hit on the same explanation. We might as well accept the savage myths which hit on other explanations, for example the theory that Sibokoism arose from animal sobriquets. Exceptions are also made for Arunta myths in which the primal ancestors are said to feed habitually if not exclusively on their own totems. But as many totems, fruit, flowers, grubs, and so on are only procurable for no longer than the season of the May-fly or the March-brown, these myths are manifestly fabulous.

Again the Arunta primal ancestors are said to have cohabited habitually with women of their own totem, though without prejudice against women of other totems whom they encountered in their wanderings. These myths are determined by the belief in *oknanikilla*, or spots haunted by spirits all of one totem, which, again, determine the totem of every Arunta. The idea being that the fabled primal ancestors male and female in each wandering group of miracle-workers were always all of one totem, it follows that, if not celibate, which these savages never are, they must have cohabited with women of their own totem, and, by the existing Arunta system, there is no reason why they should not have done so. In no other field of research is historical value attributed to savage legends about the inscrutable past that lies behind existing institutions.

We are thus confronted by an institution of great importance socially where it regulates marriages and the blood-feud, or where it is a bond of social union between kinsmen in the totem or members of a society which does magic for the behoof of its totem (central and north-western Australia), and is of some "religious" and mythical importance when, as in Samoa, the sacred animal is regarded as the vehicle of a god. Of the origin of these beliefs, which have practical effects in the evolution of society and religion, much, we saw, is conjectured, but as we know no race in the act of becoming totemic—as in all peoples which we can study totemism is an old institution, and in most is manifestly decaying or being transmuted—we can only form the guesses of which examples have been given. Others may be found in the works of Herbert Spencer and Lord Avebury, and criticisms of all of them may be read in A. Lang's *Social Origins*.

Whether or not survivals of totems are to be found in the animal worship of ancient Egypt, in the animal attendants of Greek gods, in Greek post-Homeric legends of descent from gods in various bestial disguises, and in certain ancient Irish legends, it is impossible to be certain, especially as so many gods are now explained as spirits of vegetation, to which folk-lore assigns carnal forms of birds and beasts.

Other Things called Totems.—As has been said, the name "totem" is applied by scholars to many things in nature which are not hereditary and exogamous totems. The "local totem" (so called) has been mentioned, also "linked totems."

Personal Totems.—This is the phrase for any animal or other object which has been "given" to a person as a protective familiar, whether by a sorcerer[2] or by a father, or by a congress of spaewives at birth; or whether the person selects it for himself, by the monition of a dream or by caprice. The Euahlayi call the personal totem *Yunbeai*, the true totem they style *Dhe*. They may eat their real but not their personal totems, which answer to the hares and black cats of our witches.

Three or four other examples of tribes in which "personal totems" are "given" to lads at initiation are recorded by Howitt.[3] The custom appears to be less common in Australia than in America and Africa (except in South Australia, where people may have a number of "personal totems"). In one case the "personal totem" came to a man in a dream, as in North America.[4] Here it may be noted that the simplest and apparently the easiest theory of the origin of totemism is merely to suppose that a man, or with female descent a woman, made his or her personal totem hereditary for ever in his or her descendants. But nobody has explained how it happened that while all had evanescent personal totems those of a few individuals only become stereotyped and hereditary for ever.

Sex-Totems.—The so-called "sex totem" is only reported in Australia. Each sex is supposed by some tribes to have its patron animal, usually a bird, and to injure the creature is to injure the sex. When lovers are backward the women occasionally kill the animal patron of the men, which produces horseplay, and "a sort of jolly fight," like sky-larking and flirtation.[5] The old English "jolly kind of fight," between girls as partisans of ivy, and men as of the holly "sex-totem," is a near analogue. It need not be added that "sex-totems" are exogamous, in the nature of things.

Sub-Totems.—This is the name of what are also styled "multiplex totems," that is, numerous objects claimed for their own by totem kins in various Australian regions. The Emu totem kin, among the Euahlayi tribe, claims as its own twenty-three animals and the north-west wind.[6] The whole universe, including mankind, was apparently divided between the totem kins. Therefore the list of sub-totems might be extended indefinitely.[7] These "sub-totems" are a savage effort at universal classification.

Conclusion.—We have now covered the whole field of controversy as to the causes and origins of totemic institutions. Australia, with North America, provides the examples of those institutions which seem to be "nearest to the beginning," and in Australia the phenomena have been most carefully and

elaborately observed among peoples the least sophisticated. In North America most that we know of many great tribes, Iroquois, Hurons, Delawares and others, was collected long ago, and when precision was less esteemed, while the tribes have been much contaminated by our civilization. It has been unavoidably necessary to criticize, at almost every stage, the conclusions and hypotheses of the one monumental collection of facts and theories, Mr Frazer's *Totemism* (1910). Persons who would pursue the subject further may consult the books mentioned in the text, and they will find a copious, perhaps an exhaustive bibliography in the references of Mr Frazer's most erudite volumes, with their minute descriptive account not only of the totemism, but of the environment and general culture of hundreds of human races, in Savagery and in the Lower and Higher Barbarism. (A. L.)

TOTILA (d. 552), king of the Ostrogoths, was chosen king after the death of his uncle Ildibad in 541, his real name being, as is seen from the coinage issued by him, Baduila. The work of his life was the restoration of the Gothic kingdom in Italy and he entered upon the task at the very beginning of his reign, collecting together and inspiring the Goths and winning a victory over the troops of the emperor Justinian, near Faenza. Having gained another victory in 542, this time in the valley of Mugello, he left Tuscany for Naples, captured that city and then received the submission of the provinces of Lucania, Apulia and Calabria. Totila's conquest of Italy was marked not only by celerity but also by mercy, and Gibbon says " none were deceived, either friends or enemies, who depended on his faith or his clemency." Towards the end of 545 the Gothic king took up his station at Tivoli and prepared to starve Rome into surrender, making at the same time elaborate preparations for checking the progress of Belisarius who was advancing to its relief. The Imperial fleet, moving up the Tiber and led by the great general, only just failed to succour the city, which must then, perforce, open its gates to the Goths. It was plundered, although Totila did not carry out his threat to make it a pasture for cattle, and when the Gothic army withdrew into Apulia it was from a scene of desolation. But its walls and other fortifications were soon restored, and Totila again marching against it was defeated by Belisarius, who, however, did not follow up his advantage. Several cities were taken by the Goths, while Belisarius remained inactive and then left Italy, and in 549 Totila advanced a third time against Rome, which he captured through the treachery of some of its defenders. His next exploit was the conquest and plunder of Sicily, after which he subdued Corsica and Sardinia and sent a Gothic fleet against the coasts of Greece. By this time the emperor Justinian was taking energetic measures to check the Goths. The conduct of a new campaign was entrusted to the eunuch Narses; Totila marched against him and was defeated and killed at the battle of Tagina in July 552.

See E. Gibbon, *Decline and Fall*, edited by J. B. Bury (1898), vol. iv; T. Hodgkin, *Italy and her Invaders* (1896), vol. iv. and Kampfner, *Totila, König der Ostgoten* (1889).

TOTNES, GEORGE CAREW, or CAREY, EARL OF (1555-1629), English politician and writer, son of Dr George Carew, dean of Windsor, a member of a well-known Devonshire family, and Anne, daughter of Sir Nicholas Harvey, was born on the 29th of May 1555,[1] and was educated at Broadgates Hall, Oxford, where he took the degree of M.A. in 1588. He distinguished himself on the field on several occasions and filled important military commands in Ireland. In 1584 he was appointed gentleman-pensioner to Queen Elizabeth, whose favour he gained. In 1586 he was knighted in Ireland. Refusing the embassy to France, Sir George Carew was made master of the ordnance in Ireland in 1588, in 1590 Irish privy councillor; and in 1592 lieutenant-general of the ordnance in England, in which capacity he accompanied Essex in the expedition to Cadiz in 1596 and to the Azores in 1597. In 1598 he attended Sir Robert Cecil, the ambassador, to France. He was appointed treasurer at war to Essex in Ireland in March 1599, and on the latter's sudden departure in September of the same year, leaving the island in disorder, Carew was appointed a lord justice, and in 1600 president of Munster, where his vigorous measures enabled the new lord deputy, Lord Mountjoy, to suppress the rebellion. He returned to England in 1603 and was well received by James I., who appointed him vice-chamberlain to the queen the same year, master of the ordnance in 1608, and privy councillor in 1616; and on the accession of Charles I. he became treasurer to Queen Henrietta Maria in 1626. He sat for Hastings in the parliament of 1604, and on the 4th of June 1605 was created Baron Carew of Clopton, being advanced to the earldom of Totnes on the 5th of February 1626. In 1610 he revisited Ireland to report on the state of the country; and in 1618 pleaded in vain for his friend Sir Walter Raleigh. He died on the 27th of March 1629, leaving no issue. He married Joyce, daughter of William Clopton, of Clopton in Warwickshire.

Besides his fame as president of Munster, where his administration forms an important chapter in Irish history, Carew had a considerable reputation as an antiquary. He was the friend of Camden, of Cotton and of Bodley. He made large collections of materials relating to Irish history and pedigrees, which he left to his secretary, Sir Thomas Stafford, reputed on scanty evidence to be his natural son; while some portion has disappeared, 39 volumes after coming into Laud's possession are now at Lambeth, and 4 volumes in the Bodleian Library. A calendar of the former is included in the State Papers series edited by J. S. Brewer and W. Bullen. His correspondence from Munster with Sir Robert Cecil was edited in 1864 by Sir John Maclean, for the Camden Society, and his letters to Sir Thomas Roe (1615-1617) in 1860. Other letters or papers are in the Record Office; among the MSS. at the British Museum and calendared in the *Hist. MSS. Com. Series, Marquess of Salisbury's MSS.* Stafford published after Carew's death *Pacata Hibernia, or the History of the Late Wars in Ireland* (1633), the authorship of which he ascribes in his preface to Carew, but which has been attributed to Stafford himself. This was reprinted in 1810 and re-edited in 1896. *A Fragment of the History of Ireland*, a translation from a French version of an Irish original, and *King Richard II.... in Ireland* from the French, both by Carew, are printed in Walter Harris's *Hibernica* (1757). According to Wood, Carew contributed to the history of the reign of Henry V. in Speed's *Chronicle*. His opinion on the alarm of the Spanish invasion in 1596 has also been printed.

See also the *Life of Sir P. Carew*, ed. by Sir J. Maclean (1857).

TOTNES, a market town and municipal borough in the Totnes parliamentary division of Devonshire, England, on the Dart, 29 m. S.S.W. of Exeter, by the Great Western railway. Pop. (1901), 4035. It stands on the west bank of the river, and is joined by a bridge to the suburb of Bridgetown. It was formerly a walled town, and two of the four gates remain. Many old houses are also preserved, and in High Street their overhanging upper stories, supported on pillars, form a covered way for foot-passengers. The castle, founded by the Breton Juhel, lord of the manor after the Conquest, was already dismantled under Henry VIII.; but its ivy-clad keep and upper walls remain. The grounds form a public garden. Close by are the remains of St Mary's Priory, which comprise a large Perpendicular gatehouse, refectory, precinct wall, abbot's gate and still-house. A grammar school, founded 1554, occupied part of the Priory, but was removed in 1874 to new buildings. The Perpendicular church of St Mary contains a number of interesting tombs and effigies dating from the 15th century onwards, and much excellent carved work. The guildhall is formed from part of the Priory. Vessels of 200 tons can lie at the wharves near the bridge. The industries include brewing, flour milling, and the export of agricultural produce, chiefly corn and cider. Trout and salmon are plentiful in the river. The town is governed by a mayor, 4 aldermen and 12 councillors. Area 1423 acres.

Totnes (*Toteneis*, *Totton*) was a place of considerable importance in Saxon times; it possessed a mint in the reign of Æthelred, and was governed by a portreeve. In the Domesday Survey it appears as a mesne borough under Juhel of Totnes, founder of the castle and priory; it had 95 burgesses within and 15 without the borough, and rendered military service according

[1] According to his own statement, *Archaeologia*, xii. 401. In the introduction, however, to the Calendar of Carew MSS. the date of his birth is given as 1558, and his admission into Broadgates Hall in 1572, aged 15. In the preface to Carew's Letters to Roe it is given as 1557.

to the custom of Exeter. In 1215 a charter from John instituted a gild merchant with freedom from toll throughout the land. A mayor is mentioned in the court roll of 1386–1387; and a charter from Henry VII. in 1505 ordered that the mayor should be elected on St Matthew's day, and should be clerk of the market. The present governing charter was granted by Elizabeth in 1596, and instituted a governing body of a mayor, fourteen masters or councillors, and an indefinite number of burgesses, including a select body called "the Twenty-men." A fresh charter of incorporation from James II. in 1689 made no alterations of importance. The borough was represented in parliament by one member in 1295, and by two members from 1298 until disfranchised by the act of 1867. A market on Saturday existed at least as early as 1255, and in 1608 is described as well stocked with provisions. The charter of Elizabeth granted a three days' fair at the feast of SS Simon and Jude (Oct. 28), and in 1608 fairs were also held on May day and at the feast of St James (July 25). The market day has been transferred to Friday, but the May and October fairs are continued. The town was formerly noted for serges, and in 1641 the inhabitants represented their distress owing to the decline of the woollen trade. The industry is now extinct. During the Civil War General Goring quartered his troops at Totnes, and Fairfax also made it his temporary station.

See *Victoria County History; Devonshire*; *The History of Totnes, its neighbourhood and Berry Pomeroy Castle* (Totnes, 1825); William Cotton, *A Graphic and Historical Sketch of the Antiquities of Totnes* (London, 1858).

TOTONICAPAM, or TOTONICAPAN, the capital of the department of Totonicapam, Guatemala, on the same high plateau as Quezaltenango, the nearest railway station, from which it is 12 m. E.N.E. Pop. (1905) about 28,000. Totonicapam is inhabited mainly by Quiché Indians, employed in the making of cloth, furniture, pottery and wooden musical instruments. There are hot mineral springs in the neighbourhood. In 1838 Totonicapam was declared an independent republic, in which the adjoining departments of Sololá and Quezaltenango were included. This state existed for two years, and was then again merged in the republic of Guatemala. Totonicapam suffered greatly in the earthquake of the 18th of April 1902.

TOTTENHAM, an urban district in the Tottenham parliamentary division of Middlesex, England, forming a north suburb of London, 6½ m. north of London Bridge, adjoining Edmonton on the south. Pop. (1901), 102,541. Its full name, not now in use, was Tottenham High Cross, from the cross near the centre of the township. The origin and significance of this cross are doubtful. The present structure was erected *c.* 1600, and ornamented with stucco in 1809. In the time of Isaak Walton there stood by it a shady arbour to which the angler was wont to resort. Formerly Tottenham was noted for its "greens," in the centre of one of which stood the famous old elm trees called the "Seven Sisters"; these were removed in 1840, but the name is preserved in the Seven Sisters Road. Bruce castle, on the site of the old mansion of the Bruces, but built probably by Sir William Compton in the beginning of the 16th century, was occupied by a boarding-school founded by Mr (afterwards Sir) Rowland Hill in 1827 on the system instituted by him at Hazlewood, Birmingham. It became public property in 1892. The church of All Hallows, Tottenham, was given by David, king of Scotland (*c.*1126), to the canons of the church of Holy Trinity, London. It retains Perpendicular portions, a south porch of brick of the 16th century and numerous ancient monuments and brasses. The grammar school was enlarged and endowed in 1686 by Sarah, dowager duchess of Somerset. The urban district formerly included Wood Green to the west, but this became a separate urban district in 1888 (pop. 34,233).

In the reign of Edward the Confessor the manor of Tottenham was possessed by Earl Waltheof. It was inherited by his daughter Maud, who was married first to Simon de St Liz and afterwards to David, son of Malcolm III., king of Scotland, who was created by Henry I. earl of Huntingdon, and received possession of all the lands formerly held by Earl Waltheof. The manor thus descended to William the Lion, king of Scotland, and was granted by him in 1184 to his brother David, earl of Angus and Galloway, the grant being confirmed in 1199 by King John of England, who created him earl of Huntingdon. He married Maud, heiress of Hugh, earl of Chester, and his son John inherited both earldoms. The son married Helen, daughter of Llewelyn, prince of Wales, by whom he was poisoned in 1237, dying without issue. She retained possession till 1254, when the manor was divided between his coheirs Robert de Brus, John de Baliol and Henry de Hastings, each division forming a distinct manor bearing the name of its owner. In 1429 they were reunited in the possession of John Gedeney, alderman of London.

William Bedwell, the Arabic scholar, was vicar of Tottenham, and published in 1632 a *Briefe Description of the Towne of Tottenham*, in which he printed for the first time the burlesque poem, the *Turnament of Tottenham.*

TOTTENVILLE, a former village of Richmond county, New York, U.S.A., and since 1898 a part of New York City. It is on the southern shore of Staten Island in New York Bay and on Staten Island Sound, about 20 m. S.W. of the south extremity of Manhattan Island, and is the terminus of the Staten Island Rapid Transit railway. Marine engines, terra-cotta and boats are manufactured here, and there are oyster fisheries. The "Billopp House" here (still standing) was the scene of the conference, on the 11th of September 1776, between Lord Howe, representing Lord North, and Benjamin Franklin, John Adams and Edward Rutledge, representing the Continental Congress, with regard to Lord North's offer of conciliation. This house, originally called the "Manor of Bentley," was built by Captain Christopher Billopp (1638–1726), who sailed from England in an armed vessel, the "Bentley," in 1667, and, by circumnavigating Staten Island in 24 hours, made it, under the ruling of the duke of York, a part of New York. From the duke of York he received 1163 acres of land, including the present site of Tottenville. The village was long known as Bentley, but in 1869 was incorporated (under a faulty charter, revised in 1894) as Tottenville, apparently in honour of Gilbert Totten, a soldier in the War of Independence.

TOUCAN, the Brazilian name of a bird,[1] long since adopted into nearly all European languages, and apparently first given currency in England (though not then used as an English word) in 1668[2] by W. Charleton (*Onomasticon*, p. 115); but the bird, with its enormous beak and feather-like tongue, was described by Oviedo in his *Sumario de la historia natural de las Indias*, first published at Toledo in 1527 (ch. 42),[3] and, to quote the translation of part of the passage in F. Willughby's *Ornithology* (p. 129), "there is no bird secures her young ones better from the *Monkeys*, which are very noisom to the young of most Birds. For when she perceives the approach of those Enemies, she so settles her self in her Nest as to put her Bill out at the hole, and gives the *Monkeys* such a welcome therewith, that they presently pack away, and glad they scape so." Indeed, so remarkable a bird must have attracted the notice of the earliest European invaders of America, the more so since its gaudy plumage was used by the natives in the decoration of their persons and weapons. In 1555 P. Belon (*Hist. nat. oyseaux*, p. 184) gave a characteristic figure of its beak, and in 1558 Thevet (*Singularitez de la France antarctique*, pp. 88–90) a long description, together with a woodcut (in some respects inaccurate, but quite unmistakable) of the whole bird, under the name of "Toucan," which he was the first to publish. In 1560 C. Gesner (*Icones avium*, p. 130) gave a far better figure (though

[1] Commonly believed to be so called from its cry; but Skeat (*Proc. Philolog. Society*, May 15, 1885) adduces evidence to prove that the Guarani *Tuca* is from *tĩ*, nose, and *cáng*, bone, *i.e.* nose of bone.

[2] In 1656 the beak of an "Aracari of Brazil," which was a toucan of some sort, was contained in the *Musaeum tradescantianum* (p. 2), but the word toucan does not appear there.

[3] The writer has only been able to consult the reprint of this rare work contained in the *Biblioteca de autores españoles* (xxii. 473-515), published at Madrid in 1852.

still incorrect) from a drawing received from Ferrerius, and suggested that from the size of its beak the bird should be called *Burhynchus* or *Ramphestes*. This figure, with a copy of Thevet's and a detailed description, was repeated in the posthumous edition (1585) of his larger work (pp. 800, 801). By 1579 Ambroise Paré (*Œuvres*, ed. Malgaigne, iii. 783) had dissected a toucan that belonged to Charles IX. of France, and about the same time Léry (*Voyage fait en la terre du Brésil*, ch. xi.), whose chief object seems to have been to confute Thevet, confirmed that writer's account of this bird in most respects. In 1599 Aldrovandus (*Ornithologia*, i. 801–803), always ready to profit by Gesner's information, and generally without acknowledgment, again described and repeated the former figures of the bird; but he corrupted his predecessor's *Ramphestes* into *Ramphastos*, and in this incorrect form the name, which should certainly be *Rhamphestes* or *Rhamphastas*, was subsequently adopted by Linnaeus and has since been recognized by systematists. Into the rest of the early history of the toucan's discovery it is needless to go.[1] Additional particulars were supplied by many succeeding writers, until in 1834 J. Gould completed his *Monograph* of the family[2] (with an anatomical appendix by R. Owen), to which, in 1835, he added some supplementary plates; and in 1854 he finished a second and much improved edition. The most complete compendium on toucans is J. Cassin's "Study of the Ramphastidae," in the *Proceedings* of the Philadelphia Academy for 1867 (pp. 100–124).

By recent systematists 5 genera and from 50 to 60 species of the family are recognized; but the characters of the former have never been satisfactorily defined, much less those of numerous subdivisions which it has pleased some writers to invent. There can be little doubt that the bird first figured and described by the earliest authors above named is the *R. toco* of nearly all ornithologists, and as such is properly regarded as the type of the genus and therefore of the family. It is one of the largest, measuring 2 ft. in length, and has a wide range throughout Guiana and a great part of Brazil. The huge beak, looking like the great claw of a lobster, more than 8 in. long and 3 high at the base, is of a deep orange colour, with a large black oval spot near the tip. The eye, with its double iris of green and yellow, has a broad blue orbit, and is surrounded by a bare space of deep orange skin. The plumage generally is black, but the throat is white, tinged with yellow and commonly edged beneath with red; the upper tail-coverts are white, and the lower scarlet. In other species of the genus, 14 to 17 in number, the bill is mostly particoloured—green, yellow, red, chestnut, blue and black variously combining so as often to form a ready diagnosis; but some of these tints are very fleeting and often leave little or no trace after death. Alternations of the brighter colours are also displayed in the feathers of the throat, breast and tail-coverts, so as to be in like manner characteristic of the species, and in several the bare space round the eye is yellow, green, blue or lilac. The sexes are alike in coloration, the males being largest. The tail is nearly square or moderately rounded. In the genus *Pteroglossus*, the "Aracaris" (pronounced Arassari), the sexes more or less differ in appearance, and the tail is graduated. The species are smaller in size, and nearly all are banded on the belly, which is generally yellow, with black and scarlet, while except in two the throat of the males at least is black. One of the most remarkable and beautiful is *P. beauharnaisi*, by some authors placed in a distinct genus and called *Beauharnaisius ulocomus*. In this the feathers of the top of the head are very singular, looking like glossy curled shavings of black horn or whalebone, the effect being due to the dilatation of the shaft and its coalescence with the consolidated barbs. Some of the feathers of the straw-coloured throat and cheeks partake of the same structure, but in a less degree, while the subterminal part of the *lamina* is of a lustrous pearly-white.[3] The beak is richly coloured, being green and crimson above and lemon below. The upper plumage generally is dark green, but the mantle and rump are crimson, as are a broad abdominal belt, the flanks and many crescentic markings on the otherwise yellow lower parts.[4] The group or genus *Selenodera*, proposed by J. Gould in 1837 (*Icones avium*, pt. 1), contains some 6 or 7 species, having the beak, which is mostly transversely striped, and tail shorter than in *Pteroglossus*. Here the sexes also differ in coloration, the males having the head and breast black, and the females the same parts chestnut; but all have a yellow nuchal crescent (whence the name of the group). The so-called hill-toucans have been separated as another genus, *Andigena*, and consist of some 5 or 6 species chiefly frequenting the slopes of the Andes and reaching an elevation of 10,000 ft., though one, often placed among them, but perhaps belonging rather to *Pteroglossus*, the *A. bailloni*, remarkable for its yellow-orange head, neck and lower parts, inhabits the lowlands of southern Brazil. Another very singular form is *A. laminirostris*, which has affixed on either side of the maxilla, near the base, a quadrangular ivory-like plate, forming a feature unique in this or almost in any family of birds. The group *Aulacorhamphus*, or "groove-bills," with a considerable but rather uncertain number of species, contains the rest of the toucans.

The monstrous serrated bill that so many toucans possess was by G. L. L. Buffon accounted a grave defect of nature, and it must be confessed that no one has given what seems to be a satisfactory explanation of its precise use, though on evolutionary principles none will now doubt its fitness to the bird's requirements. Solid as it looks, its weight is inconsiderable, and the perfect hinge by which the maxilla is articulated adds to its efficiency as an instrument of prehension. W. Swainson (*Classif. Birds*, ii. 138) imagined it merely "to contain an infinity of nerves, disposed like net-work, all of which lead immediately to the nostrils," and add to the olfactory faculty. This notion seems to be borrowed from J. W. H. Trail (*Trans. Linn. Society*, xi. 289), who admittedly had it from Waterton, and stated that it was "an admirable contrivance of nature to increase the delicacy of the organ of smell;" but R. Owen's description showed this view to be groundless, and he attributed the extraordinary development of the toucan's beak to the need of compensating, by the additional power of mastication thus given, for the absence of any of the grinding structures that are so characteristic of the intestinal tract of vegetable-eating birds—its digestive organs possessing a general simplicity of formation. The nostrils are placed so as to be in most forms invisible until sought, being obscured by the frontal feathers or the backward prolongation of the horny sheath of the beak. The wings are somewhat feeble, and the legs have the toes placed in pairs, two before and two behind. The tail is capable of free vertical motion, and controlled by strong muscles, so that, at least in the true toucans, when the bird is preparing to sleep it is reverted and lies almost flat on the back, on which also the huge bill reposes, pointing in the opposite direction.

The toucans are limited to the new world, and by far the greater number inhabit the north of South America, especially Guiana and the valley of the Amazons. Some three species occur in Mexico, and several in Central America. One, *R. vitellinus*, which has its head-quarters on the mainland, is said to be common in Trinidad, but none are found in the Antilles proper. They compose the family Rhamphastidae of Coraciiform birds, and are associated with the woodpeckers (Picidae) and puff-birds and jacamars (Galbulidae); their nearest allies perhaps exist among the Capitonidae, but none of these is believed to have the long feather-like tongue which is so characteristic of the toucans, and is, so far as known, possessed besides only by the Momotidae (see MOTMOT). But of these last there is no reason to deem the toucans close relatives, and according to W. Swainson, who had opportunities of observing both, the alleged resemblance in their habits has no existence. Toucans in confinement feed mainly on fruit, but little seems amiss to them, and they swallow grubs, reptiles and small birds with avidity. They nest in hollow trees, and lay white eggs. (A. N.)

TOUCH (derived through Fr. *toucher* from a common Teutonic and Indo-Germanic root, cf. "tug," "tuck," O. H. Ger. *zucchen*, to twitch or draw), in physiology, a sense of pressure, referred usually to the surface of the body. It is often understood as a sensation of contact as distinguished from pressure, but it is evident that, however gentle be the contact, a certain amount of pressure always exists between the sensitive surface and the body touched. Mere contact in such circumstances is gentle pressure; a greater amount of force causes a feeling of resistance or of pressure referred to the skin; a still greater amount causes a feeling of muscular resistance, as when a weight is supported on the palm of the hand; whilst, finally, the pressure may be so great as to cause a feeling of pain. The force may not be exerted

[1] One point of some interest may, however, be noticed. In 1705 Plot (*N.H. Oxfordshire*, p. 182) recorded a toucan found within two miles of Oxford in 1644, the body of which was given to the repository in the medical school of that university, where, he said, "it is still to be seen." Already in 1700 Leigh in his *Lancashire* (i. 195, Birds, tab. 1, fig. 2) had figured another which had been found dead on the coast of that county about two years before. The bird is easily kept in captivity, and no doubt from early times many were brought alive to Europe. Besides the one dissected by Paré, as above mentioned, Joh. Faber, in his additions to Hernandez's work on the Natural History of Mexico (1651), figures (p. 697) one seen and described by Puteus (Dal Pozzo) at Fontainebleau.

[2] Of this the brothers Sturm in 1841 published at Nuremberg a German version.

[3] This curious peculiarity naturally attracted the notice of the first discoverer of the species, Poeppig, who briefly described it in a letter published in Froriep's *Notizen* (xxxii. 146) for December 1831.

[4] Readers of F. Bates's *Naturalist on the River Amazons* will recollect the account (ii. 344) and illustration there given of his encounter with a flock of this species of toucan. His remarks on the other species with which he met are also excellent.

vertically on the sensory surface, but in the opposite direction, as when a hair on a sensory surface is pulled or twisted. Touch is therefore the sense by which mechanical force is appreciated, and it presents a strong resemblance to hearing, in which the sensation is excited by intermittent pressures on the auditory organ. In addition to feelings of contact or pressure referred to the sensory surface, contact may give rise to a sensation of temperature, according as the thing touched feels hot or cold. These sensations of contact, pressure or temperature are usually referred to the skin or integument covering the body, but they are experienced to a greater or less extent when any serous or mucous surface is touched. The skin being the chief sensory surface of touch, it is there that the sense is most highly developed both as to delicacy in detecting minute pressures and as to the character of the surface touched. Tactile impressions, properly so called, are absent from internal mucous surfaces, as has been proved in men having gastric, intestinal and urinary fistulae. In these cases, touching the mucous surface caused pain, and not a true sensation of touch.

In the article NERVE (*Spinal*) the cutaneous distribution of the organs of touch is dealt with.

The Amphibia and Reptilia do not show any special organs of touch. The lips of tadpoles have tactile papillae. Some snakes have a pair of tentacles on the snout, but the tongue is probably the chief organ of touch in most serpents and lizards. All reptiles possessing climbing powers have the sense of touch highly developed in the feet.

Birds have epithelial papillae on the soles of the toes that are no doubt tactile. These are of great length in the capercailzie (*Tetrax urogallus*), "enabling it to grasp with more security the frosted branches of the Norwegian pine trees" (Owen). Around the root of the bill in many birds there are special tactile organs, assisting the bird to use it as a kind of sensitive probe for the detection in soft ground of the worms, grubs and slugs that constitute its food. Special bodies of this kind have been detected in the beak and tongue of the duck and goose, called the tactile corpuscles of F. S. Merkel, or the corpuscles of Grandry (fig. 1). Similar bodies have been found in the epidermis of man and mammals, in the outer root-sheath of tactile hairs or feelers. They consist of small bodies composed of a capsule enclosing two or more flattened nucleated cells, piled in a row. Each corpuscle is separated from the others by a transparent protoplasmic disk. Nerve fibres terminate either in the cells (Merkel) or in the protoplasmic intercellular matter (Ranvier, Hesse, Izquierdo). Another form of end-organ has been described by Herbst as existing in the mucous membrane of the duck's tongue. These corpuscles of Herbst are like small Pacinian corpuscles with thin and very close lamellae. Developments of integument devoid of feathers, such as the "wattles" of the cock, the "caruncles" of the vulture and turkey, are not tactile in their function.

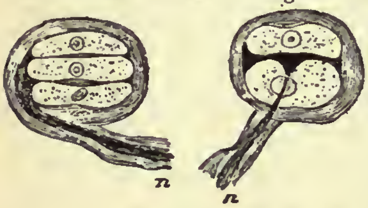

FIG. 1.—Tactile Corpuscles from duck's tongue. *n*, Nerve.

In the great majority of Mammalia the general surface of the skin shows sensitiveness, and this is developed to a high degree on certain parts, such as the lips, the end of a teat and the generative organs. Where touch is highly developed, the skin, more especially the epidermis, is thin and devoid of hair. In the monkeys tactile papillae are found in the skin of the fingers and palms, and in the skin of the prehensile tails of various species (*Ateles*). Such papillae also abound in the naked skin of the nose or snout, as in the shrew, mole, pig, tapir and elephant. In the *Ornithorhynchus* the skin covering the mandibles is tactile (Owen). In many animals certain hairs acquire great size, length and stiffness. These constitute the vibrissae or whiskers. Each large hair grows from a firm capsule sunk deep in the true skin, and the hair bulb is supplied with sensory nerve filaments. In the walrus the capsule is cartilaginous in texture. The marine Carnivora have strong vibrissae which "act as a staff, in a way analogous to that held and applied by the hand of a blind man" (Owen). Each species has hairs of this kind developed on the eyebrows, lips or cheeks, to suit a particular mode of existence, as, for example, the long fine whiskers of the night-prowling felines, and in the aye-aye, a monkey having nocturnal habits.

FIG. 2.—Tactile Corpuscle from the hand.

In the Ungulata the hoofs need no delicacy of touch as regards the discrimination of minute points. Such animals, however, have broad, massive sensations of touch, enabling them to appreciate the firmness of the soil on which they tread, and under the hoof we find highly vascular and sensitive lamellae or papillae, contributing no doubt, not only to the growth of the hoof, but also to its sensitiveness. The Cetacea have numerous sensory papillae in the skin. Bats have the sense of touch strongly developed in the wings and external ears, and in some species in the flaps of skin found near the nose. There is little doubt that many special forms of tactile organs will be found in animals using the nose or feet for burrowing. A peculiar end-organ has been found in the nose of the mole, while there are "end-capsules" in the tongue of the elephant and "nerve rings" in the ears of the mouse.

FIG. 3.—Tactile Corpuscles from clitoris of rabbit. *n*, Nerve.

End-Organs of Touch in Man.—In man three special forms of tactile end-organs have been described, and can be readily demonstrated.

1. *The End-Bulbs of Krause.*—These are oval or rounded bodies, from $\frac{1}{360}$ to $\frac{1}{170}$ of an inch long. Each consists of a delicate capsule, composed of nucleated connective tissue

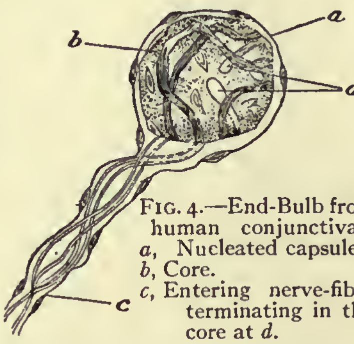

FIG. 4.—End-Bulb from human conjunctiva.

FIG. 5.—End-Bulb from conjunctiva of calf. *n*, Nerve.

enclosing numerous minute cells. On tracing the nerve fibre, it is found that the nerve sheath is continuous with the capsule, whilst the axis cylinder of the nerve divides into branches which lose themselves among the cells. W. Waldeyer and Longworth state that the nerve fibrils terminate in the cells, thus making these bodies similar to the cells described by F. S. Merkel (*ut supra*). (See fig. 4.) These bodies are found in the deeper layers of the conjunctiva, margins of the lips, nasal mucous membrane, epiglottis, fungiform and circumvallate papillae of the tongue, glans penis and clitoris, mucous membrane of the rectum of man, and they have also been found on the under surface of the "toes of the guinea-pig, ear and body of the mouse, and in the wing of the bat" (Landois and Stirling). In the genital organs aggregations of end-bulbs occur, known as the "genital corpuscles of Krause" (fig. 3). In the synovial membrane of the joints of the fingers there are larger end-bulbs, each connected with three four nerve-filaments.

(2) *The Touch Corpuscles of Wagner and Meissner.*—These are oval bodies, about $\frac{1}{300}$ of an inch long by $\frac{1}{500}$ of an inch in breadth. Each consists of a series of layers of connective tissue arranged transversely, and containing in the centre granular matter with nuclei (figs. 2, 3 and 6). One, two or three nerve fibres pass to the lower end of the corpuscle, wind transversely around it, lose the white substance of Schwann, penetrate into the corpuscle, where the axis cylinders, dividing, end in some way unknown. The corpuscles do not contain any soft core, but are apparently built up of irregular septae of connective tissue, in the meshes of which the nerve fibrils end in expansions similar to Merkel's cells. Thin describes simple and compound corpuscles according to the number of nerve fibres entering them. These bodies are found abundantly

in the palm of the hand and sole of the foot, where there may be as many as 21 to every square millimetre (1 mm. = $\frac{1}{25}$ inch). They are not so numerous on the back of the hand or foot, mamma, lips and tip of the tongue, and they are rare in the genital organs.

3. *The Corpuscles of Vater or Pacini.*—These, first described by Vater so long ago as 1741, are small oval bodies, quite visible to the naked eye, from $\frac{1}{16}$ to $\frac{1}{10}$ of an inch long and

$\frac{1}{25}$ to $\frac{1}{20}$ of an inch in breadth, attached to the nerves of the hands and feet. They can be readily demonstrated in the mesentery of the cat (fig. 7). Each corpuscle consists of 40 to 50 lamellae or coats, like the folds of an onion, thinner and closer together on approaching the centre. Each lamella is formed of an elastic material mixed with delicate connective-tissue fibres, and the inner surface of each is lined by a single continuous layer of endothelial cells. A double-contoured nerve fibre passes to each. The white substance of Schwann becomes continuous with the lamellae, whilst the axis cylinder passes into the body, and ends in a small knob or in a plexus. Sometimes a blood-vessel also penetrates the Pacinian body, entering along with the nerve. Such bodies are found in the subcutaneous tissue on the nerves of the fingers and toes, near joints, attached to the nerves of the abdominal plexuses of the sympathetic, on the coccygeal gland, on the dorsum of the penis and clitoris, in the meso-colon, in the course of the intercostal and periosteal nerves, and in the capsules of lymphatic glands.

Physiology of Touch in Man.—Such are the special end-organs of touch. It has also been ascertained that many sensory nerves end in a plexus or network, the ultimate fibrils being connected with the cells of the particular tissue in which they are found. Thus they exist in the cornea of the eye, and at the junctions of tendons with muscles. In the latter situation "flattened end-flakes or plates" and "elongated oval end-bulbs" have also been found. A consideration of these various types of structure show that they facilitate intermittent pressure being made on the nerve endings. They are all, as it were, elastic cushions into which the nerve endings penetrate, so that the slight variation of pressure will be transmitted to the nerve. Probably also they serve to break the force of a sudden shock on the nerve endings.

Sensitiveness and Sense of Locality.—The degree of sensitiveness of the skin is determined by finding the smallest distance at which the two points of a pair of compasses can be felt. This method first followed by Weber, is employed by physicians in the diagnosis

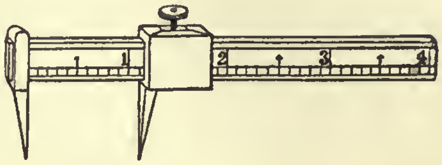

FIG. 8.—Aesthesiometer of Sieveking.

of nervous affections involving the sensitiveness of the skin. The following table shows the sensitiveness in millimetres for an adult.

	Mm.
Tip of tongue	1·1
Third phalanx of finger, volar surface	2–2·3
Red part of the lip	4·5
Second phalanx of finger, volar surface	4–4·5
First phalanx of finger, volar surface	5–5·5
Third phalanx of finger, dorsal surface	6·8
Tip of nose	6·8
Head of metacarpal bone, volar	5–6·8
Ball of thumb	6·5–7
Ball of little finger	5·5–6
Centre of palm	8–9
Dorsum and side of tongue; white of the lips; metacarpal part of the thumb	9
Third phalanx of the great toe, plantar surface	11·3
Second phalanx of the fingers, dorsal surface	11·3
Back	11·3
Eyelid	11·3
Centre of hard palate	13·5
Lower third of the forearm, volar surface	15
In front of the zygoma	15·8
Plantar surface of the great toe	15·8
Inner surface of the lip	20·3
Behind the zygoma	22·6
Forehead	22·6
Occiput	27·1
Back of the hand	31·6
Under the chin	33·8
Vertex	33·8
Knee	36·1
Sacrum (gluteal region)	44·6
Forearm and leg	45·1
Neck	54·1
Back of the fifth dorsal vertebra; lower dorsal and lumbar region	54·1
Middle of the neck	67·7
Upper arm; thigh; centre of the back	67·7

These investigations show not only that the skin is sensitive, but that one is able with great precision to distinguish the part touched. This latter power is usually called the *sense of locality*, and it is influenced by various conditions. The greater the number of sensory nerves in a given area of skin the greater is the degree of accuracy in distinguishing different points. Contrast in this way the tip of the finger and the back of the hand. Sensitiveness increases from the joints towards the extremities, and sensitiveness is great in parts of the body that are actively moved. The sensibility of the limbs is finer in the transverse axis than in the long axis of the limb, to the extent of $\frac{1}{8}$ on the flexor surface of the upper limb and $\frac{1}{4}$ on the extensor surface. It is doubtful if exercise improves sensitiveness, as Francis Galton found that the performances of blind boys were not superior to those of other boys, and he says that "the guidance of the blind depends mainly on the multitude of collateral indications, to which they give much heed, and not their superiority to any one of them." When the skin is moistened with indifferent fluids sensibility is increased. Suslowa made the curious discovery that, if the area between two points distinctly felt be tickled or be stimulated by a weak electric current, the impressions are fused. Stretching the skin, and baths in water containing carbonic acid or common salt, increase the power of localizing tactile impressions. In experimenting with the compasses, it will be found that a smaller distance can be distinguished if one proceeds from greater to smaller distances than in the reverse direction. A smaller distance can also be detected when the points of the compasses are placed one after the other on the skin than when they are placed simultaneously. If the points of the compasses are unequally heated, the sensation of two contacts becomes confused. An anaemic condition, or a state of venous congestion, or the application of cold, or violent stretching of the skin, or the use of such substances as atropine, daturin, morphia, strychnine, alcohol, bromide of potassium, cannabin and hydrate of chloral blunt sensibility. The only active substance said to increase it is caffein.

Absolute sensitiveness, as indicated by a *sense of pressure*, has been determined by various methods. Two different weights are placed on the part, and the smallest difference in weight that can be perceived is noted. Weber placed small weights directly on the skin; Aubert and Kammler loaded small plates; Dohrn made use of a balance, having a blunt point at one end of the beam, resting on the skin, whilst weights were placed on the other end of the beam to equalize the pressure; H. Eulenberg invented an instrument like a spiral spring paper-clip or balance (the baraesthesiometer), having an index showing the pressure in grammes; F. Goltz employed an India-rubber tube filled with water, and this, to ensure a constant surface of contact, bent at one spot over a piece of cork, is touched at that spot by the cutaneous part to be examined, and, by rhythmically exerted pressure, waves analogous to those of the arterial pulse are produced in the tube; and L. Landois invented a mercurial balance, enabling him to make rapid variations in the weight without giving rise to any shock. These methods have given the following general results. (1) The greatest acuteness is on the forehead, temples and back of the hand and forearm, which detect a pressure of 0·002 gramme; fingers detect 0·005 to 0·015 gramme; the chin, abdomen and nose 0·04 to 0·05 gramme. (2) Goltz's method gives the same general results as Weber's experiment with the compasses, with the exception that the tip of the tongue has its sensation of pressure much lower in the scale than its sensation of touch. (3) Eulenberg found the following gradations in the fineness of the pressure sense: the forehead, lips, back of the cheeks, and temples appreciate differences of $\frac{1}{40}$ to $\frac{1}{30}$ (200: 205 to 300: 310 grammes). The back of the last phalanx of the fingers, the forearm, hand, first and second phalanges, the palmar surface of the hand, forearm and upper arm distinguish differences of $\frac{1}{10}$ to $\frac{1}{20}$ (200: 220 to 200: 210 grammes). The front of the leg and thigh is similar to the forearm. Then follow the back of the foot and toes, the sole of the foot, and the back of the leg and thigh. Dohrn placed a weight of 1 gramme on the skin, and then determined the least additional weight that could be detected, with this result: third phalanx of finger 0·499 gramme; back of the foot, 0·5 gramme; second phalanx, 0·771 gramme; first phalanx, 0·82 gramme; leg, 1 gramme; back of hand, 1·156 grammes; palm, 1·108 grammes; patella, 1·5 grammes; forearm, 1·99 grammes; umbilicus, 3·5 grammes; and back, 3·8 grammes. (4) In passing from light to heavier weights, the acuteness increases at once, a maximum is reached, and then with heavy weights the power of distinguishing the differences diminishes. (5) A sensation of pressure after the weights have been removed may be noticed (*after-pressure sensation*), especially if the weight be considerable. (6) Valentine noticed that, if the finger were held against a blunt-toothed wheel, and the wheel were rotated with a certain rapidity, he felt a *smooth* margin. This was experienced when the intervals of time between the contacts of successive teeth were less than from $\frac{1}{480}$ to $\frac{1}{610}$ of a second. The same experiment can be readily made by holding the finger over the holes in one of the outermost circles of a large syren rotating quickly: the sensations of individual holes become fused, so as to give rise to a feeling of touching a slit. (7) Vibrations of strings are detected even when the number is about 1500 per second; above this the sensation of vibration ceases. By attaching bristles to the prongs of tuning-forks and bringing these into contact with the lip or tongue, sensations of a very acute character are experienced, which are most intense when the forks vibrate from 600 to 1500 per second.

Information from Tactile Impressions.—These enable us to come to the following conclusions. (1) We note the existence of something touching the sensory surface. (2) From the intensity of the sensation we determine the weight, tension or intensity of the pressure. This sensation is in the first instance referred to the skin, but after the pressure has reached a certain amount muscular sensations are also experienced—the so-called muscular sense. (3) The locality of the part touched is at once determined, and from this the probable position of the touching body. Like the visual field, to which all retinal impressions are referred, point for point, there is a tactile field, to which all points on the skin surface may be referred. (4) By touching a body at various points, from the difference of pressure and from a comparison of the positions of various points in the tactile field we judge of the configuration of the body. A number of "tactile pictures" are obtained by passing the skin over the touched body, and the shape of the body is further determined by a knowledge of the muscular movements necessary to bring the cutaneous surface into contact with different portions of it. If there is abnormal displacement of position, a false conception may arise as to the shape of the body. Thus, if a small marble or a pea be placed between the index and middle finger so as to touch (with the palm downwards) the outer side of the index finger and the inner side of the middle finger, a sensation of touching *one* round body is experienced; but if the fingers be crossed, so that the marble touches the inner side of the index finger and the outer side of the middle finger, there will be a feeling of *two* round bodies, because in these circumstances there is added to the feelings of contact a feeling of distortion (or of muscular action) such as would take place if the fingers, for purposes of touch, were placed in that abnormal position. Again, as showing that our knowledge of the tactile field is precise, there is the well-known fact that when a piece of skin is transplanted from the forehead to the nose, in the operation for removing a deformity of the nose arising from lupus or other ulcerative disease, the patient feels the new nasal part as if it were his forehead, and he may have the curious sensation of a nasal instead of a frontal headache. (5) From the number of points touched we judge as to the smoothness or roughness of a body. A body having a uniformly level surface, like a billiard ball, is smooth; a body having points irregular in size and number in a given area is rough; and if the points are very close together it gives rise to a sensation, like that of the pile of velvet almost intolerable to some individuals. Again, if the pressure is so uniform as not to be felt, as when the body is immersed in water (paradoxical as this may seem, it is the case that the sensation of contact is felt only at the limit of the fluid), we experience the sensation of being in contact with a fluid. (6) Lastly, it would appear that touch is always the result of variation of pressure. No portion of the body when touching anything can be regarded as absolutely motionless, and the slight oscillations of the sensory surface, and in many cases of the body touched, produce those variations of pressure on which touch depends.

To explain the phenomenon of the tactile field, and more specially the remarkable variations of tactile sensibility above described, various theories have been advanced, but none are satisfactory. (See article "Cutaneous Sensations" by C. S. Sherrington in Schäfer's *Physiology*, ii. 920). Research shows that the sensation of touch may be referred to parts of the skin which do not contain the special end organs associated with this sense, and that filaments in the Malpighian layer (the layer immediately above the papillae of the true skin) may form the anatomical basis of the sense. The skin may be regarded, also, as an extensive surface containing nervous arrangements by which we are brought into relation with the outer world. Accordingly, touch is not the only sensation referred to the skin, but we also refer sensations of temperature (heat and cold), and often those peculiar sensations which we call pain.

Sensations of Temperature.—These depend on thermic irritation of the terminal organs, as proved by the following experiment of E. H. Weber: "If the elbow be dipped into a very cold fluid, the cold is only felt at the immersed part of the body (where the fibres terminate); pain, however, is felt in the terminal organs of the ulnar nerve, namely, in the finger points; this pain, at the same time, deadens the local sensation of cold." If the sensation of cold were due to the irritation of a specific-nerve fibre, the sensation of cold would be referred to the tips of the fingers. When any part of the skin is above its normal mean temperature, warmth is felt; in the opposite case, cold. The normal mean temperature of a given area varies according to the distribution of hot blood in it and to the activity of nutritive changes occurring in it. When the skin is brought into contact with a good conductor of heat there is a sensation of cold. A sensation of heat is experienced when heat is carried to the skin in any way. The following are the chief facts that have been ascertained regarding the temperature sense: (1) E. H. Weber found that, with a skin temperature of from 15·5° C. to 35° C., the tips of the fingers can distinguish a difference of 0·25° C. to 0·2° C. Temperatures just below that of the blood (33°–27° C.) are distinguished by the most sensitive parts, even to 0·05° C. (2) The thermal sense varies in different regions as follows: tip of tongue, eyelids, cheeks, lips, neck, belly. The "perceptible minimum" was found to be, in degrees C.: breast 0·4°; back, 0·9°; back of hand, 0·3°; palm, 0·4°; arm, 0·2°; back of foot, 0·4°; thigh, 0·5°; leg, 0·6° to 0·2°; cheek, 0·4°; temple, 0·3°. (3) If two different temperatures are applied side by side and simultaneously, the impressions often fuse, especially if the areas are close together. (4) Practice is said to improve the thermal sense. (5) Sensations of heat and cold may curiously alternate; thus when the skin is dipped first into water at 10° C. we feel cold, and if it be then dipped into water at 16° C. we have at first a feeling of warmth, but soon again of cold. (6) The same temperature applied to a large area is not appreciated in the same way as when applied to a small one; thus "the whole hand when placed in water at 29·5° C. feels warmer than when a finger is dipped into water at 32° C."

There is every reason to hold that there are different nerve fibres and different central organs for the tactile and thermal sensations, but nothing definite is known. The one sensation undoubtedly affects the other. Thus the minimum distance at which two compass points are felt is diminished when one point is warmer than the other. Again, a colder weight is felt as heavier, "so that the apparent difference of pressure becomes greater when the heavier weight is at the same time colder, and less when the lighter weight is colder, and difference of pressure is felt with equal weights of unequal temperature" (E. H. Weber). Great sensibility to differences of temperature is noticed after removal, alteration by vesicants, or destruction of the epidermis, and in the skin affection called herpes zoster. The same occurs in some cases of locomotor ataxy. Removal of the epidermis, as a rule, increases tactile sensibility and the sense of locality. Increased tactile sensibility is termed *hyperpselaphesia*, and is a rare phenomenon in nervous diseases. Paralysis of the tactile sense is called *hypopselaphesia*, whilst its entire loss is *apselaphesia*. Brown-Séquard mentions a case in which contact of two points gave rise to a sense of a third point of contact. Certain conditions of the nerve centres affect the senses both of touch and temperature. Under the influence of morphia the person may feel abnormally enlarged or diminished in size. As a rule the senses are affected simultaneously, but cases occur where one may be affected more than the other.

Sensations of heat and cold are chiefly referred to the skin, and only partially to some mucous membranes, such as those of the alimentary canal. Direct irritation of a nerve does not give rise to these sensations. The exposed pulp of a diseased tooth, when irritated by hot or cold fluids, gives rise to pain, not to sensations of temperature. It has now been ascertained that there are minute areas on the skin in which sensations of *heat* and *cold* may be more acutely felt than in adjoining areas; and, further, that there are points stimulated by addition of heat, hot spots, while others are stimulated by withdrawal of heat, cold spots.

A simple method of demonstrating this phenomenon is to use a solid cylinder of copper, 8 in. in length by ½ in. in thickness, and sharpened at one end to a fine pencil-like point. Dip the pointed end into very hot water, close the eyes, and touch parts of the skin. When a hot spot is touched, there is an acute sensation of burning. Such a spot is often near a hair. Again, in another set of experiments, dip the copper pencil into ice-cold water and search for cold spots. When one of these is touched, a sensation of cold, as if concentrated on a point, is experienced. Thus it may be demonstrated that in a given area of skin there may be hot spots, cold spots and touch spots.

Cold spots are more abundant than hot spots. The spots are arranged in curved lines, but the curve uniting a number of cold spots does not coincide with the curve forming a chain of hot spots. By Weber's method it will be found that we can discriminate cold spots at a shorter distance from each other than hot spots. Thus on the forehead cold spots have a minimum distance of 8 mm., and hot spots 4 mm.; on the skin of the breast, cold spots 2 mm., and hot spots 5 mm.; on the back, cold spots 1·5 mm., and hot spots 4 to 6 mm.; on the back of the hand, cold spots 3 mm., and hot spots 4 mm.; on the palm, cold spots 8 mm., and hot spots 2 mm.; and on the thigh and leg, cold spots 3 mm., and hot spots 3·5 mm. Electrical and mechanical stimulation of the hot or cold spots call forth the corresponding sensation. No terminal organ for discrimination of temperature has yet been found. It will be observed that the sensation of heat or cold is excited by *change* of temperature, and that it is more acute and definite the more sudden the change. Thus discrimination of temperature is similar to discrimination of touch, which depends on more or less sudden change of pressure. The term cold means, physiologically, the sensation we experience when heat is abstracted, and the term heat, the sensation felt when heat is added to the part. Thus we are led to consider that the skin contains at least two kinds of specific terminal organs for sensations of touch and temperature, and two sets of nerve fibres which carry the nervous impulses to the brain. In all probability, also, these fibres have different central endings, and in their course to the brain run in different tracts in the spinal cord. This will explain cases of disease of the central nervous system in which, over certain areas of skin, sensations of touch have been lost while sensations of temperature and pain remain, or vice versa. Tactile and thermal impressions may influence each other. Thus a leg sent to "sleep" by pressure on the sciatic nerve will be found to be less sensitive to heat, but distinctly sensitive to cold. In some cases of disease it has been noticed that the skin is sensitive to a temperature above that of the limb, but insensitive to cold. It is highly probable that just as we found in the case of touch (pressure), the terminal organs connected with the sense of temperature are the fine nerve filaments that have been detected in the deeper strata of the Malpighian region of the epidermis, immediately above the true skin, and it is also probable that certain epidermic (epithelial) cells in that region play their part in the mechanism. Sensations of a painful character may also, in certain circumstances, be referred to the viscera, and to mucous and serous surfaces. Pain is not a sensation excited by irritating the end organs either of touch or of temperature, nor even by irritating directly the filaments of a sensory nerve. Even if sensory nerves are cut or bruised, as in surgical operations, there may be no sensations of pain; and it has been found that muscles, vessels and even the viscera, such as the heart, stomach, liver or kidneys, may be freely handled without giving rise to any feeling of pain, or indeed to any kind of sensation. These parts, in ordinary circumstances appear to be insensitive, and yet they contain afferent nerves. If the sensibility of these nerves is heightened, or possibly if the sensitiveness of the central terminations of the nerves is raised, then we may have sensations to which we give the name of pain. In like manner the skin is endowed with afferent nerves, distinct from those ministering to touch and to temperature, along which nervous impulses are constantly flowing. When these nervous impulses reach the central nervous system in ordinary circumstances they do not give rise to changes that reach the level of consciousness, but they form, as it were, the warp and woof of our mental life, and they also affect metabolisms, that is to say, nutritive changes in many parts of the body. They may also, as is well known, affect unconsciously such mechanisms as those of the action of the heart, the calibre of the blood-vessels and the movements of respiration. If, however, this plane of activity is raised, as by intermittent pressure, or by inflammatory action, or by sudden changes of temperature, as in burning, scalding, &c., such nervous impulses give rise to pain. Sometimes pain is distinctly located, and in other cases it may be irradiated in the nerve centres, and referred to areas of skin or to regions of the body which are not really the seat of the irritation. Thus irritation of the liver may cause pain in the shoulder; disease of the hip-joint often gives rise to pain in the knee; and renal colic, due to the passage of a calculus down the ureter, to severe pain even in the abdominal walls. These are often termed *reflex pains* and their interpretation is of great importance to physicians in the diagnosis of disease. Their frequent occurrence has also directed attention to the distribution in the skin and termination in the brain of the sensory nerves. It is also noticeable that a sensation of pain gives us no information as to its cause; we simply have an agonizing sensation in a part to which, hitherto, we probably referred no sensations. The acuteness or intensity of pain depends partly on the intensity of the irritation, and partly on the degree of excitability of the sensory nerves at the time.

Pain.—In addition to sensations of touch and of temperature referred to the skin, there is still a third kind of sensation, unlike either, namely, pain. This sensation cannot be supposed to be excited by irritations of the end organs of touch, or of specific thermal end organs (if there be such), but rather to irritation of ordinary sensory nerves, and there is every reason to believe that painful impressions make their way to the brain along special tracks in the spinal cord. If we consider our mental condition as regards sensation at any moment, we notice numerous sensations more or less definite, not referred directly to the surface, nor to external objects, such as a feeling of general comfort, free or impeded breathing, hunger, thirst, malaise, horror, fatigue and pain. These are all caused by the irritation of ordinary sensory nerves in different localities, and if the irritation of such nerves, by chemical, thermal, mechanical or nutritional stimuli, passes beyond a certain maximum point of intensity the result is pain. Irritation of a nerve, in accordance with the law of "peripheral reference of sensation," will cause pain. Sometimes the irritation applied to the trunk of a sensory nerve may be so intense as to destroy its normal function, and loss of sensation or anaesthesia results. If then the stimulus be increased further, pain is excited which is referred to the end of the nerve, with the result of producing what has been called *anaesthesia dolorosa.* Pains frequently cannot be distinctly located, probably owing to the fact of irradiation in the nerve centres and subsequent reference to areas of the body which are not really the seat of irritations. The intensity of pain depends on the degree of excitability of the sensory nerves, whilst its massiveness depends on the number of nerve fibres affected. The quality of the pain is probably produced by the kind of irritation of the nerve, as affected by the structure of the part and the greater or less continuance of severe pressure. Thus there are piercing, cutting, boring, burning, throbbing, pressing, gnawing, dull and acute varieties of pain. Sometimes the excitability of the cutaneous nerves is so great that a breath of air or a delicate touch may give rise to suffering. This *hyperalgia* is found in inflammatory affections of the skin. In *neuralgia* the pain is characterized by its character of shooting along the course of the nerve and by severe exacerbations. In many nervous diseases there are disordered sensations referred to the skin, such as alternations of heat and cold, burning, creeping, itching and a feeling as if insects were crawling on the surface (formication). This condition is termed *paralgia.* The term *hypalgia* is applied to a diminution and *analgia* to paralysis of pain, as is produced by anaesthetics.

Muscular Sense.—The sensory impressions considered in this article are closely related to the so-called muscular sense, or that sense or feeling by which we are aware of the state of the muscles of a limb as regards contraction or relaxation. Some have held that the muscular sense is really due to greater or less stretching of the skin and therefore to irritation of the nerves of that organ. That this is not the case is evident from the fact that disordered movements indicating perversion or loss of this sense are not affected by removal of the skin (Claude Bernard). Further, cases in the human being have been noticed where there was an entire loss of cutaneous sensibility whilst the muscular sense was unimpaired. It is also known that muscles possess sensory nerves, giving rise, in certain circumstances, to fatigue, and, when strongly irritated, to the pain of cramp. Muscular sensations are really excited by irritation of sensory nerves passing from the muscles themselves. There are specialized spindle-like bodies in many muscles, and there are organs connected with tendons which are regarded as sensory organs by which pressures are communicated to sensory-nerve-filaments. We are thus made conscious of whether or not the muscles are contracted, and of the amount of contraction necessary to overcome resistance, and this knowledge enables us to judge of the amount of voluntary impulse. Loss or diminution of the muscular sense is seen in chorea and especially in locomotor ataxy. Increase of it is rare, but it is seen in the curious affection called *anxietas tibiarum,* a painful condition of unrest, which leads to a continual change in the position of the limbs (see EQUILIBRIUM).

(J. G. M.)

TOUL, a garrison town of north-eastern France, capital of an arrondissement in the department of Meurthe-et-Moselle, 21 m. W. of Nancy on the Eastern railway Pop. (1906), town 9523; commune, 13,663. Toul is situated in a plain on the left bank of the Moselle, which skirts the town on the S. and S. E., while on the N. it is bordered by the Marne-Rhine canal. It is principally important as being the centre of a great entrenched camp close to the German frontier. Immediately after the Franco-German War the whole system of frontier defence was revised, and of all the new fortresses of the Meuse and Moselle Toul is perhaps the most formidable. The works were begun in 1874 by the construction of four outlying forts north, north-east and south of the town, but these soon became merely an inner line of defence. The principal defences now lie much farther out on all sides. The west front of the new line of forts occupies a long line of high ground (the watershed of the Meuse and the Moselle), the north front, about 4 m. from Toul, is in undulating country, while facing towards Nancy and forming the chord of the arc which the Moselle describes from Fontenay below to Villey-le-Sec above, is the strong east front, the outlying works of which extend far to the east (Fort Frouard and other works about Nancy) and to the south-east (Pont St Vincent). The south front extends from the Moselle at Villey-le-Sec south-westwards till it meets the southern end of the west front on the high ground overlooking the Meuse valley. The fort at Pagny on the Meuse to the south-west may be considered an outwork of this line of defence. The perimeter of the Toul defences proper is nearly 30 m., and their mean distance from the town about 6 m. Northward, along the Meuse, Toul is connected with the fortress of Verdun by the " Meuse line " of barrier forts, the best known of which are Gironville, Liouville and Troyon. South of Toul the country was purposely left unfortified as far as Épinal (*q.v.*) and this region is known as the Trouée d'Épinal.

The town itself forms an oval within a bastioned enceinte pierced by three gateways. It has two important churches. That of St Étienne (formerly a cathedral) has a choir and transept of the 13th century; the nave and aisles are of the 14th, and the façade, the finest part of the building, of the last half of the 15th. The two western towers, which have no spires, reach a height of 246 ft. The two large lateral chapels of the nave are in the Renaissance style. The chief features of the interior are its stained glass and organ loft. South of the church there is a fine cloister of the end of the 13th century which was much damaged at the Revolution. The church of St Gengoult, which dates chiefly from the late 13th or early 14th century, has a façade of the 15th century and a cloister in the Flamboyant Gothic style of the 16th century. The hôtel-de-ville occupies a building of the 18th century, once the episcopal palace, and contains the library and museum. Toul is the seat of a sub-prefect and has a tribunal of commerce and a communal college among its public institutions. The industries include the manufacture of porcelain; trade is in wine and brandy.

Toul (*Tullum*) is one of the oldest towns of France; originally capital of the Leuci, in the Belgic Confederation, it acquired great importance under the Romans. It was evangelized by St Mansuy in the latter half of the 4th century, and became one of the leading sees of north-east Gaul. After being sacked successively by Goths, Burgundians, Vandals and Huns, Toul was conquered by the Franks in 450. Under the Merovingians it was governed by counts, assisted by elective officers. The bishops became sovereign counts in the 10th century, holding only of the emperor, and for a period of 300 years (13th to 16th centuries) the citizens maintained a long struggle against them. Together with Verdun and Metz the town and its domain formed the territory of the Trois-Evêchés. Toul was forced to yield for a time to the count of Vaudémont in the 12th century, and twice to the duke of Lorraine in the 15th, and was thrice devastated by the plague in the 16th century. Charles V. made a solemn entry into the town in 1544, but in the following year, at the instance of the cardinal of Lorraine, it placed itself under the perpetual protection of the kings of France. Henry II. took possession of the Trois-Evêchés in 1552, but the territory was not officially incorporated with France till 1648. Henry IV. was received in state in 1603, and in 1637 the parlement of Metz was transferred to Toul. In 1700 Vauban reconstructed the fortifications of the town. In 1790 the bishopric was suppressed and the diocese united to that of Nancy. Toul, which had then no modern defences, capitulated in 1870 after a bombardment of twelve days.

TOULON, a seaport and first-class fortress and naval station of France, department of Var, capital of the arrondissement of Toulon, on the Mediterranean, 42 m. E.S.E. of Marseilles. Pop. (1886), 53,941; (1901), 101,602. The bay, which opens to the east, has two divisions, the Grande Rade and the Petite Rade; it is sheltered on the north and west by high hills, closed on the south by the peninsula of capes Sicié and Cépet, and protected on the east by a huge breakwater, the entrance, 1300 ft. wide, being defensible by torpedoes. A ship coming from the open sea must first pass the forts of St Marguerite, of Cap Brun, of Lamalgue and of St Louis to the north, and the battery of the signal station to the south; before reaching the Petite Rade it must further pass under the guns of the battery of Le Salut to the east, and of the forts of Balaguier and L'Aiguillette to the west. The Bay of La Seyne lies west of the Petite Rade, and is defended by the forts of Six-Fours, Napoléon (formerly Fort Caire), and Malbousquet, and the batteries of Les Arènes and Les Gaus. To the north of Toulon rise the defensive works of Mont Faron and Fort Rouge, to the east the forts of Artigues and St Catherine, to the north-east the formidable fort of Coudon, and to the south-east that of Colle Noire, respectively dominating the highway into Italy and the valley of Hyères with the Bay of Carqueiranne. The town, enlarged to the north under the Second Empire, has on that side a fine modern quarter; but in the old town the streets are for the most part narrow, crooked and dirty, and to their insanitary state the cholera epidemic of 1884 was attributed. The chief buildings are the former cathedral of St Marie Majeure (from the 5th century Toulon was a bishop's see till 1801, when it was annexed to that of Fréjus), the church of St Louis, the naval and military hospital, with a natural history collection and an anatomical museum attached, a naval school of medicine, a school of hydrography, and large barracks. In 1883–1887 a handsome Renaissance building was erected to accommodate the picture gallery and the town library. The monument in commemoration of the centenary of the French Revolution was erected in 1890 in the Place de la Liberté, the finest in the new town. The imports are wine, corn, wood, coal, hemp, iron, sugar, coffee and fresh fish; the exports are salt, copper ore, barks for tanning and oils. The principal industries, apart from the arsenal, are shipbuilding, fishing, lace-making and wine-growing. Toulon possesses an observatory and a botanical garden. The interesting buildings and gardens of the hospital of St Mandrier stand on the peninsula of Cape Cépet, and near them is the *lazaretto.*

Toulon is the most important of the French dockyards, and is the headquarters of the Mediterranean fleet. The arsenal, which was created by Louis XIV.—Vauban being the engineer of the works—lies on the north side of the Petite Rade. This is approached from the Grande Rade by passages at the north and south ends of a long breakwater which extends from the direction of Le Mourillon towards the Cépet Peninsula. The water space within the moles amounts to about 150 acres, while the quays approach 4 m. in length. Outside in the Petite Rade is a splendid protected anchorage for a great fleet, the whole being commanded by many forts and batteries. There are four great basins approached from the Petite Rade—the Vielle Darse, to the east, on the side of Le Mourillon; the Darse Vauban, next to it; and the Darse de Castigneau and the Darse Missiessy, farther to the west. In the Darse Vauban are three dry docks, two of them 246 ft. long, with a depth of water on the sill of about 20 ft.; while the third is 283 ft. long, with a depth of over 24 ft. Three other dry docks are in the Darse de Castigneau, of which one is in two sections. The largest of the docks is 385 ft. long, and the depth of water on the sill in all these docks averages 30 ft. In the Darse Missiessy are two dry docks, 426 ft. long, with a depth on the sill of over 32 ft. There are several building slips, and the yard is supplied with a gun foundry and wharf, fitting-shops, boiler works, victualling and other establishments, rolling mills and magazines. Le Mourillon is a subsidiary yard at Toulon, devoted chiefly to ship-building, and possessing large facilities, including five covered slips.

The Roman Telo Martius is supposed to have stood near the lazaretto. The town was successively sacked by Goths, Burgundians, Franks and Saracens. During the early middle ages, and till conquered by Charles of Anjou in 1259, it was under lords of its own, and entered into alliance with the republics of Marseilles and Arles. St Louis, and especially Louis XII. and Francis I. strengthened its fortifications. It was seized by the emperor Charles V. in 1524 and 1536. Henry IV. founded a naval arsenal at Toulon, which was further strengthened by Richelieu, and Vauban made the new dock, a new enceinte, and several forts and batteries. In 1707 the town was unsuccessfully besieged by the duke of Savoy, Prince Eugene and an English fleet. In 1720 there was an outbreak of the plague. In 1792 after great and sanguinary disorder, the royalists of the town sought the support of the English and Spanish fleets cruising in the neighbourhood. The Convention having replied by putting the town "hors la loi," the inhabitants opened their harbour to the English. The army of the republic now (1793) laid siege to the town, and on this occasion Napoleon Bonaparte first made his name as a soldier. The forts commanding the town having been taken, the English ships retired after setting fire to the arsenal. The conflagration was extinguished by the prisoners, but not before 38 out of a total of 56 vessels had been destroyed. Under the Directory Toulon became the most important French military fort on the Mediterranean; here Napoleon organized the Egyptian campaign, and the expedition against Algiers set out from Toulon in 1830. The fortifications have been strengthened by Napoleon I., Louis Philippe, Napoleon III., and since 1870.

Battle of Toulon.—This naval battle took place on the 11th of February 1744, near the port of Toulon. A British fleet of thirty sail of the line under command of Thomas Mathews, who combined the offices of naval commander-in-chief in the Mediterranean and envoy to the courts of Sardinia and the Italian princes, engaged a combined force of Spaniards under Don José Navarro and French under M. de Court. They were in all twenty-seven sail. The allies left Toulon on the 9th of February. Mathews was at anchor in Hyères Bay to watch them, for though France and Great Britain were already engaged as allies on opposite sides in the War of the Austrian Succession, there had been no declaration of war between them. It was known that the allies meant to transfer Spanish troops to Italy to serve against the Austrians, and Mathews had no hesitation in attacking them, Great Britain being at war with Spain. He left Hyères in very light wind with a heavy westerly swell, and with his fleet in confusion. The British ships were straggling over a distance of ten miles, but he put himself between the enemy and Toulon. Mathews was on bad terms with his second in command, Lestock, who commanded the rear division and showed little disposition to support his superior. By the morning of the 11th the interval between the van and centre of the British fleet and its rear had increased in the light breezes, and also through the voluntary or involuntary misapprehension of Mathews's orders by Lestock. The allies were in a fairly well-formed line, heading to the south, and southward of the British. Mathews pursued, and at 1.30 p.m., when his leading ship was abreast of the centre ship of the allies, he attacked. Some hot fighting took place between Mathews and the Spaniards who formed the allied rear. The action was notable as the last occasion on which an attempt was made to use a fireship on the open sea. One was sent against the "Real" (114), the Spanish flagship, but she was reduced to a sinking state by the fire of the Spaniards, and blew up prematurely, with the loss of all on board. At about five o'clock, the French in the van turned back to support the Spaniards, and Mathews drew off. One Spanish ship, the "Poder" (60), which had surrendered was recaptured, and then set on fire by the allies. Mathews made only a feeble attempt to renew the battle on the following days, and on the 13th returned towards the coast of Italy, which he said he had to defend. The British rear division had not come into action at all.

The battle, though a miserable affair in itself, is of great importance in naval history because of the pronouncement of doctrine to which it led. Mathews, who was dissatisfied with his subordinate, Lestock, suspended him from command and sent him home for trial. Several of the captains had behaved ill, and the failure of a superior British fleet to gain a success over the allies caused extreme discontent at home. A parliamentary inquiry was opened on the 12th of March 1745, which on the 18th of April, after a confused investigation, ended in a petition to the king to order trials by court-martial of all the officers accused of misconduct. A long series of courts-martial began on the 11th of September 1745, and did not end till the 22nd of October 1746. Several captains were sentenced to be dismissed the service. Lestock was acquitted, but Mathews was condemned and sentenced to dismissal. The finding of the court, which blamed the officer who actually fought, and acquitted the other who did not, puzzled and angered public opinion. The technical points were not appreciated by laymen. The real evil done by the condemnation of Mathews was not understood even in the navy. Mathews was blamed on the ground that he had not waited to engage till his van ship was abreast of the van ship of the enemy. By this declaration of principle the court confirmed the formal system of naval tactics which rendered all sea-fighting between equal or nearly equal forces so ineffective for two generations.

See Beatson, *Naval and Military Memoirs*, i. 197 seq. (London, 1804), a full and fair narrative. (D. H.)

TOULOUSE, LOUIS ALEXANDRE DE BOURBON, Count of (1678–1737), third son of Louis XIV. and Mme de Montespan was born on the 6th of June 1678. At the age of five he was created admiral of France. He distinguished himself during the War of the Spanish Succession, and inflicted a severe defeat on Admiral Rooke near Malaga in 1704. He kept aloof from the intrigues of his sister-in-law, the duchess of Maine, and died on the 1st of December 1737. His son, Louis Jean Marie de Bourbon, duc de Penthièvre (1725–1793), succeeded his father in his posts, among others in that of grand admiral. He served under Marshal de Noailles, and fought brilliantly at Dettingen (1743) and Fontenoy (1745). He then lived in retreat at Rambouillet and Sceaux, protecting men of letters, and particularly the poet Florian, and dispensing charity. He lost his son, the prince of Lamballe, in 1768, and survived his daughter-in-law, Louise Marie Thérèse of Savoy-Carignan, the friend of Marie Antoinette, who was killed by the populace on the 3rd of September 1792. He died on the 4th of March 1793; his daughter and heiress, Louise Marie Adélaïde, married Philippe (Égalité), duke of Orleans.

TOULOUSE, a city of south-western France, capital of the department of Haute-Garonne, 443 m. S. by W. of Paris by the Orleans railway, and 159 m. S.E. of Bordeaux by the Southern railway. Pop. (1906), town, 125,856; commune, 149,438. Toulouse is situated on the right bank of the Garonne, which here changes a north-easterly for a north-westerly direction, describing a curve round which the city extends in the form of a crescent. On the left bank is the suburb of St Cyprien, which is exposed to the inundations of the river owing to its low situation. The river is spanned by three bridges—that of St Pierre to the north, that of St Michel to the south, and the Pont Neuf in the centre; the last, a fine structure of seven arches was begun in 1543 by Nicolas Bachelier, the sculptor, whose work is to be seen in many of the churches and mansions of the city. East and north of the city runs the Canal du Midi, which here joins the lateral canal of the Garonne. Between the Canal du Midi and the city proper extends a long line of boulevards leading southwards by the Allée St Étienne to the Grand Rond, a promenade whence a series of allées branch out in all directions. South-west the Allée St Michel leads towards the Garonne, and south the Grande Allée towards the Faubourg St Michel. These boulevards take the place of the old city walls. Between them and the canal lie the more modern faubourgs of St Pierre, Arnaud-Bernard, Matabiau, &c. The Place du Capitole, to which streets converge from every side, occupies the centre of the city. Two broad straight thoroughfares of modern construction, the Rue de Metz and the Rue d'Alsace-Lorraine, intersect one another to the south of this point, the first running east from the Pont Neuf, the other running north and south. The other streets are for the most part narrow and irregular.

The most interesting building in Toulouse is the church of St Sernin or Saturnin, whom legend represents as the first preacher of the gospel in Toulouse, where he was perhaps martyred about the middle of the 3rd century. The choir, the oldest part of the present building, was consecrated by Urban II. in 1096. The church is the largest Romanesque basilica in existence, being 375 ft. from east to west and 210 ft. in extreme breadth. The nave (12th and 13th centuries) has double aisles. Four pillars, supporting the central tower, are surrounded by heavy masonry, which somewhat spoils the general harmony of the interior. In the southern transept is the "portail des comtes," so named because near it lie the tombs of William Taillefer, Pons, and other early counts of Toulouse. The little chapel in which these tombs (ascribed to the 11th century) are found was restored by the capitols of Toulouse in 1648. Another chapel contains a Byzantine Christ of late 11th-century workmanship. The choir (11th and 12th centuries) ends in an apse, or rather chevet, surrounded by a range of columns, marking off an aisle, which in its turn opens into five chapels. The stalls are of 16th-century work and grotesquely carved. Against the northern wall is an ancient *table d'autel*, which an 11th-century inscription declares to have belonged to St Sernin. In the crypts are many relics, which, however, were robbed of their gold and silver shrines during the Revolution. On the south there is a fine outer porch in the Renaissance style; it is surmounted by a representation of the Ascension in Byzantine style. The central tower (13th century) consists of five storeys, of which the two highest are of later date, but harmonize with the three lower ones. A restoration of St Sernin was carried out in the 19th century by Viollet-le-Duc.

The cathedral, dedicated to St Stephen, dates from three different epochs. The walls of the nave belong to a Romanesque cathedral of the 11th century, but its roof dates from the first half of the 13th century. The choir was begun by Bishop Bertrand de l'Ile (*c.* 1272), who wished to build another church in place of the old one. This wish was unfulfilled and the original nave, the axis of which is to the south of that of the choir, remains. The choir was burned in 1690 but restored soon after. It is surrounded by seventeen chapels, finished by the cardinal d'Orléans, nephew of Louis XI., about the beginning of the 16th century, and adorned with glass dating from the 15th to the 17th century. The western gate, flanked by a huge square tower, was constructed by Peter du Moulin, archbishop of Toulouse, from 1439 to 1451. It has been greatly battered, and presents but a poor approximation to its ancient beauty. Over this gate, which was once ornamented with the statues of St Sernin, St Exuperius and the twelve apostles, as well as those of the two brother archbishops of Toulouse, Denis (1423–1439) and Peter du Moulin, there is a beautiful 13th-century rose-window, whose centre, however, is not in a perpendicular line with the point of the Gothic arch below.

Among other remarkable churches may be noticed Notre-Dame de la Daurade, near the Pont Neuf, built on the site of a 9th-century Benedictine abbey and reconstructed towards the end of the 18th century; and Notre-Dame de la Dalbade; perhaps existing in the 11th, but in its present form dating from the 16th century, with a fine Renaissance portal. The church of the Jacobins, held by Viollet-le-Duc to be "one of the most beautiful brick churches constructed in the middle ages," was built towards the end of the 13th century, and consists of a nave divided into two aisles by a range of columns. The chief exterior feature is a beautiful octagonal belfry. The church belonged to a Dominican monastery, of which part of the cloister, the refectory, the chapter-hall and the chapel also remain and are utilized by the lycée. Of the other secular buildings the most noteworthy are the capitole and the museum. The capitole has a long Ionic façade built from 1750 to 1760. The theatre is situated in the left wing. Running along almost the whole length of the first floor is the *salle des illustres* adorned with modern paintings and sculptures relating to the history of the town. The museum (opened in 1795) occupies, besides a large modern building, the church, cloisters and other buildings of an old Augustinian convent. It contains pictures and a splendid collection of antiquities, notably a series of statues and busts of Roman emperors and others and much Romanesque sculpture. There is an auxiliary museum in the old college of St Raymond. The natural history museum is in the Jardin des Plantes. The law courts stand on the site of the old Château Narbonais, once the residence of the counts of Toulouse and later the seat of the parlement of Toulouse. Near by is a statue of the jurist Jacques Cujas, born at Toulouse.

Toulouse is singularly rich in mansions of the 16th and 17th centuries. Among these may be mentioned the Hôtel Bernuy, a fine Renaissance building now used by the lycée and the Hôtel d'Assézat of the same period, now the property of the *Académie des Jeux Floraux* (see below), and of the learned societies of the city. In the court of the latter there is a statue of Clémence Isaure, a lady of Toulouse, traditionally supposed to have enriched the Académie by a bequest in the 15th century. The Maison de Pierre has an elaborate stone façade of 1612.

Toulouse is the seat of an archbishopric, of a court of appeal, a court of assizes and of a prefect. It is also the headquarters of the XVII. army corps and centre of an educational circumscription (*académie*). There are tribunals of first instance and of commerce, a board of trade-arbitration, a chamber of commerce and a branch of the Bank of France. The educational institutions include faculties of law, medicine and pharmacy, science and letters, a Catholic institute with faculties of theology and letters, higher and lower ecclesiastical seminaries, lycées and training colleges for both sexes, and schools of veterinary science, fine arts and industrial sciences and music.

Toulouse, the principal commercial and industrial centre of Languedoc, has important markets for horses, wine, grain, flowers, leather, oil and farm produce. Its pastry and other delicacies are highly esteemed. Its industrial establishments include the national tobacco factory, flour-mills, saw-mills, engineering workshops and factories for farming implements, bicycles, vehicles, artificial manures, paper, boots and shoes, and flour pastes.

Tolosa, chief town of the Volcae Tectosages, does not seem to have been a place of great importance during the early centuries of the Roman rule in Gaul, though in 106 B.C. the pillage of its temple by Q. S. Cepio, afterwards routed by the Cimbri, gave rise to the famous Latin proverb *habet aurum Tolosanum*, in allusion to ill-gotten gains. It possessed a circus and an amphitheatre, but its most remarkable remains are to be found on the heights of Old Toulouse (*vetus Tolosa*) some 6 or 7 m. to the east, where huge accumulations of broken pottery and fragments of an old earthen wall mark the site of an ancient settlement. The numerous coins that have been discovered on the same spot do not date back farther than the 2nd century B.C., and seem to indicate the position of a Roman manufacturing centre then beginning to occupy the Gallic hill-fortress that, in earlier days, had in times of peril been the stronghold of the native tribes dwelling on the river bank. Tolosa does not seem to have been a Roman colony; but its importance must have increased greatly towards the middle of the 4th century. It is to be found entered in more than one itinerary dating from about this time; and Ausonius, in his *Ordo nobilium urbium*, alludes to it in terms implying that it then had a large population. In 419 it was made the capital of his kingdom by Wallia, king of the Visigoths, under whom or whose successors it became the seat of the great Teutonic kingdom of the West-Goths—a kingdom that within fifty years had extended itself from the Loire to Gibraltar and from the Rhone to the Atlantic. On the defeat of Alaric II. (507) Toulouse fell into the hands of Clovis, who carried away the royal treasures to Angoulême. Under the Merovingian kings it seems to have remained the greatest city of southern Gaul, and is said to have been governed by dukes or counts dependent on one or other of the rival kings descended from the great founder of the Frankish monarchy. It figures prominently in the pages of Gregory of Tours and Sidonius Apollinaris. About 628 Dagobert erected South Aquitaine into a kingdom for his brother Charibert, who chose Toulouse as his capital. For the next eighty years its history is obscure, till we reach the days of Charles Martel, when it was besieged by Sema, the leader of the Saracens from Spain (*c.* 715–720), but delivered by Eudes, "princeps Aquitaniae," in whom later writers discovered the ancestor of all the later counts of Toulouse. Modern criticism, however, has discredited this genealogy; and the real history of Toulouse recommences in 780 or 781, when Charlemagne appointed his little son Louis king of Aquitaine, with Toulouse for his chief city.

During the minority of the young king his tutor Chorson ruled at Toulouse with the title of duke or count. Being deposed at the Council of Worms (790), he was succeeded by William Courtnez, the traditional hero of southern France, who in 806 retired to his newly founded monastery at Gellone, where he died in 812. In the unhappy days of the emperor Louis the Pious and his children Toulouse suffered in common with the rest of western Europe. It was besieged by Charles the Bald in 844, and taken four years later by the Normans, who in 843 had sailed up the Garonne as far as its walls. About 852 Raymond I., count of Quercy, succeeded his brother Fridolo as count of Rouergue and Toulouse; it is from this noble that all the later counts of Toulouse trace their descent. Raymond I.'s grandchildren divided their parents' estates; of these Raymond II. (d. 924) became count of Toulouse, and Ermengaud, count of Rouergue, while the hereditary titles of Gothia, Quercy and Albi were shared between them. Raymond II.'s grandson, William Taillefer (d. *c.* 1037), married Emma of Provence, and handed down part of that lordship to his younger son Bertrand.[1] William's elder son Pons left two children, of whom William IV. succeeded his father in Toulouse, Albi, Quercy, &c.; while the younger, Raymond IV. of St Gilles (*c.* 1066), made himself master of the vast possessions of the counts of Rouergue, married his cousin the heiress of Provence, and about 1085 began to rule the immense estates of his elder brother, who was still living.

From this time the counts of Toulouse were the greatest lords in southern France. Raymond IV., the hero of the first crusade, assumed the formal titles of marquis of Provence, duke of Narbonne and count of Toulouse. While Raymond was away in the Holy Land, Toulouse was seized by William IX., duke of Aquitaine, who claimed the city in right of his wife Philippa, the daughter of William IV., but was unable to hold it long (1098–1100). Raymond's son and successor Bertrand followed his father's example and set out for the Holy Land in 1109, leaving his great estates at his death to his brother Alphonse Jourdain. The rule of this prince was disturbed by the ambition of William IX. and his grand-daughter Eleanor, who urged her husband Louis VII. to support her claims to Toulouse by war. On her divorce from Louis and her marriage with Henry II., Eleanor's claims passed on to this monarch, who at last forced Raymond V. to do him homage for Toulouse in 1173. Raymond V., the patron of the troubadours, died in 1194, and was succeeded by his son Raymond VI., under whose rule Languedoc was desolated by the crusaders of Simon de Montfort, who occupied Toulouse in 1215, but lost his life in besieging it in 1218. Raymond VII., the son of Raymond VI. and Princess Joan of England, succeeded his father in 1222, and died in 1249, leaving an only daughter Joan, married to Alfonso the brother of Louis IX. On the death of Alfonso and Joan in 1271 the vast inheritance of the counts of Toulouse lapsed to the Crown.[2] From the middle years of the 12th century the people of Toulouse seem to have begun to free themselves from the most oppressive feudal dues. An act of Alphonse Jourdain (1141) exempts them from the tax on salt and wine; and in 1152 we have traces of a "commune consilium Tolosae" making police ordinances in its own name "with the advice of Lord Raymond, count of Toulouse, duke of Narbonne, and marquis of Provence." This act is witnessed by six "capitularii," four duly appointed judges (*judices constituti*), and two advocates. Twenty-three years later there are twelve capitularii or consuls, six for the city and six for its suburbs, all of them elected and sworn to do justice in whatever municipal matters were brought before them. In 1222 their number was increased to twenty-four; but they were forbidden to touch the city property, which was to remain in the charge of certain "communarii" chosen by themselves. Early in the 14th century the consuls took the name of "domini de capitulo," or, a little later, that of "capitulum nobilium." From the 13th century the consuls met in their own house, the "palatium communitatis Tolosae" or hôtel-de-ville. In the 16th century a false derivation changed the ancient consuls (*domini de capitulo*) into the modern "capitouls" (*domini capitolii tolosani*), a barbarous etymology which in its turn has, in the present century, transformed the old assembly house of Toulouse into the capitole. The parlement of Toulouse was established as a permanent court in 1443. Louis XI. transferred it to Montpellier in 1467, but restored it to Toulouse before the close of the next year. This parlement was for Languedoc and southern France what the parlement of Paris was for the north. During the religious wars of the 16th century the Protestants of the town made two unsuccessful attempts to hand it over to the prince de Condé. After St Bartholomew's Day (1572) 300 of the party were massacred. Towards the end of the 16th century, during the wars of the League, the parlement was split up into three different sections, sitting respectively at Carcassonne or Béziers, at Castle Sarrasin, and at Toulouse. The three were reunited in 1596. Under Francis I. it began to persecute heretics, and in 1619 rendered itself notorious by burning the philosopher Vanini. In 1762 Jean Calas, an old man falsely accused of murdering his eldest son to prevent him becoming a Roman Catholic, was broken on the wheel. By the exertions of Voltaire his character was afterwards rehabilitated. The university of Toulouse owes its origin to the action of Gregory IX., who in 1229 bound Raymond VII. to maintain four masters to teach theology and eight others for canon law, grammar, and the liberal arts. Civil law and medicine were taught only a few years later. The famous "Floral Games" of Toulouse, in which the poets of Languedoc contended (May 1–3) for the prize of the golden amaranth and other gold or silver flowers, given at the expense of the city, were instituted in 1323–1324. The *Académie des Jeux Floraux* still awards these prizes for compositions in poetry and prose. In 1814 the duke of Wellington defeated Marshal Soult to the north-east of the town.

See L. Ariste and L. Brand, *Histoire populaire de Toulouse depuis les origines jusqu'à ce jour* (Toulouse, 1898). This work contains an exhaustive bibliography.

[1] About 975 there was a partition of the estates which William Taillefer and his cousin Raymond II. of Auvergne held in common,—Albi, Quercy, &c., falling to William, and Gothia, &c., to Raymond.

[2] List of the counts of Toulouse:

Chorson	778–790	Raymond III.	924–*c.* 950
William I.	790–806	William Taillefer	*c.* 950–*c.* 1037
Raymond Rafinel	*c.* 812–818	Pons	1037–1060
Berenger	818–835	William IV.	1060–*c.* 1093
Bernard I.	835–844	Raymond IV.	1093–1096
Warin	844–845	Bertrand	1096–1109
William II.	845–850	Alphonse Jourdain	1109–1148
Fridolo	850–852	Raymond V.	1148–1194
Raymond I.	852–864	Raymond VI.	1194–1222
Bernard	864–875	Raymond VII.	1222–1249
Eudo	875–918	Alfonso and Joan	1249–1271
Raymond II.	918–*c.* 924		

TOUNGOO, or TAUNG-NGU, a town and district in the Tenasserim division of Lower Burma. The town is situated on the right bank of the river Sittang, 166 m. by rail N. from Rangoon. Pop. (1901), 15,837. From the 14th to the 16th century it was the capital of an independent kingdom. After the second Burmese War it was an important frontier station, but the troops were withdrawn in 1893. The district of Toungoo has an area of 6172 sq. m.; pop. (1901), 279,315, showing an increase of 32% in the preceding decade. Three mountain ranges traverse the district—the Pegu Yomas, the Karen, and the Nat-taung or "Great Watershed"—all of which have a north and south direction, and are covered for the most part with dense forest. The Pegu Yomas have a general elevation of from 800 to 1200 ft., while the central range averages from 2000 to 3000 ft. The rest of Toungoo forms the upper portion of the valley of the Sittang, the only large river in the district, the chief tributaries of which are the Shwa, Hkabaung, Hpyu Thank-ye-Kat and Yank-thua-wa, all navigable for a great portion of their course. Limestone appears in various places, and in the north-east a light grey marble is quarried for lime. The rivers form the chief means of communication during the rainy season. The rainfall in 1905 was 80·30 in. There are 14 railway stations in the district. Rice is the staple crop; there are promising plantations of coffee and rubber. Forests cover more than 5000 sq. m., of which 1337 sq. m. have been reserved, yielding a large revenue.

TOUP, JONATHAN [JOANNES TOUPIUS] (1713–1785), English classical scholar and critic, was born at St Ives in Cornwall, and was educated at a private school and Exeter College, Oxford. Having taken orders, he became rector of St Martin's Exeter, where he died on the 19th of January 1785. Toup established his reputation by his *Emendationes in Suidam* (1760–1766, followed in 1775 by a supplement) and his edition of *Longinus* (1778), including notes and emendations by Ruhnken. The excellence of Toup's scholarship was "known to the learned throughout Europe" (so epitaph on the tablet in the church of East Looe set up by the delegates of the Clarendon Press), but his overbearing manner and extreme self-confidence made him many enemies.

TOURACOU, the name, evidently already in use, under which in 1743 G. Edwards figured a pretty African bird,[1] and presumably that applied to it in Guinea, whence it had been brought alive. It is the *Cuculus persa* of Linnaeus, and *Turacus* or *Corythaix persa* of later authors. Cuvier in 1799 or 1800 Latinized its native name (adopted in the meanwhile by both French and German writers) as above, for which barbarous term J. K. W. Illiger, in 1811, substituted a more classical word. In 1788 Isert described and figured (*Beobacht. Gesellsch. naturf. Freunde*, iii. 16–20, pl. 1) a bird, also from Guinea, which he called *Musophaga violacea*. Its affinity to the original Touracou was soon recognized, and both forms have been joined by modern systematists in the family Musophagidae, commonly Englished Plantain-eaters or Touracous.

(After Schlegel.)

White-Crested Touracou (*Turacus albicristatus*).

To take first the Plantain-eaters proper, or the genus *Musophaga*, of which only two species are known. One, about the size of a crow, is comparatively common in museums, and has the horny base of its yellow bill prolonged backwards over the forehead in a kind of shield. The top of the head and the primaries, except their outer edge and tip, are deep crimson; a white streak extends behind the eye; and the rest of the plumage is glossy purple. The second species, *M. rossae*, which is rare, chiefly differs by wanting the white eye-streak. Then of the Touracous—the species originally described is about the size of a jay, and has the head, crest (which is vertically compressed and tipped with red), neck and breast of grass-green, varied by two white streaks—one, from the gape to the upper part of the crimson orbit, separated by a black patch from the other, which runs beneath and behind the eye. The wing-coverts, lower part of the back, and tail are of steel-purple, the primaries deep crimson, edged and tipped with bluish black. Over a dozen other congeneric species, more or less resembling this, have been described, and all inhabit some district of Africa. One, found in the Cape Colony and Natal, where it is known as the "Lory" (cf. xv. 7, note 1), though figured by Daubenton and others, was first differentiated in 1841 by Strickland (*Ann. Nat. History*, vii. 33) as *Turacus albicristatus*—its crest having a conspicuous white border, while the steel-purple of *T. persa* is replaced by a rich and glossy bluish green of no less beauty. In nearly all the species of this genus the nostrils are almost completely hidden by the frontal feathers; but there are two others in which, though closely allied, this is not the case, and some systematists would place them in a separate genus *Gallirex*; while another species, the giant of the family, has been moved into a third genus as *Corythaeola cristata*. This differs from any of the foregoing by the absence of the crimson coloration of the primaries, and seems to lead to another group, *Schizorrhis*, in which the plumage is of a still plainer type, and, moreover, the nostrils here are not only exposed but in the form of a slit, instead of being oval as in all the rest. This genus contains about half-a-dozen species, one of which, *S. concolor*, is the Grey Touracou of the colonists in Natal, and is of an almost uniform slaty brown. A good deal has been written about these birds, which form the subject of a beautiful monograph —*De Toerako's afgebeld en beschreven*—by Schlegel and Westerman, brought out at Amsterdam in 1860; while further information is contained in an elaborate essay by Schalow (*Journ. f. ornithologie*, 1886, pp. 1–77). Still, much remains to be made known as to their distribution throughout Africa and their habits. They seem to be all fruit-eaters, and to frequent the highest trees, seldom coming to the ground. Very little can be confidently asserted as to their nidification, but at least one species of *Schizorrhis* is said to make a rough nest and therein lay three eggs of a pale blue colour. An extraordinary peculiarity attends the crimson coloration which adorns the primaries of so many of the Musophagidae. So long ago as 1818, Jules Verreaux observed (*Proc. Zool. Society*, 1871, p. 40) that in the case of *T. albicristatus* this beautiful hue vanishes on exposure to heavy rain and reappears only after some interval of time and when the feathers are dry.[2]

The Musophagidae form a distinct family, of which the Cuculidae are the nearest allies, the two being associated to form the Cuculine as compared with the Psittacine division of Cuculiform birds (see Bird and Parrot). T. C. Eyton pointed out (*Ann. Nat. History*, 3rd series, vol. ii. p. 458) a feature possessed in common by the latter and the Musophagidae, in the "process attached to the anterior edge of the ischium," which he likened to the so-called "marsupial" bones of Didelphian mammals. J. T. Reinhardt has also noticed (*Vidensk. meddels. naturhist. forening*, 1871, pp. 326–341) another Cuculine character offered by the *os uncinatum* affixed to the lower side of the ethmoid in the Plantain-eaters and Touracous; but too much dependence must not be placed on that, since a similar structure is presented by the frigate-bird (*q.v.*) and the petrels (*q.v.*). A corresponding process seems also to be found in Trogon (*q.v.*). The bill of nearly all the species of Musophagidae is curiously serrated or denticulated along the margin and the feet have the outer toe reversible, but usually directed backwards. No member of the family is found outside of the continental portion of the Ethiopian region. (A. N.)

TOURAINE, an old province in France, which stretched along both banks of the Loire in the neighbourhood of Tours, the river dividing it into Upper and Lower Touraine. It was bounded on the N. by Orléanais, W. by Anjou and Maine, S. by Poitou and E. by Berry, and it corresponded approximately to the modern department of Indre et Loire. Touraine took its name from the Turones, the tribe by which it was inhabited at the time of Caesar's conquest of Gaul. They were unwarlike, and offered practically no resistance to the invader, though they joined in the revolt of Vercingetorix in A.D. 52. The capital city, Caesarodunum, which was built on the site of the eastern part of the present city of Tours, was made by Valentinian the metropolis of the 3rd Lyonnaise, which included roughly the later provinces of Touraine, Brittany, Maine and Anjou. Christianity seems to have been introduced into Touraine not much earlier than the beginning of the 4th century, although tradition assigns St Gatien, the first bishop of Tours, to the 3rd. The most famous of its apostles was St Martin (*fl.* 375-400), who founded the abbey of Marmoutier, near Tours, and whose tomb in the city became a celebrated shrine. Tours was besieged by the Visigoths in 428, and though it offered a successful resistance on this occasion it was included fifty years later in the territory of the Visigoths. The Tourangeans refused to adopt the Arian heresy of their conquerors, and this difference in religion materially assisted in 507 the conquest of the province by Clovis, whose orthodoxy was guaranteed by the miraculous intervention of St Martin. St Clotilda, wife of Clovis, spent the last years of her life in retreat at Tours. The possession of Touraine was constantly the subject of dispute between the Merovingian princes, and the province enjoyed no settled peace until the reign of Charlemagne. He established Alcuin as abbot of St Martin of Tours, and under his auspices the school of Tours became one of the chief seats of learning in

[1] Apparently the first ornithologist to make the bird known was Albin, who figured it in 1738 from the life, yet badly, as "The Crown-bird of Mexico." He had doubtless been misinformed as to its proper country; but Touracous were called "Crown-birds" by the Europeans in West Africa, as witness Bosman's *Description of the Coast of Guinea* (2nd ed., 1721), p. 251, and W. Smith's *Voyage to Guinea* (1745), p. 149, though the name was also given to the crowned cranes, *Balearica*.

[2] The fact of this colouring matter being soluble in water was incidentally mentioned at a meeting of the Zoological Society of London by W. B. Tegetmeier, and brought to the notice of Professor A. H. Church, who, after experiment, published in 1868 (*Student and Intellectual Observer*, i. 161–168) an account of it as "Turacin, a new animal pigment containing copper." Further information on the subject was given by Monteiro (*Chem. News*, xxviii. 201; *Quart. Journ. Science*, 2nd series, vol. iv. p. 132). The property is possessed by the crimson feathers of all the birds of the family.

the middle ages. In the 9th century Tours also became the ecclesiastical metropolis of Brittany, Maine and Anjou, and when the empire was divided by Louis the Pious into various districts or *missatica*, Tours was the centre of one of these, the boundaries of which corresponded roughly with those of the ecclesiastical jurisdiction of the city. Touraine suffered from the invasions of the Northmen, who massacred the monks of Marmoutier in 853, but never pillaged Tours. The administration of Touraine was entrusted, from Merovingian times onward, to counts appointed by the crown. The office became hereditary in 940 or 941 with Thibault the Old or the "Tricheur." His son Odo I. was attacked by Fulk the Black, count of Anjou, and despoiled of part of his territory. His grandson Thibault III., who refused homage to Henry I., king of France, in 1044, was entirely dispossessed by Geoffrey of Anjou, called the Hammer (d. 1060). The 7th count, Fulk (d. 1109), ruled both Anjou and Touraine, and the county of Touraine remained under the domination of the counts of Anjou (*q.v.*) until Henry II. of England deprived his brother Geoffrey of Touraine by force of arms. Henry II. carried out many improvements, but peace was destroyed by the revolt of his sons. Richard Coeur de Lion, in league with Philip Augustus, had seized Touraine, and after his death Arthur of Brittany was recognized as count. In 1204 it was united to the French crown, and its cession was formally acknowledged by King John at Chinon in 1214. Philip appointed Guillaume des Roches hereditary seneschal in 1204, but the dignity was ceded to the crown in 1312. Touraine was granted from time to time to princes of the blood as an appanage of the crown of France. In 1328 it was held by Jeanne of Burgundy, queen of France; by Philip, duke of Orleans, in 1344; and in 1360 it was made a peerage duchy on behalf of Philip the Bold, afterwards duke of Burgundy. It was the scene of dispute between Charles, afterwards Charles VII., and his mother, Isabel of Bavaria, who was helped by the Burgundians. After his expulsion from Paris by the English Charles spent much of his time in the châteaux of Touraine, although his seat of government was at Bourges. He bestowed the duchy successively on his wife Mary of Anjou, on Archibald Douglas and on Louis III. of Anjou. It was the dower of Mary Stuart as the widow of Francis II. The last duke of Touraine was Francis, duke of Alençon, who died in 1584. Plessis-les-Tours had been the favourite residence of Louis XI., who granted many privileges to the town of Tours, and increased its prosperity by the establishment of the silk-weaving industry. The reformed religion numbered many adherents in Touraine, who suffered in the massacres following on the conspiracy of Amboise; and, though in 1562 the army of Condé pillaged the city of Tours, the marshal of St André reconquered Touraine for the Catholic party. Many Huguenots emigrated after the massacre of St Bartholomew, and after the revocation of the Edict of Nantes the silk industry, which had been mainly in the hands of the Huguenots, was almost destroyed. This migration was one of the prime causes of the extreme poverty of the province in the next century. At the Revolution the nobles of Touraine made a declaration expressing their sympathy with the ideas of liberty and fraternity. Among the many famous men who were born within its boundaries are Jean le Meingre Boucicaut, marshal of France, Béroalde de Verville, author of the *Moyen de parvenir*, Rabelais, Cardinal Richelieu, C. J. Avisseau, the potter (1796–1861), the novelist Balzac and the poet Alfred de Vigny.

See the quarterly publication of the *Mémoires* of the *Société archéologique de Touraine* (1842, &c.) which include a *Dictionnaire géographique, historique et biographique* (6 vols., 1878–1884), by J. X. Carré de Busserolle. There are histories of Touraine and its monuments by Chalmel (4 vols. Paris, 1828), by S. Bellanger (Paris, 1845), by Bourrassé (1858). See also Dupin de Saint André, *Hist. du protestantisme en Touraine* (Paris, 1885); T. A. Cook, *Old Touraine* (2 vols. London, 1892).

TOURCOING, a manufacturing town of northern France in the department of Nord, less than a mile from the Belgian frontier, and 8 m. N.N.E. of Lille on the railway to Ghent. Pop. (1906), 62,694 (commune, 81,671), of whom about one-third are natives of Belgium. Tourcoing is practically one with Roubaix to the south, being united thereto by a tramway and a branch of the Canal de Roubaix. The public institutions comprise a tribunal of commerce, a board of trade arbitrators, a chamber of commerce, an exchange and a conditioning house for textiles. Together with Roubaix, Tourcoing ranks as one of the chief textile centres of France. Its chief industry is the combing, spinning and twisting of wool carried on in some eighty factories employing between 10,000 and 12,000 workpeople. The spinning and twisting of cotton is also important. The weaving establishments produce woollen and mixed woollen and cotton fabrics together with silk and satin drapery, swanskins, jerseys and other fancy goods. The making of velvet pile carpets and upholstering materials is a speciality of the town. To these industries must be added those of dyeing, the manufacture of hosiery, of the machinery and other apparatus used in the textile factories and of soap.

Famed since the 12th century for its woollen manufactures, Tourcoing was fortified by the Flemings in 1477, when Louis XI. of France disputed the inheritance of Charles the Bold with Mary of Burgundy, but in the same year was taken and pillaged by the French. In 1794 the Republican army, under Generals Moreau and Souham, gained a decisive victory over the Austrians, the event being commemorated by a monument in the public garden. The inhabitants, 18,000 in 1789, were reduced by the French Revolution to 10,000.

TOURMALINE, a mineral of much interest to the physicist on account of its optical and electrical properties; it is also of some geological importance as a rock-constituent (see SCHORL), whilst certain transparent varieties have economic value as gem-stones. The name is probably a corruption of *turmali*, or *toramalli*, the native name applied to tourmaline and zircon in Ceylon, whence specimens of the former mineral were brought to Europe by the Dutch in 1703. The green tourmaline of Brazil had, however, been known here much earlier; and coarse varieties of the mineral had passed for centuries under the German name of *Schörl*, an old mining word of uncertain origin, possibly connected with the old German *Schor* (refuse), in allusion to the occurrence of the mineral with the waste of the tin-mines. The German village of Schorlau may have taken its name from the mineral. It has been suggested that the Swedish form *skörl* has possible connexion with the word *skör*, brittle.

Tourmaline crystallizes in the rhombohedral division of the hexagonal system. The crystals have generally a prismatic habit, the prisms being longitudinally striated or even channelled. Trigonal prisms are characteristic, so that a transverse section becomes triangular or often nine-sided. By combination of several prisms the crystals may become sub-cylindrical. The crystals when doubly terminated are often hemimorphic or present dissimilar forms at the opposite ends; thus the hexagonal prisms in fig. 1 are terminated at one end by rhombohedral faces, *o*, P, and at the other by the basal plane *k'*. Doubly-terminated crystals, however, are comparatively rare; the crystals being usually attached at one end to the matrix. It is notable that prismatic crystals of tourmaline have in some cases been curved and fractured transversely; the displaced fragments having been cemented together

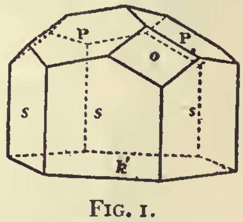

FIG. 1.

by deposition of fresh mineral matter. Tourmaline is not infrequently columnar, acicular or fibrous; and the fibres may radiate from a centre so as to form the so-called "tourmaline suns." Crystals of tourmaline present no distinct cleavage, but break with a sub-conchoidal fracture; and whilst the general lustre of the mineral is vitreous, that of the fractured surface is rather pitchy. The hardness is slightly above that of quartz (7). The specific gravity varies according to chemical composition, that of the colourless varieties being about 3, whilst in schorl it may rise to 3·2.

Tourmaline has a great range of colour, and in many cases the crystals are curiously parti-coloured. Occasionally, though rarely, the mineral is colourless, and is then known as achroite, a name proposed by R. Hermann in 1845, and derived from the Greek *ἄχροος* (uncoloured). Red tourmaline, which when of fine colour is the most valued of all varieties, is known as rubellite (*q.v.*). Green tourmaline is by no means uncommon, but the blue is rather rare and is distinguished by the name indigolite, generally written indicolite. Brown is a common colour, and black still more common, this being the usual colour of schorl, or common coarse tourmaline. Thin splinters of schorl may, however, be blue or brown by transmitted light.

The double refraction of tourmaline is strong. The mineral is optically negative, the ordinary index being about 1·64, and the extraordinary 1·62. Coloured tourmalines are intensely pleochroic, the ordinary ray, which vibrates perpendicular to the principal axis, being much more strongly absorbed than the extraordinary; hence a slice cut in the direction of the principal or optic axis transmits sensibly only the extraordinary ray, and may consequently be used as a polarizing medium. The brown tourmaline of Ceylon and Brazil is best adapted for this purpose, but the green is also used. Two plates properly mounted form the instrument used by opticians for testing spectacle-lenses, and are known as the "tourmaline tongs." In order to secure the best colour-effect when used as a gem-stone, the tourmaline should be cut with the table parallel to the optic axis.

It was in tourmaline that the phenomenon of pyroelectricity was first observed. On being heated in peat ashes its attractive power was observed by the Dutch, in the early part of the 18th century; and this curious character obtained for it the name of *aschtrekker*, or ash-drawer. J. R. Haüy first pointed out the relation of pyroelectricity with hemimorphism. Tourmaline is also piezoelectric, that is, it becomes electric by pressure. If a crystal be subjected to pressure along the optic axis, it behaves as though it were contracting by reduction of temperature. The mineral may also be rendered electric by friction, and retains the charge for a long time.

Tourmaline is a boro-silicate of singularly complex composition. Indeed the word tourmaline is sometimes regarded as the name of a group of isomorphous minerals rather than that of a definite species. Numerous analyses have been made, and the results discussed by a large number of authorities. In the view of S. L. Penfield and H. W. Foote all tourmaline may be derived from a boro-silicic acid of the formula $H_{20}B_2Si_4O_{21}$. It is believed that the hydrogen is present as hydroxyl, and that this may be partially replaced by fluorine. The tourmaline acid has probably the constitution $H_{18}(B{\cdot}OH)_2Si_4O_{19}$. Nine atoms of hydrogen are replaced by three of aluminium, and the remaining nine in part by other metals. Lithium is present in red tourmaline; magnesium dominates in brown; iron, manganese and sometimes chromium are found in green; and much iron occurs in the black varieties. Four groups are sometimes recognized, characterized by the presence of (1) lithium, (2) ferrous iron, (3) ferric iron and (4) magnesium.

Tourmaline occurs commonly in granite, greisen, gneiss and crystalline schists. In many cases it appears to have been formed by pneumatolysis, or the action on the rocks of heated vapours containing boron and fluorine, as in many tin-bearing districts, where tourmaline is a characteristic mineral. Near the margin of a mass of granite the rock often becomes schorlaceous or tourmaliniferous, and may pass into "tourmaline-rock," which is usually an aggregate of tourmaline and quartz. Tourmaline is an essential constituent of the west of England rocks called luxullianite (luxulyanite) and trowlesworthite. It occurs embedded in certain metamorphic limestones, where it is possibly due to fumarolic action. Microscopic crystals are common in clay-slate. By resistance to decomposition, tourmaline often survives the disintegration of the matrix, and thus passes into sands, clays, marls and other sedimentary deposits.

Many of the finest crystals of tourmaline occur in druses in granitic rocks, such as those of San Piero in Elba, where some of the pale pink and green prisms are tipped with black, and have consequently been called "nigger-heads." Lepidolite is a common associate of tourmaline, as at Rozena in Moravia. Tourmaline occurs, with corundum, in the dolomite of Campolongo, in canton Ticino, Switzerland. Fine black crystals, associated with apatite and quartz, were formerly found in granite at Chudleigh, near Bovey Tracey in Devonshire. The Russian localities for tourmaline are mentioned under RUBELLITE. Most of the tourmaline cut for jewelry comes from the gem-gravels of Ceylon. The green tourmaline has generally a yellowish or olive-green colour, and is known as "Ceylon chrysolite." Fine green crystals are found in Brazil, notably in the topaz-locality of Minas Novas; and when of vivid colour they have been called "Brazilian emeralds." Green tourmaline is a favourite ecclesiastical stone in South America Blue tourmaline occurs with the green; this variety is found also at Utö in Sweden (its original locality) and notably near Hazaribagh in Bengal. Certain kinds of mica occasionally contain flat crystals of tourmaline between the cleavage-planes.

Many localities in the United States are famous for tourmaline. Magnificent specimens have been obtained from Mt Mica, near Paris, Maine, where the mineral was accidentally discovered in 1820 by two students, E. L. Hamlin and E. Holmes. It occurs in granite, with lepidolite, smoky quartz, spodumene, &c.; and some of the prismatic crystals are notable for being red at one end and green at the other. Mt Rubellite at Hebron, and Mt Apatite at Auburn, are other localities in Maine which have yielded fine tourmaline. At Chesterfield, Massachusetts, remarkable crystals occur, some of which show on transverse section a triangular nucleus of red tourmaline surrounded by a shell of green. Red and green tourmalines, with lepidolite and kunzite, are found in San Diego county, California. Fine coloured tourmalines occur at Haddam Neck, Connecticut; and excellent crystals of black tourmaline are well known from Pierrepont, New York, whilst remarkable brown crystals occur in limestone at Gouverneur in the same state. Canada is rich in tourmaline, notably at Burgess in Lanark county, Ontario, and at Grand Calumet Island in the Ottawa river. Heemskirk Mountain, Tasmania, and Kangaroo Island, South Australia, have yielded fine coloured tourmaline fit for jewelry. Madagascar is a well-known locality for black tourmaline in large crystals.

Many varieties of tourmaline have received distinctive names, some of which are noticed above. Dravite is G. Tschermak's name for a brown tourmaline, rich in magnesia but with little iron, occurring near Unter Drauburg in the Drave district in Carinthia. Taltalite was a name given by I. Domeyko to a mixture of tourmaline and copper ore from Taltal in Chile. The colourless Elba tourmaline was called apyrite by J. F. L. Hausmann, in allusion to its refractory behaviour before the blow-pipe; whilst a black iron-tourmaline from Norway was termed aphrazite by J. B. d'Andrada, in consequence of its intumescence when heated. (F. W. R.*)

TOURNAI (Flemish *Doornik*), a city of Belgium, in the province of Hainaut, situated on the Scheldt. Pop. (1904), 36,744. Although in the course of its long history it has undergone many sieges and was sacked at various epochs by the Vandals, Normans, French and Spaniards, it preserves many monuments of its ancient days. Among these is the cathedral of Notre-Dame, one of the finest and best preserved Romanesque and Gothic examples in Belgium (for plan, &c., see ARCHITECTURE: *Romanesque and Gothic in Belgium*). Its foundation dates from the year 1030, while the nave is Romanesque of the middle of the 12th century, with much pointed work. The transept was added in the 13th century. The first choir was burned down in 1213, but was rebuilt in 1242 at the same time as the transept, and is a superb specimen of pointed Gothic. There are five towers with spires, which give the outside an impressive appearance, and much has been done towards removing the squalid buildings that formerly concealed the cathedral. There are several old pictures of merit, and the shrine of St Eleuthère, the first bishop of Tournai in the 6th century, is a remarkable product of the silversmith's art. The belfry on the Grand Place was built in 1187, partly reconstructed in 1391 and finally restored and endowed with a steeple in 1852. The best view of the cathedral can be obtained from its gallery. The church of St Quentin in the same square as the belfry is almost as ancient as Notre-Dame, and the people of Tournai call it the "little cathedral." In the church of St Brice is the tomb of Childeric discovered in 1655. Among the relics were three hundred small golden models of bees. These were removed to Paris, and when Napoleon was crowned emperor a century and a half later he chose Childeric's bees for the decoration of his coronation mantle. In this manner the bee became associated with the Napoleonic legend just as the lilies were with the Bourbons. The Pont des Trous over the Scheldt, with towers at each end, was built in 1290, and among many other interesting buildings there are some old houses still in occupation which date back to the 13th century. On the Grand Place is the fine statue of Christine de Lalaing, princess d'Epinoy, who defended Tournai against Parma in 1581. Tournai carries on a large trade in carpets (called Brussels), bonnet shapes, corsets and fancy goods generally. With regard to the carpet manufactory, it is said locally to date from the time of the Crusades, and it is presumed that the Crusaders learnt the art from the Saracens.

The history of Tournai dates from the time of Julius Caesar, when it was called *civitas Nerviorum* or *castrum Turnacum*. In the reign of Augustus, Agrippa fixed the newly mixed colony of Suevi and Menapii at Tournai, which continued throughout the period of Roman occupation to be of importance. In the 5th century the Franks seized Tournai, and Merovaeus made it the capital of his dynasty. This it remained until the subdivision of the Frank monarchy among the sons of Clovis. When feudal possessions, instead of being purely personal, were vested in the families of the holder after the death of Charlemagne, Tournai was specially assigned to Baldwin of the Iron Arm by Charles

KNIGHTS JOUSTING WITH CRONELLS ON THEIR LANCES. French MS. early XIV Century. (Royal MS. 14 E. iii.)

KNIGHTS JOUSTING. From a French MS. of the latter half of the XV Century. (Cotton MS. Nero D. ix.)

ENGLISH KNIGHTS RIDING INTO THE LISTS. From the Great Tournament Roll of 1511; by permission of the College of Arms.

the Bald, whose daughter Judith he had abducted, on receiving the hereditary title of count of Flanders. During the Burgundian period it was the residence of Margaret of York, widow of Charles the Bold; and the pretender Perkin Warbeck, whom she championed, if not born there, was the reputed son of a Jew of Tournai. In the early 16th century Tournai was an English possession for a few years and Henry VIII. sold it to Francis I. It did not long remain French, for in 1521 the count of Nassau, Charles V.'s general, took it and added it to the Spanish provinces. During the whole of the middle ages Tournai was styled the "seigneurie de Tournaisis," and possessed a charter and special privileges of its own. Near Tournai was fought, on the 11th of May 1745, the famous battle of Fontenoy. (D. C. B.)

TOURNAMENT, or Tourney (Fr. *tournement*, *tournoi*, Med. Lat. *torneamentum*, from *tourner*, to turn), the name popularly given in the middle ages to a species of mock fight, so called owing to the rapid *turning* of the horses (Skeat). Of the several medieval definitions of the tournament given by Du Cange (*Glossarium, s.v.* "Tourneamentum"), the best is that of Roger of Hoveden, who described tournaments as "military exercises carried out, not in the spirit of hostility (*nullo interveniente odio*), but solely for practice and the display of prowess (*pro solo exercitio, atque ostentatione virium*)." Men who carry weapons have in all ages played at the game of war in time of peace. But the tournament, properly so called, does not appear in Europe before the 11th century, in spite of those elaborate fictions of Ruexner's *Thurnierbuch* which detail the tournament laws of Henry the Fowler. More than one chronicler records the violent death, in 1066, of a French baron named Geoffroi de Preulli, who, according to the testimony of his contemporaries, "invented tournaments." In England, at least, the tournament was counted a French fashion, Matthew Paris calling it *conflictus gallicus*.

By the 12th century the tournament had grown so popular in England that Henry II. found it necessary to forbid the sport which gathered in one place so many barons and knights in arms. In that age we have the famous description by William FitzStephen of the martial games of the Londoners in Smithfield. He tells how on Sundays in Lent a noble train of young men would take the field well mounted, rushing out of the city with spear and shield to ape the feats of war. Divided into parties, one body would retreat, while another pursued striving to unhorse them. The younger lads, he says, bore javelins disarmed of their steel, by which we may know that the weapon of the elders was the headed lance. William of Newbury tells us how the young knights, balked of their favourite sport by the royal mandate, would pass over sea to win glory in foreign lists. Richard I. relaxed his father's order, granting licences for tournaments, and Jocelin of Brakelond has a long story of the great company of cavaliers who held a tournament between Thetford and Bury St Edmunds in defiance of the abbot. From that time onward unlicensed tourneying was treated as an offence against the Crown, which exacted heavy fees from all taking part in them even when a licence had been obtained. Often the licence was withheld, as in 1255, when the king's son's grave peril in Gascony is alleged as a reason for forbidding a meeting. In 1299 life and limb were declared to be forfeit in the case of those who should arrange a tourney without the royal licence, and offenders were to be seized with horse and harness. As the tournament became an occasion for pageantry and feasting, new reason was given for restraint: a simple knight might beggar himself over a sport which risked costly horses and carried him far afield. Jousters travelled from land to land, like modern cricketers on their tours, offering and accepting challenges. Thus Edward I., before coming to the throne, led eighty knights to a tournament on the Continent. Before the jousts at Windsor on St George's Day in 1344 heralds published in France, Scotland, Burgundy, Hainault, Flanders, Brabant and the domains of the emperor the king's offer of safe conduct for competitors. At the weddings of princes and magnates and at the crowning of kings the knights gathered to the joustings, which had become as much a part of such high ceremonies as the banquet and the minstrelsy. The fabled glories of the Round Table were revived by princely hosts, who would assemble a gallant company to keep open house and hold the field against all comers, as did Mortimer, the queen's lover, when, on the eve of his fall, he brought all the chivalry of the land to the place where he held his Round Table. About 1292 the "Statute of Arms for Tournaments" laid down, "at the request of the earls and barons and of the knighthood of England," new laws for the game. Swords with points were not to be used, nor pointed daggers, nor club nor mace. None was to raise up a fallen knight but his own appointed squires, clad in his device. The squire who offended was to lose horse and arms and lie three years in gaol. A northern football crowd would understand the rule that forbade those coming to see the tournament to wear harness or arm themselves with weapons. Disputes were to be settled by a court of honour of princes and earls. That such rules were needful had been shown at Rochester in 1251, where the foreign knights were beaten by the English and so roughly handled that they fled to the city for refuge. On their way the strangers were faced by another company of knights who handled them roughly and spoiled them, thrashing them with staves in revenge for the doings at a Brackley tournament. Even as early as the 13th century some of these tournaments were mere pageants of horsemen. For the Jousts of Peace held at Windsor Park in 1278 the sword-blades are of whalebone and parchment, silvered; the helms are of boiled leather and the shields of light timber. But the game could make rough sport. Many a tournament had its tale of killed and wounded in the chronicle books. We read how Roger of Lemburn struck Arnold de Montigny dead with a lance thrust under the helm. The first of the Montagu earls of Salisbury died of hurts taken at a Windsor jousting, and in those same lists at Windsor the earl's grandson Sir William Montagu was killed by his own father. William Longespee in 1256 was so bruised that he never recovered his strength, and he is among many of whom the like is written. Blunted or "rebated" lance-points came early into use, and by the 14th century the coronall or cronell head was often fitted in place of the point. After 1400 the armourers began to devise harness with defences specially wrought for service in the lists. But the joust lost its chief perils with the invention of the tilt, which, as its name imports, was at first a cloth stretched along the length of the lists. The cloth became a stout barrier of timber, and in the early 16th century the knight ran his course at little risk. Locked up in steel harness, reinforced with the grand-guard and the other jousting pieces, he charged along one side of this barrier, seeing little more through the pierced sight-holes of the helm than the head and shoulders of his adversary. His bridle arm was on the tilt-side, and thus the blunted lance struck at an angle upon the polished plates. Mishaps might befall. Henry II. of France died from the stroke of Gabriel de Montgomeri, who failed to cast up in time the truncheon of his splintered lance. But the 16th-century tournament was, in the main, a bloodless meeting.

The 15th century had seen the mingling of the tournament and the pageant. Adventurous knights would travel far afield in time of peace to gain worship in conflicts that perilled life and limb, as when the Bastard of Burgundy met the Lord Scales in 1466 in West Smithfield under the fair and costly galleries crowded with English dames. On the first day the two ran courses with sharp spears; on the second day they tourneyed on horseback, sword in hand; on the third day they met on foot with heavy pole-axes. But the great tournament held in the market-place of Bruges, when the jousting of the Knights of the Fleece was part of the pageant of the Golden Tree, the Giant and the Dwarf, may stand as a magnificent example of many such gay gatherings. When Henry VIII. was scattering his father's treasure the pageant had become an elaborate masque. For two days after the crowning of the king at Westminster, Henry and his queen viewed from the galleries of a fantastic palace set up beside the tilt-yard a play in which deer were pulled down by greyhounds in a paled park, in which the Lady Diana and the Lady Pallas came forward, embowered in moving castles, to present the champions. Such costly shows fell out of fashion after the death of Henry VIII.; and in England the tournament remained, until the end, a martial sport. Sir Henry Lee rode as Queen Elizabeth's champion in the tilt-yard of Whitehall until his years forced him to surrender the gallant office to that earl of Cumberland who wore the Queen's glove pinned to the flap of his hat. But in France the tournament lingered on until it degenerated to the carrousel, which, originally a horseman's game in which cavaliers pelted each other with balls, became an unmartial display when the French king and his courtiers pranced in such array as the wardrobe-master of the court ballets would devise for the lords of Ind and Africk.

The tournament was, from the first, held to be a sport for men of noble birth, and on the Continent, where nobility was more exactly defined than in England, the lists were jealously closed to all combatants but those of the privileged class. In the German lands, questions as to the purity of the strain of a candidate for admission to a noble chapter are often settled by appeal to the fact that this or that ancestor had taken part in a tournament. Konrad Grünenberg's famous heraldic manuscript shows us the *Helmschau* that came before the German tournament of the 15th century—the squires carrying each his master's crested helm, and a little scutcheon of arms hanging from it, to the hall where the king of arms stands among the ladies and, wand in hand, judges each blazon. In England several of those few rolls of arms which have come down to us from the middle ages record the shields displayed at certain tournaments. Among the illustrations of the article HERALDRY will be seen a leaf of a roll of arms of French and English jousters at the Field of the Cloth of Gold, and this leaf is remarkable as illustrating also the system of "checques" for noting the points scored by the champions. (O. BA.)

TOURNEFORT, JOSEPH PITTON DE (1656–1708), French botanist, was born at Aix, in Provence, on the 5th of June 1656. He studied in the convent of the Jesuits at Aix, and was destined for the Church, but the death of his father left him free to follow his botanical inclinations. After two years' collecting, he studied medicine at Montpellier, but was appointed professor of botany at the Jardin des Plantes in 1683. By the king's order he travelled through western Europe, where he made extensive collections, and subsequently spent three years in Greece and Asia Minor (1700–1702). Of this journey a description in a series of letters was posthumously published in 3 vols. (*Relation d'un voyage du Levant*, Lyons, 1717). His principal work is entitled *Institutiones rei herbariae* (3 vols. Paris, 1700), and upon this rests chiefly his claims to remembrance as one of the most eminent of the systematic botanists who prepared the way for Linnaeus. He died on the 28th of December 1708.

TOURNEUR, CYRIL (*c.* 1575–1626), English dramatist, was perhaps the son of Captain Richard Turner, water-bailiff and subsequently lieutenant-governor of Brill in the Netherlands. Cyril Tourneur also served in the Low Countries, for in 1613 there is a record made of payment to him for carrying letters to Brussels. He enjoyed a pension from the government of the United Provinces, possibly by way of compensation for a post held before Brill was handed over to the Dutch in 1616. In 1625 he was appointed by Sir Edward Cecil, whose father had been a former governor of Brill, to be secretary to the council of war. This appointment was cancelled by Buckingham, but Tourneur sailed in Cecil's company to Cadiz. On the return voyage from the disastrous expedition he was put ashore at Kinsale with other sick men, and died in Ireland on the 28th of February 1626. (M. BR.)

An allegorical poem, worthless as art and incomprehensible as allegory, is his earliest extant work; an elegy on the death of Prince Henry, son of James I., is the latest. The two plays on which his fame rests, and on which it will rest for ever, were published respectively in 1607 and 1611, but all students have agreed to accept the internal evidence which assures us that the later in date of publication must be the earlier in date of composition. His only other known work is an epicede on Sir Francis Vere, of no great merit as poetry, but of some value as conveying in a straightforward and masculine style the poet's ideal conception of a perfect knight or "happy warrior," comparable by those who may think fit to compare it with the more nobly realized ideals of Chaucer and of Wordsworth. But if Tourneur had left on record no more memorable evidence of his powers than might be supplied by the survival of his elegies, he could certainly have claimed no higher place among English writers than is now occupied by the Rev. Charles Fitzgeoffrey, whose voluminous and fervent elegy on Sir Francis Drake is indeed of more actual value, historic or poetic, than either or than both of Tourneur's elegiac rhapsodies. The singular power, the singular originality and the singular limitation of his genius are all equally obvious in *The Atheist's Tragedy*, a dramatic poem no less crude and puerile and violent in action and evolution than simple and noble and natural in expression and in style. The executive faculty of the author is in the metrical parts of his first play so imperfect as to suggest either incompetence or perversity in the workman; in *The Revenger's Tragedy* it is so magnificent, so simple, impeccable and sublime that the finest passages of this play can be compared only with the noblest examples of tragic dialogue or monologue now extant in English or in Greek. There is no trace of imitation or derivation from an alien source in the genius of this poet. The first editor of Webster has observed how often he imitates Shakespeare; and, in fact, essentially and radically independent as is Webster's genius also, the sovereign influence of his master may be traced not only in the general tone of his style, the general scheme of his composition, but now and then in a direct and never an unworthy or imperfect echo of Shakespeare's very phrase and accent. But the resemblance between the tragic verse of Tourneur and the tragic verse of Shakespeare is simply such as proves the natural affinity between two great dramatic poets, whose inspiration partakes now and then of the quality more proper to epic or to lyric poetry. The fiery impulse, the rolling music, the vivid illustration of thought by jets of insuppressible passion, the perpetual sustenance of passion by the implacable persistency of thought, which we recognise as the dominant and distinctive qualities of such poetry as finds vent in the utterances of Hamlet or of Timon, we recognise also in the scarcely less magnificent poetry, the scarcely less fiery sarcasm, with which Tourneur has informed the part of Vindice—a harder-headed Hamlet, a saner and more practically savage and serious Timon. He was a satirist as passionate as Juvenal or Swift, but with a finer faith in goodness, a purer hope in its ultimate security of triumph. This fervent constancy of spirit relieves the lurid gloom and widens the limited range of a tragic imagination which otherwise might be felt as oppressive rather than inspiriting. His grim and trenchant humour is as peculiar in its sardonic passion as his eloquence is original in the strenuous music of its cadences, in the roll of its rhythmic thunder. As a playwright, his method was almost crude and rude in the headlong straightforwardness of its energetic simplicity; as an artist in character, his interest was intense but narrow, his power magnificent but confined; as a dramatic poet, the force of his genius is great enough to ensure him an enduring place among the foremost of the followers of Shakespeare. (A. C. S.)

BIBLIOGRAPHY.—The complete list of his extant works runs: *The Atheists Tragedie; or, The Honest Man's Revenge* (1611); *A Funerall Poeme Upon the Death of the Most Worthie and True Soldier, Sir Francis Vere, Knight* . . . (1609); "A Griefe on the Death of Prince Henrie, Expressed in a Broken Elegie . . .," printed with two other poems by John Webster and Thomas Haywood as *Three Elegies on the most lamented Death of Prince Henry* (1613); *The Revengers Tragaedie* (1607 and 1608); and an obscure satire, *The Transformed Metamorphosis* (1600). The only other play of Tourneur's of which we have any record is *The Nobleman*, the MS. of which was destroyed by John Warburton's cook. This was entered on the Stationers' Register (Feb. 15, 1612) as a "Tragecomedye called The Nobleman written by Cyrill Tourneur." In 1613 a letter from Robert Daborne to Henslowe states that he has commissioned Cyril Tourneur to write one act of the promised *Arraignment of*

London. "The Character of Robert, earl of Salisburye, Lord High Treasurer of England . . . written by Mr Sevill Turneur . . .," in a MS in possession of Lord Mostyn (Hist. MSS. Commission, 4th Report, appendix, p. 361) may reasonably be assigned to Tourneur. Although no external evidence is forthcoming, Mr R. Boyle names Tourneur as the collaborator of Massinger in *The Second Maid's Tragedy* (licensed 1611).

The Revenger's Tragedy was printed in Dodsley's *Old Plays* (vol. iv., 1744, 1780 and 1825), and in *Ancient British Drama* (1810, vol. ii.). The best edition of Tourneur's works is *The Plays and Poems of Cyril Tourneur, edited with Critical Introduction and Notes*, by J. Churton Collins (1878). See also the two plays printed with the masterpieces of Webster, with an introduction by J A. Symonds, in the " Mermaid Series " (1888 and 1903). No particulars of Tourneur's life were available until the facts given above were abstracted by Mr Gordon Goodwin from the *Calendar of State Papers* (" Domestic Series," 1628–1629, 1629–1631, 1631–1633) and printed in the *Academy* (May 9, 1891). A critical study of the relation of *The Atheist's Tragedy* to *Hamlet* and other revenge-plays is given in Professor A. H. Thorndike's " Hamlet and Contemporary Revenge Plays " (*Publ. of the Mod. Lang. Assoc.*, Baltimore, 1902). For the influence of Marston on Tourneur see E. E. Stoll, *John Webster* . . . (1905, Boston, Massachusetts); pp. 105–116. (M. Br.)

TOURNEUX, JEAN MAURICE (1849–), French man of letters and bibliographer, son of the artist and author J. F. E. Tourneux, was born in Paris on the 12th of July 1849. He began his career as a bibliographer by collaborating in new editions of the *Supercheries littéraires* of Joseph Quérard and the *Dictionnaire des anonymes* of Antoine Barbier. His most important bibliographical work was the *Bibliographie de l'histoire de Paris pendant la révolution française* (3 vols. 1890–1901), which was crowned by the Academy of Inscriptions. This valuable work serves as a guide for the history of the city beyond the limits of the Revolution.

His other works include bibliographies of Prosper Mérimée (1876), of Théophile Gautier (1876), of the brothers de Goncourt (1897) and others; also editions of F. M. Grimm's *Correspondance littéraire*, of Diderot's *Neveu de Rameau* (1884), of Montesquieu's *Lettres persanes* (1886), &c.

TOURNON, a town of south-western France, capital of an arrondissement in the department of Ardèche, on the right bank of the Rhone, 58 m. S. of Lyons by rail. Pop. (1906), town, 3642; commune, 5003. Tournon preserves a gateway of the 15th century and other remains of fortifications and an old castle used as town hall, court-house and prison and containing a Gothic chapel. The church of St Julian dates chiefly from the 14th century. The lycée occupies an old college founded in the 16th century by Cardinal François de Tournon. Of the two suspension bridges which unite the town with Tain on the left bank of the river, one was built in 1825 and is the oldest in France. A statue to General Rampon (d. 1843) stands in the Place Carnot. Wood-sawing, silk-spinning, and the manufacture of chemical manures, silk goods and hosiery are carried on in the town, which has trade in the wine of the Rhone hills. Tournon had its own counts as early as the reign of Louis I. In the middle of the 17th century the title passed from them to the dukes of Ventadour.

TOURNUS, a town of east-central France, in the department of Saône-et-Loire, on the right bank of the Saône, 20 m. N. by E. of Mâcon on the Paris-Lyons railway. Pop. (1906), 3787. The church of St Philibert (early 11th century) once belonging to the Benedictine abbey of Tournus, suppressed in 1785, is in the Burgundian Romanesque style. The façade lacks one of the two flanking towers originally designed for it. The nave is roofed with barrel vaulting, supported on tall cylindrical columns. The choir beneath which is a crypt of the 11th century has a deambulatory and square chapels. In the Place de l'Hôtel de Ville stands a statue of J. B. Greuze, born in the town in 1725. There are vineyards in the surrounding district and the town and its port have considerable commerce in wine and in stone from the neighbouring quarries. Chair-making is an important industry.

TOURS, a town of central France, capital of the department of Indre-et-Loire, 145 m. S.W. of Paris by rail. Pop. (1906), town 61,507; commune, 67,601. Tours lies on the left bank of the Loire on a flat tongue of land between that river and the Cher a little above their junction. The right bank of the Loire is bordered by hills at the foot of which lie the suburbs of St Cyr and St Symphorien. The river is crossed by two suspension bridges, partly built on islands in the river, and by a stone bridge of the second half of the 18th century, the Pont de Tours. Many foreigners, especially English, live at or visit Tours, attracted by the town itself, its mild climate and situation in "the garden of France," and the historic châteaux in the vicinity. The Boulevard Béranger, with its continuation, the Boulevard Heurteloup, traverses Tours from west to east dividing it into two parts; the old town to the north, with its narrow streets and ancient houses, contains the principal buildings, the shops and the business houses, while the new town to the south, centring round a fine public garden, is almost entirely residential. The Rue Nationale, the widest and handsomest street in Tours, is a prolongation of the Pont de Tours and runs at right angles to the boulevards, continuing under the name of the Avenue de Grammont until it reaches the Cher.

St Gatien, the cathedral of Tours, though hardly among the greatest churches of France, is nevertheless of considerable interest. A cathedral of the first half of the 12th century was burnt in 1166 during the quarrel between Louis VII. of France and Henry II. of England. A new cathedral was begun about 1170 but not finished till 1547. The lower portions of the west towers belong to the 12th century, the choir to the 13th century; the transept and east bays of the nave to the 14th; the remaining bays, a cloister on the north, and the façade, profusely decorated in the Flamboyant style, to the 15th and 16th centuries, the upper part of the towers being in the Renaissance style of the 16th century. In the interior there is fine stained glass, that of the choir (13th century) being especially remarkable. The tomb of the children of Charles VIII., constructed in the first years of the 16th century and attributed to the brothers Juste is also of artistic interest.

An example of Romanesque architecture survives in the great square tower of the church of St Julien, the rest of which is in the early Gothic style of the 13th century, with the exception of two apses added in the 16th century. Two towers and a Renaissance cloister are the chief remains of the celebrated basilica of St Martin built mainly during the 12th and 13th centuries and demolished in 1802. It stood on the site of an earlier and very famous church built from 466 to 472 by bishop St Perpetuus and destroyed together with many other churches in a fire in 998. Two other churches worthy of mention are Notre-Dame la Riche, originally built in the 13th century, rebuilt in the 16th, and magnificently restored in the 19th century; and St Saturnin of the 15th century. The new basilica of St Martin and the church of St Étienne are modern. Of the old houses of Tours the hôtel Gouin and that wrongly known as the house of Tristan l'Hermite (both of the 15th century) are the best known. Tours has several learned societies and a valuable library, including among its MSS. a gospel of the 8th century on which the kings of France took oath as honorary canons of the church of St Martin. The museum contains a collection of pictures, and the museum of the Archaeological Society of Touraine has valuable antiquities; there is also a natural history museum.

The chief public monuments are the fountain of the Renaissance built by Jacques de Beaune (d. 1527), financial minister, the statues of Descartes, Rabelais and Balzac, the latter born at Tours, and a monument to the three doctors Bretonneau, Trousseau and Velpeau. Tours is the seat of an archbishop, a prefect, and a court of assizes, and headquarters of the IX. Army Corps and has tribunals of first instance and of commerce, a board of trade arbitration, a chamber of commerce and a branch of the Bank of France. Among its educational institutions are a preparatory school of medicine and pharmacy, lycées for both sexes, a training college for girls and schools of fine art and music. The industrial establishments of the town include silk factories and numerous important printing-works, steel works, iron foundries and factories for automobiles, machinery, oil, lime and cement, biscuits, portable buildings, stained glass, boots and shoes and porcelain. A considerable trade is carried on in the wine of the district and in brandy and in dried fruits, sausages and confectionery, for which the town is well known. Three-quarters of a mile to the south-west of Tours lie unimportant remains of Plessis-les-Tours, the chateau built by Louis XI., whither he retired before his death in 1483. On the right bank of the Loire 2 m. above the town are the ruins of the ancient and powerful abbey of Marmoutier. Five miles to the north-west is the large agricultural reformatory of Mettray founded in 1839.

Tours (see Touraine), under the Gauls the capital of the Turones or Turons, originally stood on the right bank of the Loire, a little above the present village of St Symphorien. At first called *Altionos*, the town was afterwards known as *Caesarodunum*. The Romans removed the town from the hill where it originally stood to the plain on the left bank of the river. Behind the present cathedral, remains of the amphitheatre (443 ft. in length by 394 in breadth) built towards the end of the 2nd century might formerly be seen. Tours became Christian about 250 through the preaching of Gatien, who founded the bishopric. The first cathedral was built a hundred years later by St Litorius. The bishopric became an archbishopric when Gratian made Tours the capital of Lugdunensis Tertia though the bishops did not adopt the title of archbishop till the 9th century. About the beginning of the 5th century the official name of Caesarodunum was changed for that of *Civitas Turonorum*. St Martin, the great apostle of the Gauls, was bishop of Tours in the 4th century, and he was buried in a suburb which soon became as important as the town itself from the number of pilgrims who flocked to his tomb. Towards the end of the 4th century, apprehensive of barbarian invasion, the inhabitants pulled down some of their earlier buildings in order to raise a fortified wall, the course of which can still be traced in places. Their advanced fort of Larcay still overlooks the valley of the Cher. Affiliated to the Armorican confederation in 435, the town did not fall to the Visigoths till 473, and the new masters were always hated. It became part of the Frankish dominions under Clovis, who, in consideration of the help afforded by St Martin, presented the church with rich gifts out of the spoils taken from Alaric, confirmed and extended its right of sanctuary, and accepted for himself and his successors the title of canon of St Martin. At the end of the 6th century the bishopric was held by St Gregory of Tours. Tours grew rapidly in prosperity under the Merovingians, but abuse of the right of sanctuary led to great disorder, and the church itself became a hotbed of crime. Charlemagne re-established discipline in the disorganized monastery and set over it the learned Alcuin, who established at Tours one of the oldest public schools of Christian philosophy and theology. The arts flourished at Tours in the middle ages and the town was the centre of the Poitevin Romanesque school of architecture. The abbey was made into a collegiate church in the 11th century, and was for a time affiliated to Cluny, but soon came under the direct rule of Rome, and for long had bishops of its own. The suburb in which the monastery was situated became as important as Tours itself under the name of Martinopolis. The Normans, attracted by its riches, pillaged it in 853 and 903. Strong walls were erected from 906 to 910, and the name was changed to that of Châteauneuf. Philip Augustus sanctioned the communal privileges which the inhabitants forced from the canons of St Martin and the innumerable offerings of princes, lords and pilgrims maintained the prosperity of the town all through the middle ages. A 13th-century writer speaks with enthusiasm of the wealth and luxury of the inhabitants of Châteauneuf, of the beauty and chastity of the women and of the rich shrine of the saint. In the 14th century Tours was united to Châteauneuf within a common wall, of which a round tower, the Tour de Guise, remains, and both towns were put under the same administration. The numerous and long-continued visits of Charles VII., Louis XI., who established the silk-industry, and Charles VIII. during the 15th century favoured the commerce and industry of the town, then peopled by 75,000 inhabitants. In the 15th and 16th centuries the presence of Jean Fouquet the painter of Michel Colomb and the brothers Juste the sculptors, enhanced the fame of the town in the sphere of art. In 1562 Tours suffered from the violence of both Protestants and Catholics, and enjoyed no real security till after the pact entered into at Plessis-lès-Tours between Henry III. and Henry of Navarre in 1589. In the 17th and 18th centuries Tours was the capital of the government of Touraine. Its manufactures, of which silk weaving was the chief, suffered from the revocation of the Edict of Nantes (1685). In 1772 its mint, whence were issued the "livres" of Tours (*librae Turonenses*) was suppressed. During the Revolution the town formed a base of operations of the Republicans against the Vendeans. In 1870 it was for a time the seat of the delegation of the government of national defence. In 1871 it was occupied by the Germans from the 10th of January to the 8th of March.

See P. Vitry, *Tours et les châteaux de Touraine* (Paris, 1905); E. Giraudet, *Histoire de la ville de Tours* (Tours, 1873); *Les Artistes tourangeaux* (Tours, 1885).

TOURVILLE, ANNE-HILARION DE COTENTIN (or COSTANTIN), COMTE DE (1642–1701), French admiral and marshal of France, was the son of César de Cotentin, or Costantin, who held offices in the household of the king and of the prince of Condé. He is said to have been born at Tourville in Normandy, but was baptized in Paris on the 24th of November 1642, was commonly known as M. de Tourville, and was destined by his family to enter the Order of Malta. From the age of fourteen to the age of twenty-five, he served with the galleys of the Order. At that time the knights were still fighting the Barbary pirates of Algiers and Tunis. The young Anne-Hilarion is said to have been distinguished for courage. His life during these years, however, is little known. The supposed *Memoirs* bearing his name were published by the Abbé de Magron in the 18th century and belong to the large class of historical romances which professed to be biographies or autobiographies. In 1667 he was back in France, and was incorporated in the corps of officers of the French Royal navy which Louis XIV. was then raising from the prostration into which it had fallen during his minority. The positions of French naval officer and knight of Malta were not incompatible. Many men held both. The usual practice was that they did not take the full vows till they were in middle life, and had reached the age when they were entitled to hold one of the great offices. Until then they were free to marry, on condition of renouncing all claim to the chief places. As Anne-Hilarion de Cotentin married a wealthy widow, the marquise de Popelinière, in 1689 at which time he was made count of Tourville, he severed his connexion with the Order. Nor does he appear to have served with it at all after his return to France in 1667. He was at first employed in cruising against the Barbary pirates and the Turks. In the expedition sent against Crete in 1668–69 under command of the Duc de Beaufort he had command of the "Croissant" (44). The Duc de Beaufort was killed, and the expedition was a failure. When the war with Holland in which France and England acted as allies began in 1670, Tourville commanded the "Page" (50), in the squadron of the comte d'Estrées (1624–1707) sent to co-operate with the duke of York. He was present at the battle of Solebay (June 7, 1672), and in the action on the coast of Holland in the following year, when Prince Rupert commanded the English fleet. When England withdrew from the alliance, the scene of the naval war was transferred to the Mediterranean, where Holland was co-operating with the Spaniards. Tourvillle served under Abraham Duquesne in his battles with De Ruyter. He particularly distinguished himself at the battle of Palermo on the 2nd of June 1676. By this time he was known as one of the best officers in the service of King Louis XIV. Unlike many employed by the king to command his ships in the earlier part of his reign, Tourville was a seaman. He had the reputation of being able to do all the work required in a ship, and he had made a study of naval warfare. The great treatise on naval tactics afterwards published under the name of his secretary, the Jesuit Hoste or l'Hoste, was understood to have been inspired by him. In 1683 he was chef d'escadre—rear admiral—with Duquesne in operations against the Barbary pirates, and he continued on that service with D'Estrées. By 1689 he had been promoted lieutenant-général des armées navales, and was named vice-admiral du Levant or of the East. In June of that year he took up the commandership-in-chief of the French naval forces in the war against England and her continental allies which had begun in the previous year. From this time till the failure of his resources compelled King Louis XIV. to withdraw his fleets from the sea, Tourville continued to command the naval war in the Channel and the Atlantic. His conduct and example during this period were the source of the system of manœuvring to gain an advantage by some method other than plain fighting. The personal character of Tourville must be held to account largely for the timidity of the principles he established. Tourville's personal valour was of the finest quality, but like many other brave men, he was nervous under the weight of responsibility. It is no less clear that anxiety to avoid risking a disaster to his reputation was of more weight with him than the wish to win a signal success. He belonged to the type of men in whose minds the evil which may happen is always more visible than the good. In 1690 he had an opportunity which might well have tempted the most cautious, and he missed it out of sheer care to keep his fleet safe against all conceivable chances, aided perhaps by a pedantic taste for formal, orderly movement. He was opposed in the channel by the allies, who had only fifty-six ships, while his own force, though it included some vessels of no serious value, was from seventy to eighty sail strong. He was feebly attacked by Admiral Arthur Herbert, the newly created earl of Torrington, off Beachy Head on the 10th of July. The Dutch ships in the van were surrounded. The allies had to retreat in disorder, and Tourville followed in "line of battle" which limited his speed to that of his slowest ship. So his enemy escaped with comparatively little loss. In the following year he performed his famous "off shore cruise," in the Bay of Biscay. He moved to and fro in fine order avoiding being brought to battle, but also failing to inflict any harm on his opponent. In the meantime the cause of King James II. was ruined in Ireland. In 1692 the Mediterranean fleet having failed to join him, he was faced by a vastly superior force of the allies. The French king had prepared a military force to invade England, and Tourville was expected to prepare the way. Having at least a clear indication that he was expected to act with vigour, if not precise orders to fight against any odds, he made a resolute attack on the centre of the allies on the 29th of May off Cape Barfleur, and drew off before he was surrounded. This action which with the pursuit of the following days made up what is called the battle of La Hogue, from the Bay where some of the fugitive French ships were destroyed, or Barfleur, proved his readiness to face danger. But his inability to take and act on a painful decision was no less proved in the retreat. He hesitated to sacrifice his crippled flagship, and thereby detained his whole fleet. The result was that the "Soleil Royale" herself and fifteen other ships were cut off and destroyed at La Hogue. In 1693 he was again at sea with a great fleet, and had a chance to inflict extreme injury on the allies by the capture of the Smyrna convoy which included their whole Mediterranean trade for the year. He did it a great deal of harm outside the Straits of Gibraltar, but again he kept his fleet in battle order, and a large part of the convoy escaped. King Louis XIV. who had a strong personal regard for him, continued to treat him with favour. Tourville was made Marshal of France in 1693, but the growing exhaustion of the French treasury no longer allowed the maintenance of great fleets at sea. Tourville remained generally at Toulon, and had no more fighting. He died in Paris in 1701. His only son, a colonel in the army, was killed at Denain in 1712.

The English account of the battles of Beachy Head and La Hogue will be found in Ledyard's Naval History. Troude's *Batailles navales de la France* gives the French version of these and the other actions in which Tourville was concerned. Tourville is frequently mentioned in the *Life of Duquesne* by M. Jal. (D. H.)

TOUSSAINT L'OUVERTURE (or Louverture), **PIERRE-DOMINIQUE** (*c.* 1746–1803), one of the liberators of Haiti, claimed to be descended from an African chief, his father, a slave in Haiti, being the chief's second son. He was at first surnamed Breda, but this was afterwards changed to L'Ouverture in token of the results of his valour in causing a gap in the ranks of the enemy. From childhood he manifested unusual abilities and succeeded, by making the utmost use of every opportunity, in obtaining a remarkably good education. He obtained the special confidence of his master, and was made superintendent of the other negroes on the plantation. After the insurrection of 1791 he joined the insurgents, and, having acquired some knowledge of surgery and medicine, acted as physician to the forces. His rapid rise in influence aroused, however, the jealousy of Jean François, who caused his arrest on the ground of his partiality to the whites. He was liberated by the rival insurgent chief Baisson, and a partisan war ensued, but after the death of Baisson he placed himself under the orders of Jean François. Subsequently he joined the Spaniards, but, when the French government ratified the act declaring the freedom of the slaves, he came to the aid of the French. In 1796 he was named commander-in-chief of the armies of St Domingo, but, having raised and disciplined a powerful army of blacks, he made himself master of the whole country, renounced the authority of France, and announced himself "the Buonaparte of St Domingo." He was taken prisoner by treachery on the part of France, and died in the prison of Joux, near Besançon, on the 27th of April 1803.

See Toussaint l'Ouverture's own *Mémoires*, with a life by Saint Remy; (Paris, 1850); Gragnon-Laconte, *Toussaint Louverture* (Paris, 1887); Schölcher, *Vie de Toussaint Louverture* (Paris, 1889); and J. R. Beard, *Life of Toussaint Louverture* (1853).

TOW, the term given in textile manufacture to the short fibres formed during the processes of scutching and hackling, and also to the yarns which are made from these fibres. A special machine termed a carding engine or a tow card is used to form these fibres into a sliver, this sliver then passes to the drawing frames, and thereafter follows the same process as line yarns in flax spinning.

TOWANDA, a borough and the county-seat of Bradford county, Pennsylvania, U.S.A., on the west bank of the Susquehanna river, about 50 m. N.W. of Wilkes-Barré. Pop. (1890), 4169; (1900), 4663 (322 foreign-born); (1910) 4281. Towanda is served by the Lehigh Valley and the Susquehanna & New York railways. It is situated about 730 ft. above the sea, and is surrounded by high hills. Towanda contains the museum of the Bradford County Historical Society. The borough is in a farming, dairying and stock-raising region, and has various manufactures. The first settlement was made by William Means in 1786, the village was laid out in 1812, became the county-seat in the same year, was variously known for some years as Meansville, Overton, Williamson, Monmouth and Towanda, and in 1828 was incorporated as the borough of Towanda. Its name is an Indian word said to mean "where we bury the dead."

TOWCESTER, a market town in the southern parliamentary division of Northamptonshire, England, 8 m. S.S.W. of Northampton, on the East & West Junction and the Northampton & Banbury Junction railways. Pop. (1901), 2371. It is pleasantly situated on the small river Tove, a left-bank affluent of the Ouse. The church of St Lawrence is a good Early English, Decorated and Perpendicular building, with a fine western Perpendicular tower. There are a considerable agricultural trade and a manufacture of boots and shoes.

Here was a Roman town or village situated on Watling Street. The site has yielded a considerable number of relics. In the 10th century a fortress was maintained here against the invading Danes. The site of both this and the Roman station is marked by an artificial mound known as Burg Hill, not far from the church, above the river. Towcester, with the whole of this district, witnessed a large part of the operations during the Civil War of the 17th century.

TOWEL, a cloth used for the purpose of drying the hands, face or body after bathing or washing. These cloths are made of different materials, known as "towellings," the two principal kinds are "huckaback," a slightly roughened material for chamber towels for face and hands, and Turkish towelling, with a much rougher surface, for bath towels; finer towellings are made of linen or damask. The term has a particular ecclesiastical usage as applied to a linen altar-cloth or to a rich cloth of embroidered silk, velvet, &c., covering the altar at all "such periods when Mass is not being celebrated."

The Mid. Eng. *towaille* comes through the O. Fr. *touaille* from the Low Lat. *toacula*, represented in other Romanic languages by Sp. *toalla*, Ital. *tovaglia*; this is to be referred to the Teutonic verb meaning "to wash," O. H. G. *twahan*, M. H. G. *dwahen*, O. Eng. *þweán*, and cf. Ger. *Zwehle*, provincial Eng. *dwile*, a dish-cloth.

TOWER (Lat. *turris*; Fr. *tour*, *clocher*; Ital. *torre*; Ger. *Thurm*), the term given to a lofty building originally designed for defence, and, as such, attached to and forming part of the fortifications of a city or castle. Towers do not seem to have existed in Egypt, but in Mesopotamia from the earliest times they form the most important feature in the city walls, and are shown in the bas-reliefs of the Assyrian palaces at Nimroud and elsewhere. The earliest representation is perhaps that engraved on the tablet in the lap of Gudea the priest king of Lagash (2700 B.C.), whose statue, found at Tello, is now in the Louvre; the drawing is that of a large fortified enclosure, with gates, bastions and towers, corresponding with remains of similar structures of the same and later periods. In the discoveries made here, at Susa and at Dom Sargoukin, the towers were about 40 ft. square, projecting from 16 to 20 ft. in front of the curtain walls which connected them, and standing about 80 ft. apart. In Roman and Byzantine times this distance was increased, owing probably to the greater speed of projectiles, and in the wall built by Theodosius at Constantinople the towers were 150 ft. apart (see also CASTLE and FORTIFICATION).

From the architectural point of view, the towers which are of chief interest are those of ecclesiastical and secular buildings, those in Italy being nearly always isolated and known as campanili (see CAMPANILE). In England the earliest known are the Anglo-Saxon towers, the best examples of which are those at Earl's Barton, Monkwearmouth, Barnack, Barton-on-Humber and Sompting; they were nearly always square on plan and situated at the west end, in an axial line with the nave, their chief characteristics being the long-and-short work of the masonry at the quoins, the decoration of the wall with thin pilaster strips, and the slight setting back of the storeys as they rose. There are a few examples of central Anglo-Saxon towers, as at St Mary's, Dover; Breamore, Hants; and Dunham Major, Norfolk; and, combined with western towers, at Ramsay and Ely; twin western towers existed at Exeter. Contemporary with these Saxon towers are many examples in France, but they are invariably central towers, as at Germigny-des-Près and at Querqueville in Normandy; in Germany the twin towers of Aix-la-Chapelle are the best known. As a rule the single western tower is almost confined to England, prior to the end of the 11th century, when there are many examples throughout Germany. In Norman times in England, central towers are more common, and the same obtains in France, where, however, they are sometimes carried to a great height, as at Périgueux, where the wall decoration consists of pilasters in the lower storeys, and semi-detached columns above, probably based on that of the Roman amphitheatre there: otherwise the design of the Romanesque church towers is extremely simple, depending for its effect on the good masonry and the enrichment of the belfry windows. In later periods flat buttresses are introduced, and these gradually assume more importance and present many varieties of design; greater apparent height is given to the tower by the string courses dividing the second storeys, and by rich blank arcading on them, the upper storey with the belfry windows forming always the most important feature of the tower. In those towers which are surmounted by spires (*q.v.*) the design of the latter possesses sometimes a greater interest both in England and France. A very large number of the towers of English cathedrals and churches have flat roofs enclosed with lofty battlemented parapets and numerous pinnacles and finials; in France such terminations are not found, and in Germany the high pitched roof is prevalent every where, so that the numerous examples in England have a special interest; sometimes the angle buttresses are grouped to carry octagonal pinnacles, and sometimes, as at Lincoln and Salisbury, octagonal turrets rise from the base of the tower.

Among the finest examples are those of Canterbury, Ely, York, Gloucester, Lincoln and Worcester cathedrals; among churches, those of the minster at Beverley; St Mary's, St Neots (Huntingdonshire); St Stephen's, Bristol, St Giles, Wrexham (Denbighshire—in many respects the most beautiful in England); St Mary Magdalene, Taunton; Magdalen College, Oxford, St Botolph, Boston, crowned with an octagonal tower; St Mary's, Ilminster (Somersetshire) and Malvern (Worcestershire); and the isolated towers at Chichester, Evesham and Bury St Edmund's.

So far reference has been made only to central and western towers, the latter not always placed, like the Anglo-Saxon towers, in the axial line of the nave, but sometimes on the north or south side of the west end; and as a rule these are only found in England. In France and Germany, however, they are greatly increased in number; thus in Reims seven towers with spires were contemplated, according to Viollet-le-Duc, but never completed; at Chartres eight towers, and at Laon seven, of which six are completed; in Germany the cathedrals of Mayence and Spires and two of the churches in Cologne have from four to seven towers; and at Tournai cathedral, in Belgium, are seven towers. In many of the churches in Norfolk and Suffolk the western tower is circular, owing probably to the fact that, being built with stone of small dimensions, the angles of the quoins would have been difficult to construct. In some of the French towns, isolated towers were built to contain bells, and were looked upon as municipal constructions; of these there are a few left, as at Béthune, Évreux, Amiens and Bordeaux, the latter being a double tower, with the bells placed in a roof between them.

The towers of secular buildings are chiefly of the town halls, of which there are numerous examples throughout France and Belgium, such as those of the hôtel de ville at St Antonin (13th century) and Compiègne, both in France; at Lübeck, Danzig and Münster in Germany; and Brussels, Bruges and Oudenarde in Belgium. (R. P. S.)

TOWER OF LONDON, THE, an ancient fortress on the east side of the City of London, England, on the north bank of the river Thames. On a slight elevation now called the Tower Hill, well protected by the river and its marshes, and by woods to the north, there was a British stronghold. Tradition, however, pointed to Julius Caesar as the founder of the Tower (Shakespeare, *Richard III.*, III., i; and elsewhere), and remains of Roman fortifications have been found beneath the present site. The Tower contains barracks, and is the repository of the regalia. It covers an irregular hexagonal area, and is surrounded by a ditch, formerly fed by the Thames, but now dry. Gardens surround it on the north and west, and an embankment borders the river on the south. Two lines of fortifications enclose the inner bail, in which is the magnificent White Tower or Keep, flanked by four turrets. This was built by Gundulf, bishop of Rochester, *c.* 1078. Its exterior was restored by Sir Christopher Wren, but within the Norman work is little altered. Here may be seen a collection of old armour and instruments of torture, the rooms said to have been Sir Walter Raleigh's prison, and the magnificent Norman chapel of St John. Among the surrounding buildings are the barracks, and the chapel of St Peter ad Vincula, dating from the early part of the 14th century, but much altered in Tudor times. The Ballium Wall, the inner of the two lines of fortification, is coeval with the keep. Twelve towers rise from it at intervals, in one of which, the Wakefield Tower, the Regalia or crown jewels are kept. The chief entry to the fortress is through the Middle Tower on the west, across the bridge over the moat, and through the Byward Tower. The Lion Gate under the Middle Tower took name from a menagerie kept here from Norman times until 1834. On the south, giving entry from the river through St Thomas Tower and the Bloody Tower, is the famous Traitor's Gate, by which prisoners of high rank were admitted. The chief historical interest of the Tower lies in its association with such prisoners. The Beauchamp Tower was for long the place of confinement, but dungeons and other chambers in various parts of the building are also associated with prisoners of fame. Executions took place both within the Tower and on Tower Hill. Many of those executed were buried in the chapel of St Peter ad Vincula, such as Sir Thomas More, Henry VIII.'s queens, Anne Boleyn and Katharine Howard, Lady Jane Grey and her husband Dudley, Sir Walter Raleigh, and the duke of Monmouth. The Tower was not only a prison from Norman times until the 19th century, but was a royal residence at intervals from the reign of Stephen, if not before. The royal palace was demolished by order of Cromwell. The tower is under the governorship of a constable. The attendant staff, called Yeomen of the Guard or familiarly "Beefeaters," still wear their picturesque Tudor costume.

AUTHORITIES.—W. Hepworth Dixon, *Her Majesty's Tower* (London, 1869); Lord Ronald Sutherland Gower, *The Tower of London* (London, 1901).

TOWN, in its most general sense, a collection or aggregation of inhabited houses larger than a village. The O. Eng. *tun* (M. Eng. *toun*) meant originally a fence or enclosure, cf. Ger. *zaun*, hedge, hence an enclosed place. The Scottish and Northern English use of the word for a farmhouse and its buildings, a farmstead, preserves this original meaning, and is paralleled by the Icel. *tun*, homestead, dwelling-house. A cognate Celtic form meaning a fastness, a strong place, appears in Gael. and Irish *dun*, Welsh, *din*, fortress, hill-fort (cf. Welsh *dinas*, town). This is familiar from the many Latinized names of places, *e.g. Lugdunum*, *Augustodunum*, &c. In English law "town" is not a word defined by statute. For purposes of local government there are boroughs, urban districts and rural districts, but many urban districts are rural in character and the distinction is purely an administrative one (see BOROUGH; CITY; COMMUNE (MEDIEVAL); MUNICIPIUM; ENGLAND: *Local Government*, and the sections on local administration under various country headings). The meaning attached to the term "township" in the local administration of the United States is treated under UNITED STATES: *Local Government*.

TOWNELEY (or TOWNLEY), **CHARLES** (1737–1805), English archaeologist and collector of marbles, was born at Towneley, the family seat, near Burnley in Lancashire, on the 1st of October 1737. He was educated at the college of Douai, and subsequently under John Turberville Needham, the physiologist and divine. In 1758 he took up his residence at Towneley, where he lived the ordinary life of a country gentleman until about 1765, when he left England to study ancient art, chiefly at Rome. He also made several excursions to the south of Italy and Sicily. In conjunction with Gavin Hamilton, the artist, and Thomas Jenkins, a banker in Rome, he got together a splendid collection of antiquities, which was deposited in two houses bought by him for the purpose in Park Street, Westminster, where he died on the 3rd of January 1805. His solitary publication was an account of an ancient helmet found at Ribchester. His marbles, bronzes, coins, and gems were purchased by the British Museum for about £28,000, and form part of the Graeco-Roman collection.

For an account of the antiquities see Sir Henry Ellis's *The Townley Gallery* (1836), and A. T. F. Michaelis's *Ancient Marbles in Great Britain* (1882).

TOWNLEY, JAMES (1714–1778), English dramatist, second son of Charles Townley, merchant, was born in London on the 6th of May 1714. Educated at Merchant Taylors' School and at St John's College, Oxford, he took holy orders, being ordained priest on the 28th of May 1738. He was lecturer at St Dunstan's in the East, chaplain to the lord mayor, then under-master at Merchant Taylors' School until 1753, when he became grammar master at Christ's Hospital. In 1760 he became head master of Merchant Taylors' School, where in 1762 and 1763 he revived the custom of dramatic performances. He retained his head-mastership until his death on the 5th of July 1778. He took a keen interest in the theatre, and it has been asserted that many of David Garrick's best productions and revivals owed much to his assistance. He was the author, although the fact was long concealed, of *High Life below Stairs*, a two-act farce presented at Drury Lane on the 31st of October 1759; also of *False Concord* (Covent Garden, March 20, 1764) and *The Tutor* (Drury Lane, Feb. 4, 1765).

TOWNSHEND, CHARLES (1725–1767), English politician, was the second son of Charles, 3rd Viscount Townshend, who married Audrey (d. 1788), daughter and heiress of Edward Harrison of Ball's Park, near Hertford, a lady who rivalled her son in brilliancy of wit and frankness of expression. Charles was born on the 29th of August 1725, and was sent for his education to Leiden and Oxford. At the Dutch university, where he matriculated on the 27th of October 1745, he associated with a small knot of English youths, afterwards well known in various circles of life, among whom were Dowdeswell, his subsequent rival in politics, Wilkes, the witty and unprincipled reformer, and Alexander Carlyle, the genial Scotchman, who devotes some of the pages of his *Autobiography* to chronicling their sayings and their doings. He represented Great Yarmouth in parliament from 1747 to 1761, when he found a seat for the treasury borough of Harwich. Public attention was first drawn to his abilities in 1753, when he delivered a lively attack, as a younger son who might hope to promote his advancement by allying himself in marriage to a wealthy heiress, against Lord Hardwicke's marriage bill. Although this measure passed into law, he attained this object in August 1755 by marrying Caroline (d. 1794), the eldest daughter of the 2nd duke of Argyll and the widow of Francis, Lord Dalkeith, the eldest son of the 2nd duke of Buccleuch. In April 1754 Townshend was transformed from the position of a member of the board of trade, which he had held from 1749, to that of a lord of the admiralty, but at the close of 1755 his passionate attack against the policy of the ministry, an attack which shared in popular estimation with the scathing denunciations of Pitt, the supreme success of Single-Speech Hamilton, and the hopeless failure of Lord Chesterfield's illegitimate son, caused his resignation. In the administration which was formed in November 1756, and which was ruled by Pitt, the lucrative office of treasurer of the chamber was given to Townshend, and in the following spring he was summoned to the privy council.

With the accession of the new monarch in 1760 this volatile politician transferred his attentions from Pitt to the young king's favourite, Bute, and when in 1761, at the latter's instance, several changes were made in the ministry, Townshend was promoted to the post of secretary-at-war. In this place he remained after the great commoner had withdrawn from the cabinet, but in December 1762 he threw it up. Bute, alarmed at the growth in numbers and in influence of his enemies, tried to buy back Townshend's co-operation by sundry tempting promises, and at last secured his object in March 1763 with the presidency of the board of trade. When Bute retired and George Grenville accepted the cares of official life, the higher post of first lord of the admiralty fell to Townshend's lot, but with his usual impetuosity he presumed to designate one of his satellites, Sir William Burrell (1732–1796), to a place under him at the board, and the refusal to accept the nomination led to his exclusion from the new administration. While in opposition his mind was swayed to and fro with conflicting emotions of dislike to the head of the ministry and of desire to share in the spoils of office. The latter feeling ultimately triumphed; he condescended to accept in the dying days of Grenville's cabinet, and to retain through the "lutestring" administration of Lord Rockingham—"pretty summer wear," as Townshend styled it, "but it will never stand the winter"—the highly paid position of paymaster-general, refusing to identify himself more closely with its fortunes as chancellor of the exchequer. The position which he refused from the hands of Lord Rockingham he accepted from Pitt in August 1766, and a few weeks later his urgent appeals to the great minister for increased power were favourably answered, and he was admitted to the inner circle of the cabinet. The new chancellor proposed the continuance of the land tax at four shillings in the pound, while he held out hopes that it might be reduced next year to three shillings, whereupon his predecessor, William Dowdeswell, by the aid of the landed gentlemen, carried a motion that the reduction should take effect at once. This defeat proved a great mortification to Lord Chatham, and in his irritation against Townshend for this blow, as well as for some acts of insubordination, he meditated the removal of his showy colleague. Before this could be accomplished Chatham's mind became impaired, and Townshend, who was the most determined and influential of his colleagues, swayed the ministry as he liked, pledging himself to find a revenue in America with which to meet the deficiency caused by the reduction in the land tax. His wife was created (August 1767) baroness of Greenwich, and his elder brother George, the 4th viscount, was made lord-lieutenant of Ireland. He himself delivered in the House of Commons many speeches unrivalled in parliamentary history for wit and recklessness; and one of them still lives in history as the "champagne speech." His last official act was to carry out his intention by passing through parliament resolutions, which even his colleagues deprecated in the cabinet, for taxing several articles, such as glass, paper and tea, on their importation into America, which he estimated would produce the insignificant sum of £40,000 for the English treasury, and which shrewder observers prophesied would lead to the loss of the American colonies. Soon after this event he died somewhat suddenly on the 4th of September 1767.

The universal tribute of Townshend's colleagues allows him the possession of boundless wit and ready eloquence, set off by perfect melody of intonation, but marred by an unexampled lack of judgment and discretion. He shifted his ground in politics with every new moon, and the world fastened on him the nickname, which he himself adopted in his "champagne" speech, of the weathercock. His official knowledge was considerable; and it would be unjust to his memory to ignore the praises of his contemporaries or his knowledge of his country's commercial interests. The House of Commons recognized in him its spoilt child, and Burke happily said that "he never thought, did or said anything" without judging its effect on his fellow members.

A *Memoir* by Percy Fitzgerald was published in 1866. See also W. E. H. Lecky, *History of England* (1892); and Horace Walpole, *Memoirs of the Reign of George III.*, edited by G. F. R. Barker (1894).

TOWNSHEND, CHARLES TOWNSHEND, 2ND VISCOUNT (1674–1738), English statesman, was the eldest son of Sir Horatio Townshend, Bart. (*c.* 1630–1687), a zealous supporter of Charles II., who was created Baron Townshend in 1661 and Viscount Townshend of Raynham in 1682. The old Norfolk family of Townshend, to which he belonged, is descended from Sir Roger Townshend (d. 1493) of Raynham, who acted as legal adviser to the Paston family, and was made a justice of the common pleas in 1484. His descendant, another Sir Roger Townshend (*c.* 1543–1590), had a son Sir John Townshend (1564–1603), a soldier, whose son, Sir Roger Townshend (1588–1637), was created a baronet in 1617. He was the father of Sir Horatio Townshend.

Charles Townshend succeeded to the peerage in December 1687, and was educated at Eton and King's College, Cambridge. He had Tory sympathies when he took his seat in the House of Lords, but his views changed, and he began to take an active part in politics as a Whig. For a few years after the accession of Queen Anne he remained without office, but in November 1708 he was appointed captain of the yeomen of the guard, having in the previous year been summoned to the privy council. He was ambassador extraordinary and plenipotentiary to the states-general from 1709 to 1711, taking part during these years in the negotiations which preceded the conclusion of the treaty of Utrecht. After his recall to England he was busily occupied in attacking the proceedings of the new Tory ministry. Townshend quickly won the favour of George I., and in September 1714, the new king selected him as secretary of state for the northern department. The policy of Townshend and his colleagues, after they had crushed the Jacobite rising of 1715, both at home and abroad, was one of peace. The secretary disliked the interference of England in the war between Sweden and Denmark, and he promoted the conclusion of defensive alliances between England and the emperor and England and France. In spite of these successes the influence of the Whigs was gradually undermined by the intrigues of Charles Spencer, earl of Sunderland, and by the discontent of the Hanoverian favourites. In October 1716, Townshend's colleague, James Stanhope, afterwards 1st Earl Stanhope, accompanied the king on his visit to Hanover, and while there he was seduced from his allegiance to his fellow ministers by Sunderland, George being led to believe that Townshend and his brother-in-law, Sir Robert Walpole, were caballing with the prince of Wales, their intention being that the prince should supplant his father on the throne. Consequently in December 1716 the secretary was dismissed and was made lord-lieutenant of Ireland, but he only retained this post until the following April.

Early in 1720 a partial reconciliation took place between the parties of Stanhope and Townshend, and in June of this year the latter became president of the council, a post which he held until February 1721, when, after the death of Stanhope and the forced retirement of Sunderland, a result of the South Sea bubble, he was again appointed secretary of state for the northern department, with Walpole as first lord of the treasury and chancellor of the exchequer. The two remained in power during the remainder of the reign of George I., the chief domestic events of the time being the impeachment of Bishop Atterbury, the pardon and partial restoration of Lord Bolingbroke, and the troubles in Ireland caused by the patent permitting Wood to coin halfpence. Townshend secured the dismissal of his rival, John Carteret, afterwards Earl Granville, but soon differences arose between himself and Walpole, and he had some difficulty in steering a course through the troubled sea of European politics. Although disliking him, George II. retained him in office, but the predominance in the ministry passed gradually but surely from him to Walpole. Townshend could not brook this. So long, to use Walpole's witty remark, as the firm was Townshend and Walpole all went well with it, but when the positions were reversed jealousies arose between the partners. Serious differences of opinion concerning the policy to be adopted towards Prussia and in foreign politics generally led to a final rupture in 1730. Failing, owing to Walpole's interference, in his efforts to procure the dismissal of a colleague and his replacement by a personal friend, Townshend retired on the 15th of May 1730. His remaining years were passed at Raynham, where he interested himself in agriculture and was responsible for introducing into England the cultivation of turnips on a large scale and for other improvements of the kind. He died at Raynham on the 21st of June 1738.

Townshend was twice married—first to Elizabeth (d. 1711), daughter of Thomas Pelham, 1st Baron Pelham of Laughton, and secondly to Dorothy (d. 1726), sister of Sir Robert Walpole. He had eight sons. The eldest son, Charles, the 3rd viscount (1700–1764), was called to the House of Lords in 1723. The second son, Thomas Townshend (1701–1780), was member of parliament for the university of Cambridge from 1727 to 1774; his only son, Thomas Townshend (1733–1800), who was created Baron Sydney in 1783 and Viscount Sydney in 1789, was a secretary of state and leader of the House of Commons from July 1782 to April 1783, and from December 1783 to June 1789 again a secretary of state, Sydney in New South Wales being named after him; his grandson, John Robert Townshend (1805–1890), the 3rd viscount, was created Earl Sydney in 1874, the titles becoming extinct at his death. Charles Townshend's eldest son by his second wife was George Townshend (1715–1769), who after serving for many years in the navy, became an admiral in 1765. The third viscount had two sons, George, 1st Marquess Townshend, and Charles Townshend, who are separately noticed.

For the 2nd viscount see W. Coxe, *Memoirs of Sir Robert Walpole* (1816); W. E. H. Lecky, *History of England in the 18th Century* (1892); and Earl Stanhope, *History of England.*

TOWNSHEND, GEORGE TOWNSHEND, 1ST MARQUESS (1724–1807), eldest son of Charles, 3rd Viscount Townshend (1700–1764), and brother of the politician Charles Townshend (*q.v.*), was born on the 28th of February 1724, his godfather being George I. Joining Cope's dragoons as a captain, he saw some service in the Netherlands in 1745, and as a member of the duke of Cumberland's staff was present at Culloden. Afterwards he accompanied the duke to the Netherlands, and was present at Lauffeld. By 1750 he had become lieutenant-colonel in the 1st Foot Guards, but differences with the duke of Cumberland led to his retirement in that year. This difference soon became hostility, and, coupled with his dread of permanent armies, caused him to give vehement support to the Militia Bill. In this matter his views and his methods of expressing them raised up a host of enemies. The retirement of the duke after the disastrous campaign in North Germany in 1757 brought Townshend back to active service as a colonel, and in 1758 he sailed for North America as one of Wolfe's three brigadiers. In the long and painful operations against Quebec he showed himself a capable officer, but his almost open dissatisfaction with Wolfe's methods sensibly added to the difficulty of the enterprise. At the battle of the Heights of Abraham the command, on the death of Wolfe and the wounding of Monckton, devolved upon Townshend, whose over-caution for a time imperilled the success of the British arms. The loss of Montcalm, however, had similarly paralyzed the French, and the crisis passed. Townshend sent home a despatch, announcing the fall of Quebec, which at once became the butt of the wits and the object of criticism of a more serious kind; and when, Monckton having taken over the command in Canada, Townshend returned to England to enjoy, as he hoped, the hero-worship of the public, he was soon involved in bitter controversies. He succeeded to the title in 1764 on his father's death, and in 1767, through his brother's influence, was made lord-lieutenant of Ireland. The story of his viceroyalty may be read in the article on him in the *Dict. Nat. Biog.*, and in Lecky's *History of England in the 18th Century* (vol. iv.). With the best will in the world, and in spite of excellent capacity, he came into continual conflict with the Irish House of Commons in his attempt to form an English party in Ireland, and he excited unmeasured abuse. In 1772 he was recalled. In 1787 he was created Marquess Townshend of Rainham. He died on the 14th of September 1807.

Townshend was twice married—first to Charlotte, Baroness de Ferrars (d. 1770) and secondly to Anne Montgomery (d. 1819). His eldest son George (1755–1811), who became the second marquess, had succeeded to the barony of de Ferrars in 1770 and had been created earl of Leicester in 1784. Although he was in turn master of the mint, joint postmaster-general and lord steward of the royal household, he did not take much part in politics, but showed a great taste for antiquarian studies. His elder son, George Ferrars Townshend, the 3rd marquess (1778–1855), was disinherited by his father for conduct which also compelled him to reside outside England. When he died at Genoa in December 1855 the earldom of Leicester became extinct. The marquessate, however, passed to a cousin, John Townshend (1798–1863), who became the 4th marquess. John James Dudley Stuart Townshend (b. 1866), who became the 6th marquess in 1899, came prominently before the public in 1906 in consequence of a judicial inquiry into his sanity, the decision being that he was not capable of managing his own affairs.

TOWNSVILLE, a town of Elphinstone county, Queensland, Australia, 870 m. direct N.W. of Brisbane. Pop. (1901), 12,717. It is the seat of the Anglican bishop of North Queensland and has a cathedral and several handsome buildings, including the supreme court and the custom-house. It is picturesquely situated partly on the slopes of Castle Hill and Melton Hill, and partly on the banks of Ross Creek, which is spanned by the Victoria Bridge, a swing bridge 550 ft. in length, worked by hydraulic power. The tidal harbour is enclosed by stone breakwaters, and large vessels enter and load frozen meat direct from the refrigerator cars. The port is an outlet for a wide area of pastoral country and for several goldfields, and has regular communication with all ports north and south by lines of steamers. The immigration barracks on Ross Island have accommodation for five hundred persons. The railway station is the terminus of the Northern line, which extends 236 m. to Hughenden. Townsville was founded in 1864 by John Medwin Black and named after his partner Captain Towns. A municipal charter was granted in 1866.

TOWTON, a village of Yorkshire, England, 2½ m. S. of Tadcaster, the scene of a battle fought on Palm Sunday, the 29th of March 1461, between the armies of York and Lancaster. The party of Lancaster had lately won the battle of St Albans, but, unable to gain admission into London, and threatened by the approach of Edward the young duke of York from the west of England, was compelled to fall back northward. York, having been proclaimed as Edward IV. on the 2nd, 3rd and 4th of March 1460/1461, followed them up into Yorkshire, and on the 27th his leading troops surprised the passage of the Aire at Ferrybridge. The Lancastrians were encamped at Towton, some miles away, covering Tadcaster and York; but a force under Lord Clifford was promptly sent out, recaptured Ferrybridge by surprise, and cut to pieces the Yorkist garrison. About the same time, however, Edward's van, under Lord Fauconberg, an experienced soldier, crossed the Aire higher up, and Clifford was compelled to retire. He was closely pressed, and at Dintingdale, within a few furlongs of his own camps, was cut off and killed with nearly all his men. Edward's main body was now close at hand, and the Lancastrians drew up on their chosen battlefield early on the 29th. This field was an elevated plateau, with steep slopes, between the present Great North Road and the river Cock, cut in two by a depression called Towton Dale. On opposite sides of this depression stood the two armies, that of York facing north, their opponents southward. Both lines of battle were very dense. On a front of little more than a thousand yards the Lancastrian party had nearly 60,000 men. Edward's force (less than 50,000) was not all present, the rear "battle" under Norfolk being still distant. Snow and sleet blew in the faces of the Lancastrians and covered the field of battle. The skilful Fauconberg used this advantage to the utmost. Aided by the wind, his archers discharged flights of arrows against the enemy, who replied blindly and feebly, hampered by snow and wind. The Yorkists withdrew until the enemy had exhausted their quivers, and then advanced afresh. Their arrows soon stung the Lancastrians into a wild and disorderly charge. Suffering severe losses the latter closed with Edward's line of battle. No quarter was given by either party, and on the narrow front the numerical superiority of the Lancastrians counted for little. The long, doubtful and sanguinary struggle was only decided by the arrival of Norfolk's corps, which charged the enemy in flank. Driven backwards and inwards, the Lancastrians were in a desperate position, for their only way of escape to Tadcaster crossed the swollen waters of the Cock by a single narrow and difficult ford, and when, after a stubborn struggle, they finally broke and fled, they were slaughtered in thousands as they tried to cross. At the close of the day the defeated army had ceased to exist. Twenty-five thousand Lancastrian and eight thousand Yorkist dead were buried in and about Towton. The neighbourhood of the battlefield contains many relics and memorials of this, the greatest battle hitherto fought on English soil. Particularly well preserved is the tomb of Lord Dacre, a prominent Lancastrian, in Saxton churchyard.

See R. Brooke, *Visits to English Battlefields* (London, 1857); C. R. B. Barrett, *Battles and Battlefields of England* (London, 1896); H. B. George, *Battles of English History* (London, 1895).

TOXICOLOGY, the name of that branch of science which deals with poisons, their effects and antidotes, &c. For the general treatment of the subject and for the law relating to the sale thereof see POISONS, and for the criminal law see MEDICAL JURISPRUDENCE. The term "toxic," meaning poisonous, is derived from Gr. *τόξον*, bow, owing to the custom of smearing arrows with poison.

TOXODONTIA, a sub-order of extinct South American Tertiary ungulate mammals typified by the genus *Toxodon*, so named from the bow-like curvature of the molar teeth. They all show signs of distant kinship to the Perissodactyla, as regards both limb-structure and dentition; while some exhibit resemblance to the Rodents and Hyraxes—resemblances which, however, are probably to be attributed to parallelism in development.

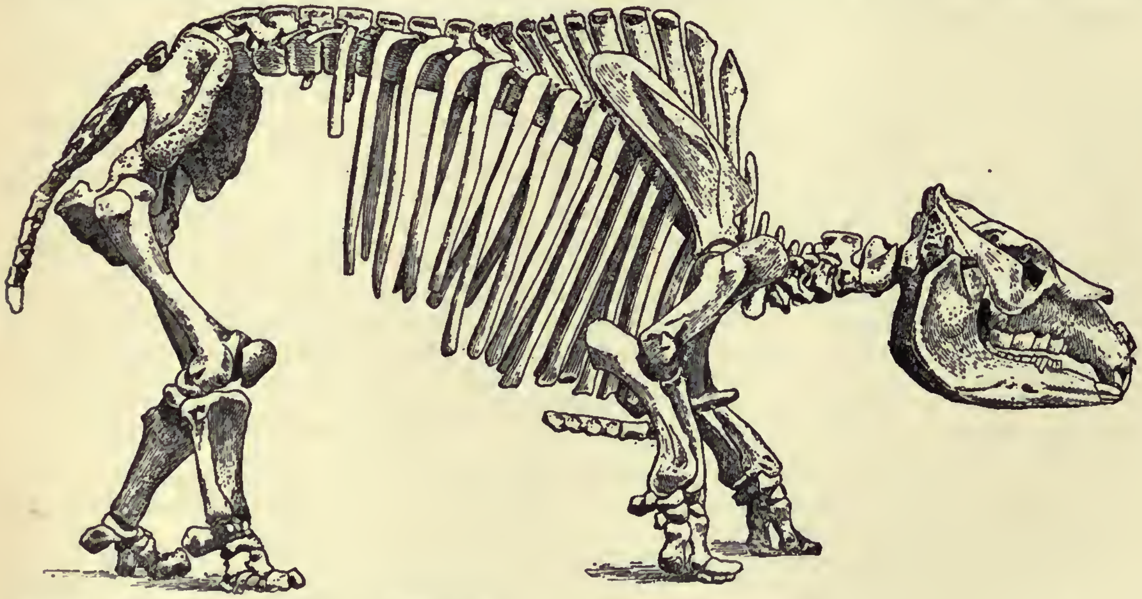
Under the sub-order Toxodontia may be included not only the typical *Toxodon*, but the more aberrant *Typotherium* (fig. 1) of the Pleistocene of Buenos Aires and the smaller *Pachyrucus* and *Hegetotherium* of the Patagonian Santa Cruz beds. All the members of the sub-order have tall-crowned and curved cheek-teeth, some or all of which generally have persistent pulps, while at least one pair of incisors in each jaw is rootless. The bodies of the cervical vertebrae have flat articular surfaces, the bones of the two rows of the carpus alternate, and in the tarsus the navicular articulates with the calcaneum, which, as in the Artiodactyla, is articulated to the fibula, while the astragalus, which is slightly grooved above, is formed on the Perissodactyle plan. The number of toes varies between three and five, of which the middle one is the largest, and the femur may or may not have a third trochanter. The Typotheriidae and Pachyrucidae are remarkable among the Ungulates for

(After Gervais.)

FIG. 1.—Skull of *Typotherium cristatum*, from the Pampas Formation of Buenos Aires. ($\frac{1}{4}$ nat. size.)

the retention of clavicles, and for their curious approximation in dentition and certain characters of the skeleton to the Rodentia. The dental formula of *Typotherium* is *i.* $\frac{1}{2}$, *c.* $\frac{0}{0}$, *p.* $\frac{2}{1}$, *m.* $\frac{3}{3}$; that of the smaller Patagonian forms differs by the larger number ($\frac{3}{3}$) of premolars. The toes were unguiculate rather than ungulate in character, except the hind ones (four in number) of *Typotherium*. Certain allied Patagonian forms, such as *Argyrohyrax*, have been supposed to be related to the Hyraxes.

The Toxodontidae differ from the preceding families by the loss of the clavicles and the reduction of the digits to three in each foot. The typical genus *Toxodon* is represented by animals the size of a



(From British Museum [Nat. His.] Guide to the Fossil Mammalia.)

FIG. 2.—Skeleton of the Toxodon (*Toxodon platensis*). From the Pampean Formation of Argentina. (About $\frac{1}{10}$ nat. size.)

rhinoceros, of which the entire skeleton is now known (fig. 2). The teeth, of which the formula is *i.* $\frac{2}{3}$, *c.* $\frac{0}{1}$ *p.* $\frac{3-4}{2-4}$, *m.* $\frac{3}{3}$, all grow from persistent pulps; those of the cheek-series are very tall, highly curved, and with a simplified crown-structure. In the older *Nesodon*, on the other hand, the cheek-teeth are shorter-crowned, and depart less widely from a generalized Perissodactyle type, the total number of teeth being forty-four, and there being scarcely any gap in the series. Very remarkable changes occur in the dentition as age advances, most of the teeth eventually developing roots, although the second pair of incisors in each jaw was rootless. The complete skeleton is not yet known, but it is ascertained that the femur differs from that of *Toxodon* in the retention of a third trochanter.

Toxodon is typified by *T. platensis* from the Pampean formation of Buenos Aires. *Toxodontotherium* and *Xotodon* are allied but rather older types. *Nesodon* is from the Santa Cruz beds of Patagonia, the typical *N. imbricatus* having a skull about a foot in length, but *N. ovinus* was a smaller animal, about the size of a sheep.

(R. L.*)

TOY, CRAWFORD HOWELL (1836–   ), American Hebrew scholar, was born in Norfolk, Virginia, on the 23rd of March 1836. He graduated at the university of Virginia in 1856, and studied at the university of Berlin in 1866–1868. In 1869–1879 he was professor of Hebrew in the Southern Baptist Theological Seminary (first in Greenville, South Carolina, and after 1877 in Louisville, Kentucky), and in 1880 he became professor of Hebrew and Oriental languages in Harvard University, where until 1903 he was also Dexter lecturer on biblical literature.

He wrote *The Religion of Israel* (1882); *Quotations from the Old Testament in the New Testament* (1884); *Judaism and Christianity* (1890); and the *Book of Proverbs* (1899) in the "International Critical Commentary"; and edited a translation of Erdmann's commentary on Samuel (1877) in Lange's commentaries; Murray's *Origin of the Psalms* (1880); and, in Haupt's *Sacred Books of the Old Testament*, the Book of Ezekiel (Hebrew text and English version, 1899).

TOY (an adaptation of Du. *tuig*, tools, implements, stuff, *speltuig*, playthings, *i.e.* stuff to play with, *spelen*, to play), a child's plaything, also a trifle, a worthless, petty ornament, a gew-gaw, a bauble. Children's toys and playthings survive from the most remote periods of man's life on the earth, though many so-called diminutive objects made and used by primitive man, sometimes classified as playthings, may have been workmen's models, votive offerings or sepulchral objects. A large number of wooden, earthenware, stone or metal dolls remain with which the children of ancient Egypt once played; thus in the British Museum collection there is a flat painted wooden doll with strings of mud-beads representing the hair, a bronze woman doll bearing a pot on her head, an earthenware doll carrying and nursing a child; some have movable jointed arms. There are also many toy animals, such as a painted wooden calf, a porcelain elephant with a rider; this once had movable legs, which have disappeared. Balls are found made of leather stuffed with hair, chopped straw and other material, and also of blue porcelain or papyrus. Jointed dolls, moved by strings, were evidently favourite playthings of the Greek and Roman children, and small models of furniture, chairs, tables, sets of jugs painted with scenes of children's life survive from both Greek and Roman times. Balls, tops, rattles and the implements of numerous games, still favourites in all countries and every age, remain to show how little the amusements of children have changed.

See also DOLL; TOP; PLAY; and for the history of toys, with their varying yet unchanging fashions, see H. R. d'Allemagne, *Histoire des Jouets*, and F. N. Jackson, *Toys of other Days* (1908).

TOYNBEE, ARNOLD (1852–1883), English social reformer and economist, second son of Joseph Toynbee (1815–1866), a distinguished surgeon, was born in London on the 23rd of August 1852. He had originally intended to enter the army, but ill health and a growing love of books changed his plans, and he settled down to read for the bar. Here again the same causes produced a change of purpose, and he entered as a student at Pembroke College, Oxford. Finding himself by no means at ease in that college he migrated after two years to Balliol College. Continued ill health prevented his reading for honours, but he made so deep an impression on the authorities of his college that on taking his degree he was appointed lecturer and tutor to students preparing for the Indian civil service. He devoted himself to the study of economics and economic history. He was active also as a practical social reformer, taking part in much public work and delivering lectures in the large industrial centres on economic problems. He overtaxed his strength, and after lecturing in London in January 1883 he had a complete break-down, and died of inflammation of the brain at Wimbledon on the 9th of March.

Toynbee had a striking influence on his contemporaries, not merely through his intellectual powers, but by his strength of character. He left behind him a beautiful memory, filled as he was with the love of truth and an ardent and active zeal for the public good. He was the author of some fragmentary pieces, published after his death by his widow, under the title of *The Industrial Revolution*. This volume deserves attention both for its intrinsic merit and as indicating the first drift of a changing method in the treatment of economic problems. He, however, fluctuated considerably in his opinion of the Ricardian political economy, in one place declaring it to be a detected "intellectual imposture," whilst elsewhere, apparently under the influence of Bagehot, he speaks of it as having been in recent times "only corrected, re-stated, and put into the proper relation to the science of life," meaning apparently, by this last, general sociology. He saw that the great help in the future for the science of economics must come from the historical method, to which in his own researches he gave preponderant weight. Toynbee's interest in the poor and his anxiety to be personally acquainted with them led to his close association with the district of Whitechapel in London, where the Rev. Canon S. A. Barnett (*q.v.*) was at that time vicar—an association which was commemorated after his death by the social settlement of Toynbee Hall, the first of many similar institutions erected in the East End of London for the purpose of uplifting and brightening the lives of the poorer classes.

See F. C. Montague's *Arnold Toynbee* (Johns Hopkins University Studies, 1889); Lord Milner's *Arnold Toynbee: a Reminiscence* (1901); and L. L. Price's *Short History of Political Economy in England* for a criticism of Toynbee as an economist.

TRABEATED, the architectural term given to those styles in which the architrave or beam (Lat. *trabs*) is employed instead of the arch, in the latter case the term "arcuated" being used. The principal trabeated styles are the Egyptian, Persian, Greek, Lycian, nearly all the Indian styles, the Chinese, Japanese and South American styles, in all cases owing their origin to the timber construction, for which reason the term post-and-lintel architecture is sometimes applied to it.

TRACERY, a late coined word from "trace," track, Lat. *trahere*, to draw; the term given in architecture (French equivalents are *réseau*, *remplissage*) to the intersecting rib-work in the upper part of a Gothic window; applied also to the interlaced work of a vault, or on walls, in panels and in tabernacle work or screens. The tracery in windows is usually divided into two sections, plate tracery and rib or bar tracery, the latter rising out of the former, and entirely superseding it in the geometrical, flowing and rectilineal designs. The windows of the Early English period were comparatively narrow slits, and were sometimes grouped together under a single enclosing arch; the piercing of the tympanum of this arch with a circular light produced what is known as plate tracery, which is found in windows of the late 12th century, as in St Maurice, York, but became more common in the first half of the 13th century. In England the opening pierced in the head was comparatively small, its diameter never exceeding the width of one of the windows below, but in France it occupied the full width of the enclosing arch and was filled with cusping, and sometimes, as in Chartres, with cusping in the centre and a series of small quatrefoils round, all pierced on one plane face. In order further to enrich the mullions and arches of the window, they were moulded, as in Stowe church, Kent; the other portions were pierced; and finally, to give more importance to the principal lights, additional depth was given to their mouldings, so that they gradually developed into bar or rib tracery, of which the earliest examples in England are those in Westminster Abbey (*c.* 1250) and Netley Abbey near Southampton. Henceforth that which is described in architecture as the "element" ruled the design of the window, and led to the development of geometrical tracery, in which the bars or ribs are all about equidistant from one another. In windows of three lights the heads of the windows consisted of three circular openings, but with four lights they were grouped in two pairs, with a single circle over each and a larger one at the top in the centre. This led to increased dimensions being given to the moulding of the enclosing arches and the upper circle, forming virtually two planes in the tracery. In the great east window at Lincoln, with eight lights, there was a double subdivision and three planes, and here the upper circle was filled with semicircles, so that the openings were all about the same width. In France the upper circle always maintained its predominance, its subdivisions only retaining the scale. The next development, which would seem to have taken place in Gloucester Cathedral, was the omission of portions of the enclosing circle, so as to allow the ribs to run one into the other, forming therefore lines of double curvature, and giving rise to what is known as flowing or flamboyant tracery, of which the great window in Carlisle Cathedral is the most important example. In this window there are nine lights, the four outer ones in each rib being grouped together; these were not subdivided again, and consequently there are only two planes of tracery. The Perpendicular style which followed might perhaps be considered as a reaction against the abuse of the flowing lines in masonry, were it not that in the earlier examples it appears timidly. At Edington church in Wiltshire (1361), in a five-light window, the centre light is wider than the others and its mullions run straight up into the arch mould. In New College chapel, Oxford (1386), the head of the window is subdivided into narrow vertical lights, each half the width of those below, and this is followed in some counties, but not in all, in the east of England the flamboyant tracery being retained a century later. In St Mary's church, Oxford, with seven lights, all the mullions run straight up into the arch mould, and another feature is introduced, already found in New College chapel, and at a much earlier date in domestic work and in spire-lights, viz. the transom. In the later Perpendicular work another change takes place; the pointed arch struck from two centres is replaced by one struck from four centres, and this eventually in domestic work is superseded by the flat arch.

So far reference has been made only to that which may be called the "element" of the window. The enrichment of the lights with cusping gave additional beauty to them, took away the hard wire-drawn effect of the mouldings, and formed openings of great variety; in some of the windows of the Decorated period the ball flower and other foliage is introduced into the mouldings. In French work the geometrical style lasted till the 14th century, and then there was a lapse in building, so that the flamboyant style which followed, and from which at one time it was assumed that the English mason had derived the style, was apparently taken up by the French after its abandonment in England in favour of Perpendicular work. Germany and Spain have always followed in the wake of the French; and in Italy, where architects preferred to decorate their walls with frescoes, the light from stained glass interfered with their effect, so that there was no demand for huge windows or their subdivision with mullions. At the same time there are many beautiful examples of tracery in Italy, generally in marble, such as those of Giotto's Campanile and the cathedral at Florence, in the Ducal and other palaces at Venice, and in the triforium arcades of Pisa and Siena cathedrals; but they destroyed its effect by the insertion of small capitals to the mullions, which gave horizontal lines where they were not wanted, virtually dividing the window into two parts instead of emphasizing, as was done in the Perpendicular period, the verticality of the mullions.

Among the most glorious features in the Gothic architecture of France, England and Spain are the immense rose windows which were introduced, generally speaking, in the transepts of the cathedrals; the tracery of these follows on the lines of those of the windows, changing from geometrical to Decorated and afterwards to flamboyant. In some respects perhaps the finest examples of plate-tracery were produced in the rose windows of the 13th century.

Thus in France in the rose window of Chartres in the west front (1225), and in England in those of Barfreston in Kent (1180) and Beverley Minster in Yorkshire (1220), plate-tracery of such great beauty is found that it is unfortunate it should have been entirely superseded by rib-tracery. The rose window of Lincoln Cathedral in the north transept is a compromise between the two, as all the lights are cut out independently and in one plane, but there are mouldings round each connected with flowers; in its design and effect this window is far superior to the flamboyant circular window in the south transept. Sometimes a rose window is arranged in the upper portion of an ordinary window, as in the west front of Lichfield Cathedral, and this is constantly found in those of the transepts of the French cathedrals. In the south of Italy, at Bari, Bitonto and Troja, and at Orvieto and Assisi, farther north, there are examples of rose windows, but inferior in design to French and English work, though elaborated with carving. The revival of the 16th century was fatal so far as tracery was concerned; in the place of the flamboyant work of the last phase of Gothic in France semicircular and elliptical curves with poor mouldings were introduced, and the elaborate cusping which gave such interest to the light was omitted altogether, as in St Eustache, Paris. There is, however, one remarkable example in the church of Le Grand Andely, in Normandy, dating from the Henri II. period, in which a return was made to the tracery of the 13th century; but the introduction of Renaissance details in the place of the cusping is not altogether satisfactory, though the general design is fine.

The tracery decorating the vault of Gothic work began on the introduction of the fan vault at Gloucester (see VAULT); it was only a surface decoration, both rib and web being cut out of the same block of stone, and it received further development in the various phases which followed. In the later Perpendicular work the walls and buttresses were all panelled with blank tracery, the most complete example of which is found in Henry VII.'s chapel, Westminster Abbey.

In tabernacle work the tracery is purely of a decorative character, copied in miniature from the mullions, arch-moulds and crockets of Gothic work.

Some of the most beautiful examples of tracery are those on the rood screens of churches, either in stone as in the Jubé of the Madeleine at Troyes, or in wood as in the rood screens of the churches in East Anglia and in Somersetshire; and with this must be included that which was introduced into the panelling of church doors, choir stalls and other church fittings; this was continued, first in the early Renaissance of the 16th century, the finest examples being those of the stalls of King's College, Cambridge, and afterwards in the Jacobean style, in the church at Croxcombe near Shepton Mallet, and the church of St John at Leeds, the two latter ranking as the best work of that late period. (R. P. S.)

TRACHELIUM (Gr. τράχηλος, neck), the term in architecture given to the neck of the capital of the Doric and Ionic orders. In the Greek Doric capital it is the space between the annulets of the echinus and the grooves which marked the junction of the shaft and capital; in some early examples, as in the basilica and temple of Ceres at Paestum and the temple at Metapontum, it forms a sunk concave moulding, which by the French is called the gorge. In the Roman Doric and the Ionic orders the term is given by modern writers to the interval between the lowest moulding of the capital and the top of the astragal and fillet, which were termed the "hypotrachelium" (*q.v.*).

TRACHEOTOMY, the operation of opening the trachea or windpipe (see RESPIRATORY SYSTEM) and inserting a tube (*canula*) to provide a means of breathing when the natural air-passage is obstructed. The operation is by no means easy when performed on a small child, for the wind-pipe is deeply placed amongst important structures. The chief anxiety is in connexion with haemorrhage, for the vessels are large and generally overfull on account of the impairment of the respiration. The higher the opening is made in the trachea the easier and safer is the operation.

TRACHIS, a city of ancient Greece, situated at the head of the Malian Gulf in a small plain between the rivers Asopus and Melas, and enclosed by the mountain wall of Oeta which here extended close to the sea and by means of the Trachinian Cliffs completely commanded the main road from Thessaly. The position was well adapted as an advanced post against invaders from the north, and furthermore guarded the road up the Asopus gorge into the Cephissus valley. Strangely enough, it is not recorded what part Trachis played in the defence of Thermopylae against Xerxes. Its military importance was recognized in 427 B.C. by the Spartans, who sent a garrison to guard the Trachinian plain against the marauding highland tribes of Oeta and built a citadel close by the Asopus gorge with the new name of Heraclea. The Spartans failed to safeguard Heraclea against the Oetaeans and Thessalians, and for a short time were displaced by the Thebans (420). After a bloody defeat at the hands of the neighbouring mountaineers (409) the Spartan governor quarrelled with the native settlers, whom he expelled in 399. Four years later Thebes used her new predominance in central Greece to restore the Trachinians, who retained Heraclea until 371, when Jason of Pherae seized and dismantled it. The fortress was rebuilt, and after 280 served the Aetolians as a bulwark against Celts and Macedonians. It was captured in 191 by the Romans, but restored to the Aetolian League until 146. Henceforth the place lost its importance; in Strabo's time the original site was apparently deserted, and the citadel alone remained inhabited.

Strabo p. 428; Herodotus vii. 198–203; Thucydides iii. 92, v. 51–52; Diodorus xiv. 38, 82; Livy xxxvi. 22–24. W. Leake, *Travels in Northern Greece*, iii. 24–31 (London, 1835); G. B. Grundy, *Great Persian War*, pp. 261–264 (London, 1901). (M. O. B. C.)

TRACHOMA, the name given to a chronic destructive form of inflammation of the conjunctiva of the eye (see EYE: *Diseases*), or "granular conjunctivitis" (Egyptian ophthalmia). It is a contagious disease, associated with dirty conditions, and common in Egypt, Arabia and parts of Europe, especially among the lower class of Jews. Hence it has become important, in connexion with the alien immigration into the United Kingdom and America, and the rejection of those who are afflicted with it. It is important that all cases should be isolated, and that the spread of the infection should be prevented.

TRACHYTE (Gr. τραχύς, rough), in petrology, a group of volcanic rocks which consist mainly of sanidine (or glassy orthoclase) felspar. Very often they have minute irregular steam cavities which make the broken surfaces of specimens of these rocks rough and irregular, and from this character they have derived their name. It was first given by Haüy to certain rocks of this class from Auvergne, and was long used in a much wider sense than that defined above, in fact it included quartz-trachytes (now known as liparites and rhyolites) and oligoclase-trachytes, which are now more properly assigned to andesites. The trachytes are often described as being the volcanic equivalents of the plutonic syenites. Their dominant mineral, sanidine felspar, very commonly occurs in two generations, *i.e.* both as large well-shaped porphyritic crystals and in smaller imperfect rods or laths forming a finely crystalline groundmass. With this there is practically always a smaller amount of plagioclase, usually oligoclase; but the potash felspar (sanidine) often contains a considerable proportion of the soda felspar, and has rather the characteristics of anorthoclase or cryptoperthite than of pure sanidine.

Quartz is typically absent from the trachytes, but tridymite (which likewise consists of silica) is by no means uncommon in them. It is rarely in crystals large enough to be visible without the aid of the microscope, but in thin slides it may appear as small hexagonal plates, which overlap and form dense aggregates, like a mosaic or like the tiles on a roof. They often cover the surfaces of the larger felspars or line the steam cavities of the rock, where they may be mingled with amorphous opal or fibrous chalcedony. In the older trachytes secondary quartz is not rare, and probably sometimes results from the recrystallization of tridymite.

Of the ferromagnesian minerals present augite is the most common. It is usually of pale green colour, and its small crystals are often very perfect in form. Brown hornblende and biotite occur also, and are usually surrounded by black corrosion borders composed of magnetite and pyroxene. Sometimes the replacement is complete and no hornblende or biotite is left, though the outlines of the cluster of magnetite and augite may clearly indicate from which of these minerals it was derived. Olivine is unusual, though found in some trachytes, like those of the Arso in Ischia. Basic varieties of plagioclase, such as labradorite, are known also as phenocrysts in some Italian trachytes. Dark brown varieties of augite and rhombic pyroxene (hypersthene or bronzite) have been observed but are not common. Apatite, zircon and magnetite are practically always present as unimportant accessory minerals.

The trachytes being very rich in potash felspar, necessarily contain considerable amounts of alkalis; in this character they approach the phonolites. Occasionally minerals of the felspathoid group, such as nepheline, sodalite and leucite, occur, and rocks of this kind are known as phonolitic trachytes. The soda-bearing amphiboles and pyroxenes so characteristic of the phonolites may also be found in some trachytes; thus aegirine or aegironic augite forms outgrowths on diopside crystals, and riebeckite may be present in spongy growths among the felspars of the groundmass (as in the trachyte of Berkum on the Rhine). Trachytic rocks are typically porphyritic, and some of the best-known examples, such as the trachyte of Drachenfels on the Rhine, show this character excellently, having large sanidine crystals of tabular form an inch or two in length scattered through their fine-grained groundmass. In many trachytes, however, the phenocrysts are few and small, and the groundmass comparatively coarse. The ferromagnesian minerals rarely occur in large crystals, and are usually not conspicuous in hand specimens of these rocks. Two types of groundmass are generally recognized: the trachytic, composed mainly of long, narrow, sub-parallel rods of sanidine, and the orthophyric, consisting of small, squarish or rectangular prisms of the same mineral. Sometimes granular augite or spongy riebeckite occurs in the groundmass, but as a rule this part of the rock is highly felspathic. Glassy forms of trachyte (obsidians) occur, as in Iceland, and pumiceous varieties are known (in Teneriffe and elsewhere), but these rocks as contrasted with the rhyolites have a remarkably strong tendency to crystallize, and are rarely to any considerable extent vitreous.

Trachytes are well represented among the Tertiary and Recent volcanic rocks of Europe. In Britain they occur in Skye as lava flows and as dikes or intrusions, but they are much more common on the continent of Europe, as in the Rhine district and the Eifel, also in Auvergne, Bohemia and the Euganean Hills. In the neighbourhood of Rome, Naples and the island of Ischia trachytic lavas and tuffs are of common occurrence. In America trachytes are less frequent, being known in S. Dakota (Black Hills). In Iceland, the Azores, Teneriffe and Ascension there are Recent trachytic lavas, and rocks of this kind occur also in New South Wales (Cambewarra range), East Africa, Madagascar, Aden and in many other districts.

Among the older volcanic rocks trachytes also are not scarce, though they have often been described under the names orthophyre and orthoclase-porphyry, while "trachyte" was reserved for Tertiary and Recent rocks of similar composition. In England there are Permian trachytes in the Exeter district, and Carboniferous trachytes are found in many parts of the central valley of Scotland. The latter differ in no essential respect from their modern representatives in Italy and the Rhine valley, but their augite and biotite are often replaced by chlorite and other secondary products. Permian trachytes occur also in Thuringia and the Saar district in Germany.

Closely allied to the trachytes are the *Keratophyres*, which occur mainly in Palaeozoic strata in the Harz (Germany), in the Southern Uplands of Scotland, in Cornwall, &c. They are usually porphyritic and fluidal; and consist mainly of alkali felspar (anorthoclase principally, but also albite and orthoclase), with a small quantity of chlorite and iron oxides. Many of them are lavas, but others are probably dikes or thin intrusions. As the analyses given above will show, they differ from trachytes mainly in being richer in soda. (J. S. F.)

TRACT (from Lat. *tractare*, to treat of a matter, through Provençal *tractat* and Ital. *trattato*), in the literary signification, a work in which some particular subject, or aspect of a subject, is treated. As far as derivation is concerned, a tract is identical with a *treatise*, but by custom the latter word has come to be used for a lengthy monograph on a subject, dealing with it technically and authoritatively, whereas a tract is understood to be brief and rather argumentative than educational. There is, again, the rarer word *tractate*, which is not a tract, in the precise sense, so much as a short treatise.

The word "tract" has come to be used for brief discourses of a moral and religious character only, and in modern practice it seems to be mainly confined to serious and hortatory themes. An essay on poetry, or the description of a passage of scenery, would not be styled a tract. In the Protestant world, the tract which Luther composed in 1520, on the Babylonish captivity, has been taken more or less as the type of this species of literature, which, however, existed long before his day, both in Latin and in the vernacular tongues of western Europe. It is difficult, if not impossible, in early history, to distinguish the tract from other cognate forms of moralizing literature, but it may perhaps be said that the homilies of Ælfric (955–1025?) are the earliest specimens of this class in English literature. Four centuries later Wyclif issued a series of tracts, which were remarkable for their vigour, and exercised a strong influence on medieval theology. Bishop Reginald Pecock published many controversial tracts between 1440 and 1460. Sir Thomas More, John Fisher (d. 1535) and William Tyndale were prominent writers of controversial treatises. It was the Martin Marprelate agitation, in the reign of Elizabeth, which led from 1588 to 1591 to the most copious production of tracts in English literature; of these nearly thirty survive. On the Puritan side the principal writers were John Udall (1560–1592), Henry Barrowe (d. 1593), John Penry (1559–1593) and Job Throckmorton (1545–1601), the tracts being printed in the house of the last-mentioned; on the side of the Established Church the principal authors were Bishop Thomas Cooper (1517–1594) and the poets Lyly and Nash. An enormous collection of tracts was published between 1717 and 1720 in elucidation of what is known as the Bangorian Controversy, set in motion by a sermon of Benjamin Hoadly, bishop of Bangor, on "The Nature of the Kingdom of Christ" (1717). Convocation considered this a treatise likely to impugn and impeach the royal supremacy in religious questions. A vast number of writers took part in the dispute, and Thomas Sherlock (1678–1761) fell into disgrace through the violence of his contributions to it. Convocation was finally obliged to give way.

The most famous collection of tracts published in the course of the 19th century was that produced from 1833 onwards by Newman, Keble and E. B. Pusey, under the title of "Tracts for the Times." Among these Pusey's "Tract on Baptism" (1835) and his "On the Holy Eucharist" (1836) had a profound effect in leading directly to the foundation of the High Church party, so much so that the epithet "Tractarian" was barbarously coined to designate those who wished to oppose the spread of rationalism by a quickening of the Church of England. In 1841 Newman's "Tract No. XC." was condemned by the heads of houses in Oxford, and led to the definite organization of the High Church forces. (X.)

Tract Societies are agencies for the production and distribution, or the distribution only, of Christian literature, more especially in tract form. They vary in importance from the Society for Promoting Christian Knowledge (London), the Religious Tract Society (London) and the American Tract Society (New York)—all of which are publishing houses of recognized standing—to small and purely local organizations for distributing evangelistic and pastoral literature. It was not until the Evangelical Revival that tract work began to develop along its modern lines. Starting from the provision of simple evangelistic literature for home use, the enterprise grew into the provision of Christian literature, not only for home use, but also for the mission fields of the world. With this growth there proceeded another development, the production of books and magazines being added to that of tracts. The title "Tract Society" has, in fact, become misleading, as suggestive of limitations which had but a brief existence and are no longer recognized by the more important agencies. On the other hand it must not be supposed that because the work has gone beyond the provision of tracts, these are no longer widely employed. Probably their use in various forms at home was never wider than it is to-day; whilst in India, China and elsewhere the attack of the Christian tracts is being met by the circulation of vernacular tracts in defence of the non-Christian faiths.

The Society for Promoting Christian Knowledge, founded in 1698, though most widely known as a publishing agency, assists in a wide variety of ways the work of the Church of England. On its publication side, it is for its own Church both a Bible society and a tract society. Moreover, its publications include not only versions of the Holy Scriptures and of the Liturgy, but also theological and general literature in many forms. It has given much attention to providing good reading for children; whilst its tract catalogue is especially rich in works bearing on Christian evidences, Church seasons and the doctrines of the Anglican Church. To the foreign missions of the Church the S.P.C.K. has been a helper of the utmost value, more especially in regard to their medical missions and their use of Christian literature. In the latter case the help is given by grants of works produced either at home or by mission presses in the field. As early as 1720 it was using Arabic; but it has from time to time been of especial value in helping to found a Christian literature in languages or dialects just reduced to writing. Thus whilst recent publications for the mission field include works in Arabic, Chinese and Urdu, they also include publications in Addo, Lunyoro and Sgau Karen.

The Religious Tract Society, founded in 1799, and thus contemporary with the great missionary agencies and the Bible Society, is, like the last-named, an interdenominational organization. Its earliest publications were in English and were tracts. But it speedily undertook book publications and extended its field of operations. It began to provide tracts for China in 1813, and as early as 1817 an auxiliary tract society was founded at Bellary in India by some men of the 84th Regiment. In undertaking book publication, the society became one of the pioneers in the provision of sound and cheap literature; whilst by the issue of the *Sunday at Home*, the *Leisure Hour*, the *Boy's Own Paper*, the *Girl's Own Paper*, the *Cottager and Artisan* and other periodicals, it helped to lead the work in the provision of popular magazines. Like the S.P.C.K., the R.T.S. now produces general theological literature as well as tracts in a variety of forms, whilst it also gives especial attention to the provision of healthy reading matter for young people. Its grants of books and tracts are open to members of all Protestant denominations. The society aids Protestant communities on the Continent by maintaining depôts at Madrid, Barcelona, Lisbon, Vienna, Budapest and Warsaw; whilst it also assists, by grants, publication work in France, Italy, Russia, Turkey and Scandinavia. In the mission field it works mainly through subsidiary tract societies locally organized. The chief of these tract and book societies are in India carried on at Calcutta, Madras, Bombay, Bangalore, Allahabad and Lahore; in China at Peking, Shanghai, Hong Kong, Canton, Hankow, Chung-king and Mukden; and in Japan at Tokio. The literature produced by these organizations ranges from commentaries on the Holy Scriptures to the simplest tracts and leaflets. In 1908 the society opened a special fund in aid of its Chinese work, and by this means the provision of Christian literature in book and tract form for Chinese readers has been greatly extended. Much literature for various foreign fields is also produced in Great Britain and distributed from the society's headquarters. As with the S.P.C.K., the R.T.S. has been of great service in providing (next to the Holy Scriptures) the earliest literature for some languages. Thus it has helped to provide tracts for the Miaos of west China and for the Baganda, together with the *Pilgrim's Progress* in Bemba and in Ewé, two little-known African tongues. The languages in which works produced or aided by the society have appeared number about 300. In the distribution of its grants of tracts for home work nearly all the great evangelical organizations have a share. In the administration of a subsidiary tract society all the evangelical agencies at work in its field are as a rule represented.

In addition to the work of these societies, the production and distribution of tracts at home is carried on by *The Stirling Tract Enterprise*, which also sends grants of its publications to India, Ceylon and Africa; by *The Children's Special Service Mission*, which also issues publications in Chinese, Japanese and some Indian languages; and by *The Scripture Gift Mission*, which sends its publications into China and the East generally. In the mission field *The Christian Literature Society for India* (formerly the Christian Vernacular Educational Society), established in 1858, has its headquarters in London with auxiliary committees in India and Ceylon. It will always be associated with the name of Dr John Murdoch (d. Aug. 10, 1904), its secretary for nearly half a century. It works on similar lines to the tract societies, but includes a wider range of educational literature, in the provision of which it has been especially helpful to the mission schools of India.

The Christian Literature Society for China (formerly the Society for the Diffusion of Literature and General Knowledge among the Chinese) is incorporated (1909) in Shanghai, but has an advisory committee and an executive committee in London. It has been of great service in approaching the official and upper classes of China by its magazines and books, as well as by the diffusion of more popular literature.

The American Tract Society (New York) works, both in regard to domestic and foreign enterprises, upon similar lines to those of the Religious Tract Society. Upper Canada has its tract society also and similar organizations exist on the continent of Europe.

(A. R. B.)

TRACTION (Lat. *trahere*, to draw), the act of drawing or hauling. As used in this article the term refers to the methods of employing animal and mechanical power for transporting persons or things from place to place in wheeled vehicles.

Animal Traction.—The oldest form of motive power is that of animals, those most commonly employed for draught purposes on ordinary roads being horses, mules, donkeys and oxen. On the continent of Europe dogs are often harnessed to light carts or barrows, but in England their use in this way was prohibited by the Cruelty to Animals Act of 1854. Camels and elephants are only rarely used as draught animals in special circumstances.

When men and animals carry burdens, or draw or propel loads in certain vehicles, it is difficult, and sometimes impossible, to determine the duty performed in foot-pounds of work, because of the uncertainty of the amount in pounds of the resistance overcome. In this case, for the purpose of comparing performances of the same kind with each other, a unit is employed called a *foot-pound of horizontal transport*, meaning the conveying of a load of 1 ℔ 1 ft. horizontally. The following table, given by W. J. Macquorn Rankine, gives some examples of the daily duty of men and horses in units of horizontal transport, L denoting the load in ℔, V the velocity in feet per second, and T the number of seconds per day of working:—

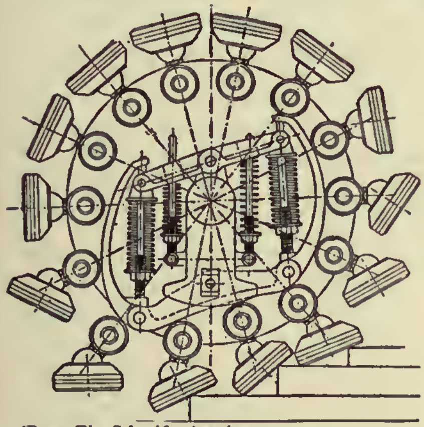
	L.	V.	$\frac{T}{3600}$.	LV.	LVT.
	℔.	Feet per second.	Hours per day.	℔. conveyed 1 ft.	℔. conveyed 1 ft.
MAN—					
Walking unloaded, transport of own weight	140	5·0	10	700	25,200,000
Do. do.	140	6·0	10	840	30,240,000
Wheeling load L in two-wheeled barrow, returning empty; V = ½ velocity	224	1·6	10	373	13,428,000
Do. one-wheeled barrow, do.	135	1·6	10	225	8,100,000
Travelling with burden	90	2·5	7	225	5,670,000
Conveying burden, returning unloaded	140	1·6	6	233	5,032,800
Carrying burden for 30 seconds only	252	—	—	—	—
	126	11·7	—	1474·2	—
	—	23·1	—	—	—
HORSE—					
Walking with cart always loaded	1500	3·6	10	5400	194,400,000
Trotting do. do.	750	7·2	4½	5400	87,480,000
Walking with cart, going loaded, returning empty; V = ½ mean velocity	1500	2·0	10	3000	108,000,000
Carrying burden, walking	270	3·6	10	972	34,992,000
Do. trotting	180	7·2	7	1296	32,659,200

For tramway service, horse, or occasionally mule, traction was formerly employed almost universally, but on account of limited speed and high cost it has been generally abandoned, except in a few localities, where the smallness of the line, low value of livestock, labour and feed, and long headway intervals, make it still profitable.

The tractive force required on a straight and level tramway is found to vary from $\frac{1}{150}$ to $\frac{1}{50}$ of the load, according to the condition of the rails. On a tramway having grooved rails in average condition it is about $\frac{1}{100}$. The resistance is thus, at the best, nearly double that on a railway, and sometimes as much as on a good paved road. This is due to the friction of the flange of the wheel in the grooved rail, and to the fact that the latter is always more or less clogged with dirt. The clearance between the flange and the groove is necessarily small, as the former must have sufficient strength, and the latter must be narrow. The least inaccuracy of gauge, therefore, causes extra friction, which is greatly increased on curves. By removing the flanges from two of the four wheels of the tramway car H. E. Tresca (1814–1885) found that the resistance was reduced from $\frac{1}{100}$ to $\frac{1}{148}$ of the load. The resistance due to gravity is of course not lessened on a tramway; and if $\frac{1}{100}$ of the load be the tractive force required on the level, twice as much, or $\frac{1}{50}$ of the load, will be required on a gradient of 1 in 100 and three times as much on a gradient of 1 in 50. To start a tramcar, four or five times as great a pull is required as will keep it in motion afterwards, and the constant starting after stoppages, especially on inclines, is destructive to horses. Horses employed on tramways are worked only a few hours a day, a day's work being a journey of 10 or 12 m., and much less on steep gradients. In London a tramcar horse bought at the age of five years had to be sold at a low price after about four years' work. On the Edinburgh tramways, in consequence of steep gradients, the horses lasted a less time, and had to be constantly shifted from steep to easier gradients. The cost of traction by horses is generally 6d. or 7d. per mile for two horses, and more when the gradients are steep (see also TRAMWAY).

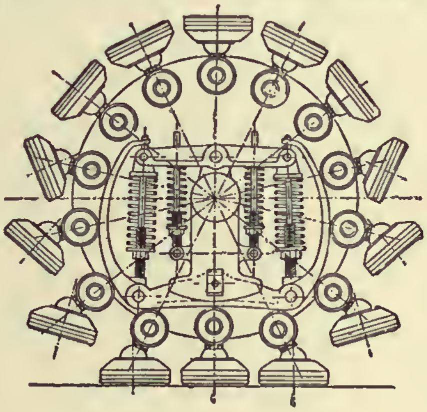
Steam Traction.—The most universally used form of motive power is the steam engine, which has been constructed to work on ordinary roads, on tramways and on railways. The road or traction engine comprises a boiler mounted on wheels, and a steam engine usually placed on top of the boiler. The front axle is pivoted so that it may be moved by means of a steering wheel geared to it, and the rear wheels are geared to the engine. The wheel rims are made wide to prevent them from sinking in loose earth or muddy roads. The whole arrangement is similar to the ordinary wheeled portable boiler and engine with the addition of the steering wheel and a gear connexion from the engine to the rear wheels. The tractive power of these engines is high, but their speed low—usually 4 to 6 m. per hour.

A peculiar form of road motor is made by equipping the axles of a traction engine with the so-called "Pedrail" invented by B. J. Diplock. This is an arrangement whereby circular pads or "feet," fastened around the periphery of a wheel, come successively in contact with the ground, the motion approximating to a smooth, even stepping or walking along. Fourteen of these feet are placed



(From *The Scientific American.*)

Position of the parts in overcoming obstacles.



Position of the parts on a level road.

FIG. 1.—Principle of the Pedrail's operation.

around a wheel, and each is attached at the end of a spoke, free to slide radially toward and from the hub of the wheel. Each spoke has fastened to it a helical spring which tends to draw it inwards. On each spoke there is also a roller, which bears against a cam-shaped piece placed inside the periphery of the wheel. The engine is suspended by springs from the cam and is supported by it. The lower edge of the cam is practically straight and horizontal, the length of this straight portion being great enough to subtend an angle equal to the spacing of three spokes, or about 70°. By this means three of the feet are always resting on the roadway and support the engine, which really slides along on the rollers that are at any instant underneath the flat portion of the cam. The feet take successive positions on the ground as the movement of the engine proceeds, and the engine itself rolls along on the rail portion of the cam which rests on the rollers beneath it. Ball and socket joints are used to connect the feet to the spokes so that they may rest on any conformation they may encounter. This machine has shown a remarkable ability to pass over obstacles and rough roads, and even to climb roadless hills. It gives a maximum of adhesion of the drivers, and it is claimed that it will pass over rough roads with the expenditure of less energy than will an ordinary wheeled traction engine. Its speed is necessarily low—about 4 m. per hour.

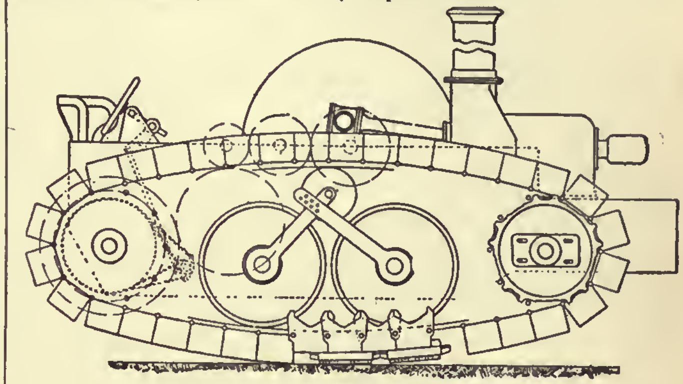


FIG. 2.—Chain Track Tractor.

The Hornsby "Chain Track Tractor" (fig. 2), patented by Mr David Roberts, is provided with two endless chains, one on each side, which constitute the track on which the machine travels. Each chain is carried on two sprocket wheels, placed at the extreme

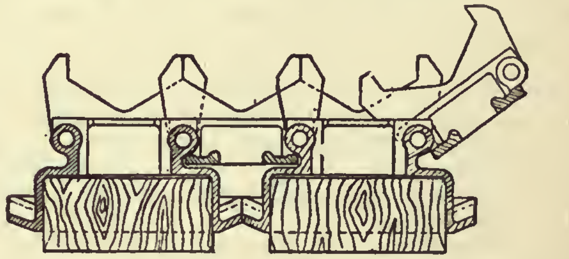

FIG. 3.—Links of Chain Track.

ends of the frame, and is formed of a number of links (fig. 3) so connected that it is free to bend in one direction, as required to pass round the sprocket wheels, but is locked into a rigid bar by pressure acting in the opposite direction. On their outer surfaces these links bear pads or feet, while their inner surfaces compose a track upon which roll the middle or weight-bearing wheels. Power applied to one of the sprocket wheels exerts a pull on the chain, but this being held fast by the weight of the engine pressing the feet to the ground, the effect is to roll the engine along the track, and as this happens the feet at the rear end are one by one lifted off the ground, carried round the sprocket wheels, and relaid at the front of the machine. This construction not only renders the whole weight available for adhesion, but also provides a long supporting base and thus enables the machine to pass over soft ground, loose sand, morasses, &c., in which an ordinary traction engine would certainly sink. Steering is effected by retarding or stopping the motion of the sprocket wheels on the side towards which it is desired to turn.

For tramway work steam is scarcely used at all now, though small locomotives—usually having their engines geared to the driving-wheels, instead of the connecting-rods being coupled direct to them—have been used in the past for this work. They were compactly designed and equipped with mufflers to deaden the sound of the exhaust, with other devices to decrease noise and smoke. In some instances, the engine and boiler were placed in the forward end of a car, a partition separating them from the main body of the car in which the passengers were carried.

For description of steam railway engines see RAILWAYS: *Locomotive Power*, and STEAM ENGINE.

Fireless Engines.—Fireless engines were first tried in New Orleans, and were in successful use on tramways in France and

Batavia, Java, for some years. The motive power was obtained from water heated under pressure to a very high temperature in stationary boilers and carried in a reservoir on the engine, where it gave off steam as the pressure and temperature were reduced. Two tons of water heated to give a steam-pressure of 250 ℔ to the square inch served for a run of 8 or 10 m., more than $\frac{9}{10}$ of the water and a pressure of 20 to 25 ℔ above the atmosphere being left on returning to the boiler station. Large boiler-power was required to reheat the engine reservoirs quickly, and this could be afforded for only a few engines; but, when worked on a sufficient scale, the fireless engines were claimed to be economical, the economy resulting from the generation of the steam in large stationary boilers.

Compressed Air.—Compressed air as a motive power offers the advantage of having neither steam nor the products of combustion to be got rid of. In W. D. Scott Moncrieff's engine, which was tried on the Vale of Clyde tramways in 1876, air was compressed to 310 ℔ per sq. in., and expanded in the cylinders from a uniform working pressure to that of the atmosphere. There is a considerable loss of heat during the expansion of the air which is attended with a serious loss of pressure, and in L. Mekarski's system, which was in use for the propulsion of tramcars at Nantes for a number of years, the loss of pressure was considerably lessened by heating the air during expansion. The air, at a pressure of 426 ℔ per sq. in., was stored in cylindrical reservoirs beneath the car, and before use was passed through a vessel three-quarters full of water heated to 300° F., by which it was heated and mixed with steam. The heat of the latter was absorbed by the air during its expansion, first to a working pressure which could be regulated by the driver, and then to atmospheric pressure in the cylinders. At Nantes the average cost for three years of propelling a car holding thirty-four persons was about 6d. per mile. Owing to the heat losses in compressing the air, and other considerable losses incident to its use, the compressed-air systems of traction have been found inefficient and have nearly all been replaced by the more flexible and efficient electric motor.

Cable Traction.—Moving steel cables, propelled by steam engines, have been used for traction. The street railway cars running from New York to Brooklyn, over the Brooklyn Bridge, were for many years propelled by a cable to or from which the cars could be attached or detached at will, and, though electric motors are now used on this line, the cables are still kept in place as a reserve in case of breakdown of the electrical system, and are used whenever an accident to the electrical plant occurs. Before the advent of electric traction, the tramways using cable propulsion were numerous and of great size, as at San Francisco, Chicago, Washington, Baltimore, Philadelphia and New York in America, at Highgate Hill (London) and Edinburgh in the United Kingdom, and at Melbourne in Australia. The Glasgow Subway is so equipped.

In the usual form, the motive power is transmitted from a stationary engine by a rope of steel wire running always in one direction, up one track and down the other, in a tube midway between the rails, on pulleys (fig. 4) which are arranged so as to suit curves and changes of gradient as well as straight and level lines. Over the rope is a slot $\frac{3}{4}$ in. wide, in which travels a flat arm of steel connecting the dummy car with the gripper (fig. 5) which grasps the cable. The flat arm is in three pieces, the two outer ones constituting a frame which carries the lower jaw of the gripper, with grooved rollers at each end of it, over which the cable runs when the gripper is not in action. The upper jaw is carried by the middle piece which slides within the outer frame, and can be depressed by a lever or screw, pressing the cable first on the rollers and then on the lower jaw until it is firmly held. The speed of the cable, which is generally 8 to 10 m. an hour, is thus imparted to the car gradually and without jerk. The arrangements for passing the pulleys, for changing the dummy and cars from one line to the other at the end of the road, for keeping the cable uniformly taut, and for crossings and junctions with other lines, are of considerable ingenuity. When the cars are cast off from the cable they must be stopped by hand brakes which, on steep gradients especially, must be of great power.

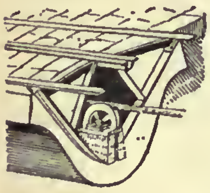

Fig. 4.—Cross-section of Cable Road.

Gasolene Engine Traction.—Explosive engines using gasolene (petrol) have been used for motive power, and this is the principal form employed in the road motor car. Certain railways in England and America have experimented with cars having a gasolene engine placed in one end to propel the car, the greater part of which is left clear for the accommodation of passengers. These cars are intended for short runs and may in effect be classed as belonging to extended tramway service. They have yielded encouraging results.

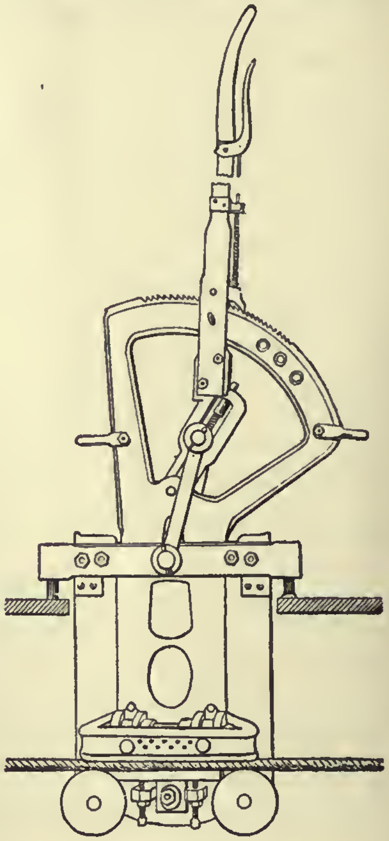

Fig. 5.—Gripper.

Electric Traction.—Electric traction, as treated here, will refer to the operation of vehicles for the transportation of passengers and goods upon tracks, as distinguished from what are known as telpherage systems on the one hand (see Conveyors), and automobiles intended to run on common roads on the other (see Motor Vehicles).

Possibly the first electric motor was that made by the Abbé Salvatore dal Negro in Italy in 1830. As early as 1835, Thomas Davenport, a blacksmith of Brandon, Vermont, U.S.A., constructed and exhibited an automobile electric car, operated by batteries carried upon it. Robert Davidson, of Aberdeen, Scotland, began experimenting about 1838 with the electric motor as a means of traction, and constructed a very powerful engine, weighing five tons and carrying a battery of forty cells. This locomotive made several successful trips on Scottish railways, but was finally wrecked by jealous employés of the railway while it was lying in the car sheds at Perth. In 1840 a provisional patent was granted in England to Henry Pinkus, which described a method of supplying electric energy to a moving train from fixed conductors. A little later, in 1845, French and Austrian patents granted to Major Alexander Bessolo described practically what is to-day the third-rail system. In 1847 Professor Moses G. Farmer, of Maine, U.S.A., built a model locomotive operated by electricity, which he exhibited at Dover, New Hampshire, and later at other places in New England. Shortly afterwards Professor C. G. Page, of the Smithsonian Institution in Washington, constructed an electric railway motor, which made a trip on the 29th of April 1851, from Washington, D.C., to Bladensburg, Maryland, over the Baltimore & Ohio railway. This machine carried 100 Grove's cells, and attained speeds as high as 19 m. an hour. Perhaps the beginning of modern electric traction may be said to date from 1879, when the firm of Siemens & Halske put in operation the first electric railway at the Industrial Exposition in Berlin. In America it was not until a year later that real work began and T. A. Edison built an experimental line near his laboratory in Menlo Park, New Jersey. In 1880 a locomotive driven by accumulators was constructed and operated at a linen-bleaching establishment at Breuil-en-Auge, in France; and in 1881 a similar car was worked upon the Vincennes tramway line. On the 12th of May 1881 the first commercial electric railway for regular service was opened for operations at Lichterfelde, in Germany. The first really noteworthy road was that constructed in 1883 at the Giant's Causeway at Portrush, in the north of Ireland. This line was 6 m. long, and the power was obtained from turbine wheels actuated by a cascade on the river Rush. The method of supply was, curiously enough, the third rail.

In 1883 invention in electric railways seems to have taken a decided advance in America. It was in this year that the conflicting interests of Edison and S. D. Field were consolidated; and at the same time C. J. van Depoele and Leo Daft began their experimental work, which later resulted in numerous commercial railways. Next year E. H. Bentley and Walter Knight opened to the public in Cleveland, Ohio, U.S.A., a railway operated by an open-slot conduit, and for the first time worked in competition with horse traction on regular street railway lines. For the next two years much experimental work was done, but it may be said with fairness that the first of the thoroughly modern systems, in which a large railway was equipped and operated under service conditions by electricity, was the line built in Richmond, Virginia, U.S.A., by Frank J. Sprague in 1887. This railway had 13 m. of track, and started with an equipment of forty cars. It has been in continuous and successful commercial operation ever since. The original Richmond system was in all its essential particulars the overhead trolley system now in use. Many improvements have been made in the construction of the motors, the controllers, the trolleys and the various details of car equipment and overhead construction, but the broad principles have not been departed from. The success of the Richmond line called the attention of tramway managers to the advantages of electricity as a motive power, and its substitution for other systems progressed with astonishing rapidity.

The pioneer application of electricity to heavy electric traction was that of the Baltimore & Ohio railway tunnel at Baltimore, Md., U.S.A., and the system was put into operation in 1895. This tunnel is about $1\frac{1}{2}$ m. in length and passes under the city of Baltimore. Its route made the expense of ventilation prohibitive, and the smoke and gases from the locomotives made the use of the tunnel impossible without ventilation. The management therefore decided to attempt the use of electric locomotives to haul the trains through, despite the fact that there existed no prior applications of heavy electric motors for even far lighter service than that demanded by the conditions, namely, the propulsion of trains of over 2000 tons up a grade of 42 ft. to the mile. The engineering work and designing of the locomotives were undertaken by Dr Louis Duncan. The locomotives weigh 96 tons and have worked successfully since they were first put into commission. The electric service has been extended 6 m. from the mouth of the tunnel, making a total haul of nearly 8 m. for these locomotives. In 1907 many heavy electric locomotives using continuous current were constructed for the New York Central & Hudson River Railroad Company to operate a distance of about 5 m. from the New York terminus, and others for practically the same service, but using single-phase alternating currents, were put in for the New York, New Haven & Hartford Railroad Company.

It has been fully demonstrated that electricity is superior to its competitors—horses and moving cables—for tramway work. It is cheaper and more flexible. The relative cost of operation varies with the local conditions, but a fair average estimate would be that cable lines cost 25% more to operate than electric, and horse lines 100% more. The increased speed of the electric cars and the comfort rendered possible by larger vehicles always increase the receipts when horse traction is replaced by electric, while the latter, as compared with the cable, allows better and easier control of the car and a much greater possible speed variation. The installation of an overhead electric line costs less than a cable system, though the expense of a conduit electric line is about the same. By the extension of the urban tramway systems into the suburbs and the construction of inter-urban lines, electricity has come into competition with steam. Here the conditions are different. For ordinary suburban service, the electric cars, running through the city streets and on the highways, cannot, in speed, compete with steam trains operated on private rights of way. The fact that they run more frequently and can take up passengers anywhere along the line gives them an advantage, and within limited distances they have taken a large proportion of suburban traffic from steam railways. For long-distance service, in order to compete with steam a speed much greater than that used on ordinary tram-lines must be adopted, while owing to the time spent on the car more attention must be paid to the comfort of the passenger. Speed and comfort being equal, the great advantage of electricity is that, when it is used, the most economical way of transporting a given number of passengers between two points is in a larger number of small trains; with steam the converse is true. A frequent service is a great attraction to passengers.

For freight service, especially on railways having heavy grades, electricity also possesses many advantages, due principally to the peculiarity of the electric locomotive, which admits of its maintaining its tractive effort or so-called "draw-bar pull" when running at relatively high speeds. This steam locomotives cannot do. Thus a steam locomotive weighing 100 tons may exert a draw-bar pull of say 45,000 lb at a speed of 6 m. per hour, while at 15 m. per hour the continuous draw-bar pull will not exceed about 25,000 lb. On the other hand, an electric locomotive weighing 75 tons and having a tractive effort of 34,000 lb at 6 m. per hour will exert a pull of about 27,000 lb at 25 m. per hour. From this it is clear that an electric locomotive may pull a heavier train at a fair speed than can a larger steam locomotive. This admits of more rapid movement of freight trains, and thus decreases the hauling cost. Another advantage the electric system has for freight service is the ability to couple several light locomotives in tandem, all under the control of one driver, and thus pull at a high speed larger trains than may now be drawn by steam locomotives of weights commercially admissible. Also, these lighter motors distribute the weight over the track instead of having it concentrated on a few wheels, and the heavy pounding due to the latter condition is obviated and the maintenance of the track and bridges reduced. Other savings arise from diminished fuel consumption, elimination of water and coal stations with their attendants, and greatly reduced repairs on motive power. The chief disadvantage is the stoppage of all trains on a section if the source of current supply should fail. With proper precautions in design and construction this should be a remote possibility, and since electric rail haulage, in any form attempted up to the present, has shown a reduced cost for a given service as compared with steam traction, it is not improbable that the future will witness great activity in the change from steam to electricity for long-distance railway work.

Systems of electric traction may be divided broadly into two classes, the one employing continuous, the other alternating currents to drive the motors. Both of these classes may be further divided with reference to the conducting system employed between the source of current and the motor. The system may also be divided according to operative units into three classes—the single car, the train pulled by one or more directly controlled locomotives or motor cars, and the train operated by two or more motor cars under a common secondary control. This last is called the "multiple unit system."

Continuous-Current Systems.—The applications of continuous current to electric traction comprise six principal varieties, with numerous modifications and combinations. In all of them the motors are operated under a constant, or approximately constant, potential difference. The system in which cars were connected in series by automatic switches, in limited use in the United States in 1888 and 1889, has now disappeared, and the parallel system of connexion, in which the cars are bridged across between the two conductors of a parallel system, maintained at a substantially constant voltage, has become practically universal.

Overhead Construction.

The overhead conductor and track-return construction is the standard for street railway work in most of the cities where electric traction is employed, though there are some notable exceptions. In its present development the system may be said to have grown out of the work of Sprague in Richmond in 1887. Over the track is suspended a bare wire, generally of hard-drawn copper, known as the trolley wire. The normal practice is to use a wire not less than 0·325 of an inch in diameter to assure permanence, since smaller wires wear out rapidly from the friction of the trolley and the burning of the surfaces of contact. The wire is usually of circular cross-section. Sometimes wires of other sections have been used, notably one having a cross-section similar to the figure 8, but the advantage of these forms is problematical, while the difficulty attending their proper installation is considerable. In some cases the working-conductor, or trolley wire, is suspended at one side of the track, connexion with it being made by a side-bearing trolley, but its usual place is directly over the track, as this arrangement leads to simpler and more efficient construction of the trolleys and their accessory parts. For certain special cases, where very large currents are employed, the overhead conductor is made of bar metal or structural shapes. In the Boston (Massachusetts) subway, where the traffic is very heavy, a bar of rectangular section is used, supported at frequent intervals from the roof. In the Baltimore & Ohio railway tunnel at Baltimore, Md., the steel working-conductor originally consisted of two Z bars forming a trough, the current being collected by an iron shoe, but this form has been replaced by a sectional third rail. But whatever the nature of the conductor, it is usually insufficient to carry the current necessary for the operation of the system without excessive loss. Recourse is therefore had to feeders or reinforcing conductors. These may be of any form, but are most frequently copper wires or cables of large section, connected at intervals of a few hundred feet to the working-conductor. They are sometimes carried on poles, but municipal ordinances frequently require their installation in underground conduits. In general, it is customary to divide the working-conductor into sections of from 1000 to 5000 ft. in length, insulated from one another and fed separately through manual or automatic cut-out switches, so that an accident causing a short-circuit or break in continuity on one section will not impair the operation of others.

In ordinary street railway construction two methods of suspending the trolley wire are in vogue. The most usual construction is to hang it from insulators attached to transverse wires running between pairs of poles set on opposite sides of the track. Bracket arms attached to poles are often used, especially on suburban lines; they are frequently double, or T-shaped, and placed between the two tracks of a double-track line. In the standard construction for either variety of suspension, the insulators are bell-shaped, and composed of some hard moulded or vitreous material. The trolley wire is supported by a clamp about 9 in. long, which embraces about three-quarters of its circumference. This clamp is usually made of bronze, and is now generally fastened to the trolley wire by a screw, causing the two parts of the clamp to close upon the wire as would the jaws of a vice, or is automatic, clamping the wire the more tightly as the strain upon it increases. It was formerly considered expedient to solder the wire into the clamp, but this practice is now generally abandoned. The insulating bell is so designed that its material is subjected only to compression stresses by the weight of the wire. It is provided at its upper part with a single catch for attachment to the transverse wire or to the bracket arm. If a span wire is used it is fastened to the poles, there being turnbuckles to tighten it, while a strain insulator on either side gives a double insulation between the trolley wire and the poles. With a bracket construction it was formerly the custom to attach the insulator directly to the bracket arm, but the blow of the trolley wheel broke great numbers of insulators, and it has therefore become the practice to adopt some more flexible method of attachment, a number of different forms being in use. The poles between which the span wires are stretched, or to which the bracket arms are attached, are of wood or iron. They are firmly set in the ground, usually with concrete.

Catenary Construction. Another form of overhead construction for high speed service, brought out by the Westinghouse Company and known as the "Catenary" system (fig. 6), is designed to hold the contact or trolley wire in a horizontal position above the track without any dip or sag. Essentially it is

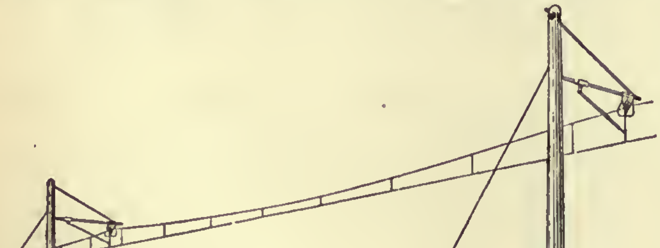

FIG. 6.—Single Catenary Line.

made up of a supporting cable made of stranded galvanized steel wire $\frac{7}{16}$ in. in diameter which is firmly fastened to brackets attached to the supporting poles and from which the trolley wire is suspended by means of rigid iron hangers spaced about 10 ft. apart. A proper sag is given the supporting cable, and the lengths of the hangers vary so that the trolley wire is held horizontal without sag. The construction resembles a single supporting cable and suspended chord of a suspension bridge. The trolley wire, the hangers and the suspension cable are all mechanically connected together and in metallic contact, so that the whole system acts as a conductor. The supporting cable is held by insulators at the points where it is supported on the brackets at the poles. For heavy work there the currents taken by the passing cars and locomotives are great, requiring a very large trolley wire, two supporting cables are strung from pole to pole and the trolley wire suspended below and between the two.

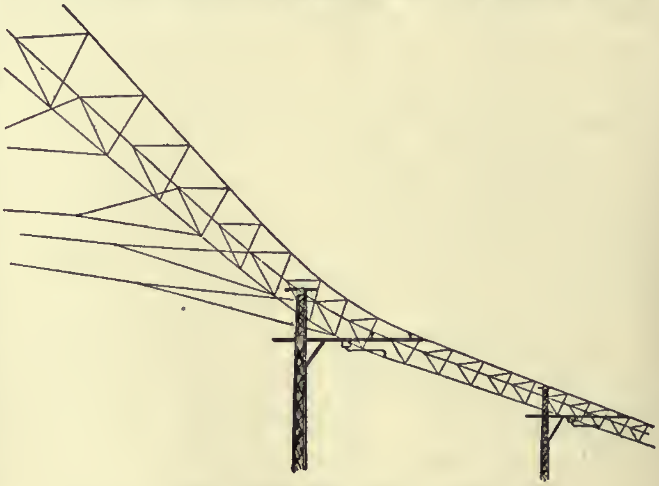

FIG. 7.—Double Catenary Line.

In this case the hangers are triangular in form and hung with the apex of the triangle downward. The two upper angles are fastened to the pair of supporting cables, while to the lower angle is attached the trolley wire. This arrangement is called the "double catenary" construction (fig. 7).

Rail Bonding. In order to provide a proper return path for the current, the track must be made electrically continuous. This is accomplished by bonding the individual lengths of rail together in some way, or by actually welding them together to form a continuous length. There are many types of rail-bonding. In most of them holes are drilled in the ends of adjacent rails, and a copper conductor inserted between them, its ends being in some way forced against the walls of the holes. In one type the bond is in the form of a hollow cylinder, the ends of which are inserted in the holes in the rails, a tapered steel pin being driven in so as to expand the cylinder out against the rail. In another form the end of the bond is a solid cylinder, which is upset by hydraulic pressure, forcing it against the rail. A semi-plastic amalgam of mercury has been used to give a contact between the adjacent rails and the fish-plate connecting them. The most usual practice is to use a short bond covered and protected by the fish-plates. Tracks used for a return circuit are cross-bonded at intervals. If the track return has too great an electrical resistance it is reinforced by conductors connected to it at intervals and extending back to the power-house. Neglect to provide a proper return circuit has often caused a great loss of energy, and, in many places, excessive electrolytic action on iron pipes, cable sheaths and other metallic bodies buried in the earth. The lightning arresters provided on overhead lines are placed on the poles at intervals determined by the location of the line.

Double Trolley. In a few places the municipal authorities, in order to avoid the disturbances on telephone lines due to the fluctuation of a trolley current, and the electrolysis of gas and water pipes which may arise from a grounded return, have required the erection of a double overhead system. In this each track has two trolley wires forming a complete metallic circuit. The largest system of this kind is in Cincinnati, Ohio, U.S.A., where there are over 225 m. of tram-lines. The system has the advantages to which it owes its existence, but the multiplicity of wires at crossings, right-angle turnouts and switches is so complicated that automatic switching cannot be attempted. The man in charge of the car removes the double trolley from the wires at such points, and replaces it when they are passed. The construction adopted, except in respect to the points mentioned, is practically similar to that already described for the track-return system.

Open-slot Conduit. A number of patents have been granted in various countries for electric traction systems in which one or both of the fixed conductors are installed in a conduit underground, communication being had with them by means of an open slot, into which projects a current-taking device of some nature carried by the car as it moves along. A system of this character was installed at Blackpool, England, in 1885, and later one was very successfully operated in Budapest. The first large and important installation of this character to be made was in Washington, D.C., U.S.A., where a considerable system of street railways was changed from horse operation to this new method. The success of this system, and of experiments made on Lenox Avenue, in New York City, led to the construction of many miles of railways of the conduit type in the latter city. It is also used extensively in London. (For details of the construction of the conduits, see TRAMWAY.) This system is much more expensive to install than the overhead trolley system, but experience has shown that it can be as economically operated. Most of the troubles that have occurred have been due to lack of experience, but on the whole they have not been more serious than those experienced with overhead systems.

Closed Conduit.

The great expense of the open conduit has led numerous inventors to bring out systems of operating electric railways by means of closed conduits or sectional third rails, in which the working-conductor is laid on the surface of the ground between the rails, and is connected with the source of current only as the car passes over each section. In this way the immediate section or portion of the working-conductor under the car is electrically active, but other sections are not, and all danger to the passage of street traffic is removed. Up to 1900, nearly one thousand patents for this type of street railway construction, known also as the "surface contact" system, had been granted by the United States patent office alone. So far the system has been introduced in but few places, but its performance has been more than promising, and it is thought that it will be more extensively adopted in the future. Among the more important railways at present equipped with it may be mentioned one in Paris, using the Diatto system, and one at Monte Carlo, where the Westinghouse system is installed. In both these the current is supplied by means of "buttons" or metallic disks laid flush with the surface of the street between the tracks, and connected through switches to a working-conductor. Under the car is installed a current-taking device in the shape of a long runner or skate, which runs over the buttons and is appropriately connected with a storage battery on the car, so that when it touches one of the buttons current is sent from the battery through a system of electro-magnets operating the switches which connect that particular button to the feeding system, and thus the runners are enabled to receive current for the operation of the motors on the car. The various systems differ in the method of connecting the contact rail or button with the live conductors; in some a magnet on the car works a mechanism to make the desired contact, in others a current from batteries on the car actuates a switch located near the track. (See TRAMWAY.)

Third-rail System.

The third-rail system, which is a development of the overhead trolley and track-return system, has been applied to several large and important railway installations, especially in the United States, and in the prolongation of the Orleans railway in Paris from the Place Valhubert to the new station at the Quai d'Orsay. Its name almost sufficiently indicates its method of operation. A rail similar to the track-rails is laid upon insulators and forms the working-conductor. On the elevated railways in New York, Brooklyn, Boston and Chicago and the subway in New York, a pressure of about 600 volts is used between this rail and the track-rails which form the return circuit. Contact is made with the third rail by means of a bronze or cast-iron shoe, either resting upon the rail by its own weight, or pressed down upon it by springs. This is generally attached to some part of the truck of the car in preference to any part of the body of the car, so as to avoid any vibration or swaying due to the movement of the body upon its springs. The third-rail system has been adopted in many instances where large and powerful trains are to be operated on private rights of way, but it is nowhere in use for electric traction upon highways or in streets where there is any passing of foot passengers or vehicles. An excellent example of such construction may be found in the Albany & Hudson railroad, which connects the city of Albany with the city of Hudson, in New York state. Here the length of the road is about 32 m., the track being of standard gauge and laid with a 60-lb T-rail. A T-rail of the same size, raised about 1 ft. above the level of the running-rails, is used for the electrical conductor, and is installed on insulators situated 5 ft. apart on the ends of the cross-ties. All these rails are well bonded with copper bonds at the joints. At road crossings, which on this railroad are at grade, the third rail is omitted for a distance nearly equal to the length of a train. Appropriate cast-iron shoes, fixed to the trucks of the front and rear cars of a train, bridge the space, so that the forward shoes are running on the rail past the break before the rear shoes leave it. Upon this railroad motors of considerable size and power are used, and both passengers and freight in their original cars, as received from connecting steam railways, are transported. Other examples of third-rail construction occur in the extension of the Baltimore & Ohio railway tunnel at Baltimore, the New York Central Railway Company's New York terminal, the underground systems of the City & South London railway, the Waterloo & City railway, and the Central London railway in London, and the Versailles division of the Western railway of France. In some cases, as on the Metropolitan, the District, and several of the "tube" railways in London, the running-rails are not used for the return circuit, which is completed by a fourth rail similar to the conductor rail, laid outside the track.

Accumulators.

One of the oldest forms of electric traction is by accumulators. In brief, its principle is that storage batteries, or accumulators, are carried on the car, which becomes a veritable automobile. It has been the usual practice to instal about 80 cells, giving a pressure of 160 to 175 volts at the motors; these are recharged after the car has run about 25 m. In general, the accumulators are not charged in place, but the car is supplied with a new set, fully charged, at the end of a run of about the length mentioned. The system has been installed in a very large number of places in Europe and America, but has never shown the gratifying commercial success which the direct-conduction systems exhibit, on account of the high cost and depreciation of storage batteries. In some places, notably in Hanover, Germany, where legislative ordinances have forbidden the overhead conducting system in city streets, a combination has been used whereby accumulator cars run in the city districts from the energy stored in their batteries, and in the suburbs operate directly as overhead trolley cars, the batteries being charged at the same time from the overhead system.

Polyphase.

Alternating Current Systems.—Alternating current systems are now being used, both single-phase and three-phase. In the former case the newly-developed single-phase motors, later to be described, are employed, while with three-phase systems induction motors are used. The polyphase current is much used as a means of distributing energy from a central power-station over extended lines of railways, but is generally converted into direct current through the agency of rotary converters, and fed to the lines as such. There are, however, a few railways working directly with induction motors upon a three-phase system of supply. Prominent among these may be mentioned the Valtellina railway in Italy and the Jungfrau railway in Switzerland. Upon these lines the rails are used as one of the three conductors, and two trolley wires are suspended above the track. The locomotive is provided with two trolleys, one running upon each wire, and consists simply of an induction motor coupled through appropriate gearing to the mechanism of the truck. For starting a large resistance is introduced into the rotor or secondary circuit of the motors by means of collecting rings placed on its shaft, upon which bear brushes. This resistance is cut out as the speed increases, until it is all withdrawn and the rotor is short-circuited, when full speed is attained. It has been found that potential differences of about 500 volts in each phase can be safely handled, and it is claimed that the few railways which use polyphase currents have shown gratifying results in practice.

Single-phase.

In the early years of the 20th century single-phase alternating current motors for electric traction were developed, and single-phase systems were extensively installed both in Europe and in America. The simplest type of single-phase motor is a series motor provided with the usual commutator and brushes, in which the current passes through both the field coils and the armature coils. The armature and field windings being traversed by the same current, the reversal of the field magnetization and that of the direction of current flow in the armature are coincident, so that the turning effort or torque, on the armature current produced by the interaction of armature and field magnetization is always in the same direction. Since the alternating current passes through both members of the motor, the armature and field cores are both laminated. In the later types of these motors the field coils are distributed and embedded in the field ring, so that the inner surface of the field ring presents a practically smooth surface to the armature. Troubles were at first experienced with commutation of the heavy alternating currents required for the operation of these motors, vicious sparking taking place at the brushes. This was overcome by the use of auxiliary or "compensating" coils, which are embedded in the field magnet ring, being placed between successive magnet coils. These compensating coils are usually connected in series with the main armature and field circuit. They may each, however, have their two ends joined together, (short-circuited), the currents in them being induced by the alternating magnetic flux of the fields.

Motors of the above types have the general characteristics of direct current series motors, and possess the same general relations between speed and torque that are such an important element in the success of direct current series motors. The efficiency of alternating current motors is not quite so good as that of direct current motors, on account of the rapid reversal of the iron magnetization in the field magnets, but their efficiency is high and their performance in practical work has been excellent (fig. 8).

There is another type of single-phase motor that has been used in Europe, but not in America, which is commonly called the repulsion motor. In these motors the armature is not directly included in the main circuit, but opposite points on the commutator are connected together through brushes. The working current is fed to the field magnets, and the rapid reversals of magnetization induce currents in the armature coils, which currents, working with the field magnetization, cause rotation. Several types of repulsion motors have been developed, and in general their characteristics are similar to those of the plain series type. They have not, however, come into extended commercial use. Single-phase motors for a given power are much larger, heavier and more expensive than the ordinary direct current motors, owing to the low magnetic densities at which the iron is worked. The power factor is between 0·75 and 0·85.

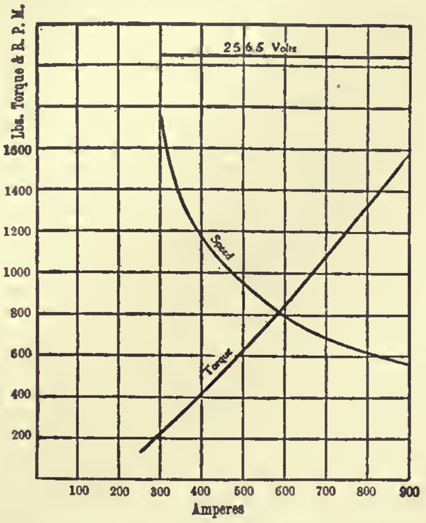

FIG. 8.—Characteristics of Series Single-phase Motor.

The advantages of the single-phase alternating system lie in the fact that it combines the simplicity of the overhead direct current construction with the possibility of exceedingly high voltage. Where heavy traffic is to be handled, and especially where that traffic is scattered, a direct current system, which up to the present has been limited in its voltage, is not commercially possible, as the amount of copper used for distribution and the excessive amount of apparatus required to convert high tension alternating current into low tension direct current, would make the cost prohibitive. In direct current

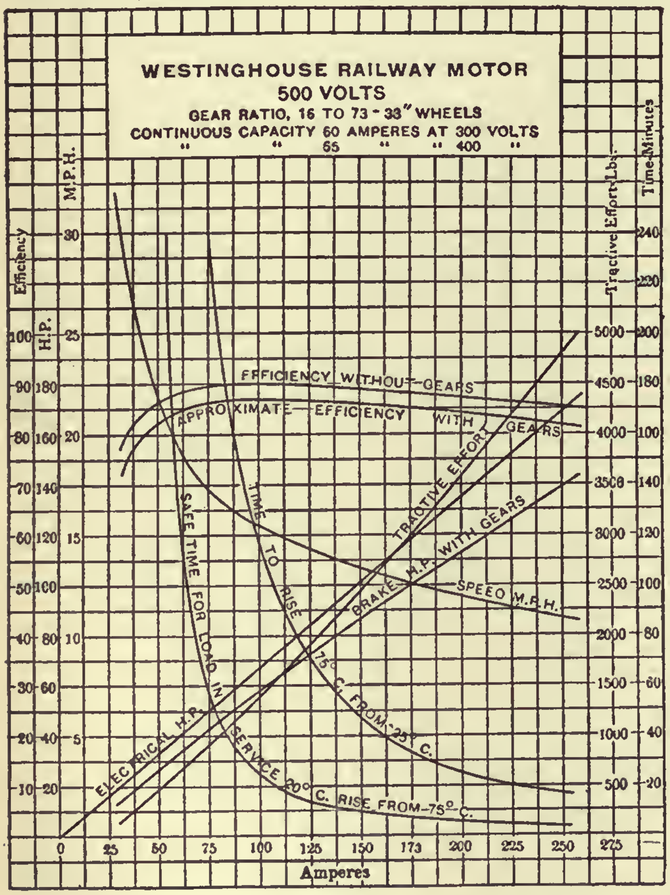

FIG. 9.

systems for lines of any length, it is the custom to use alternating current of high potential and to reduce it to direct current of low potential at different points along the line. This involves rotary converters, which by their nature require attendance in the sub-stations, while if the traffic is scattered so that the load on the sub-stations may at times be zero, and at other times may be very large, the capacity of the sub-stations must be equal to handling a maximum load, so that the total capacity of each sub-station would be based on the maximum instead of on an average condition. With the single-phase alternating current system, on the contrary, only static transformers in sub-stations along the line are required, and with the high voltages available (voltages as high as 11,000 volts are used at present) the distances between these sub-stations can be greatly increased as compared with the direct current sub-stations, so that each sub-station feeding a much longer portion of the line would have a better average load than in the direct current case. The static transformers do not require attendance, and their efficiency is much higher than that of the rotary converters.

Motors. Electric motors for traction purposes have been highly elaborated and developed. At first they drove the car axles through belts or sprocket chains, the motor being sometimes attached to the car, sometimes to the truck. At Richmond, however, in 1887, the Sprague method of communicating the power from the motor axle to the car axle was put into practical operation, and this has with slight modifications been retained. It consists of sleeving one end of the motor on the axle, suspending the other

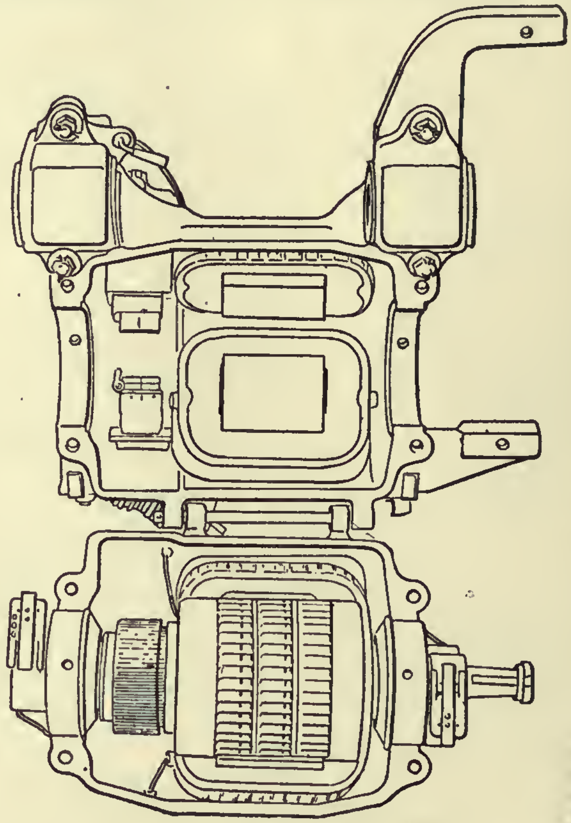

FIG. 10.—Standard Railway Motor.

flexibly from the car body or truck, and driving from the armature through spur gearing. At first the motors were too small for the work demanded of them. Their high speed required a double reduction in gearing, their overheating caused continual burn-outs, and the sparking at the commutators necessitated constant repairs. These defects were gradually eliminated. The motors were made larger, the quality of the iron and insulation was greatly improved, and finally a four-pole motor requiring only a single-speed reduction by spur-gearing was produced. Since that time further improvements in material and design have been introduced, and the present motor has been evolved. Almost all the standard modern traction motors are of the same general design. They are series wound, *i.e.* the same current passes through both the armature and the fields. This gives a strong starting torque or tractive effort, the torque diminishing as the speed increases. This characteristic is particularly suitable for traction. Fig. 9 shows the relation between speed and tractive effort of a standard railway motor of large size and power. The armature is built up of carefully tested iron disks, which are deeply slotted to make room for the coils. These are wound and insulated separately, and placed in the slots in the armature core; sometimes they are held in place by binding wire, sometimes by wedges. The commutator is put in place, the coil connexions soldered to it, and the proper end-coverings put on. The magnet frame is made in two parts, of cast steel, enclosing the entire armature. A lid in the top casting gives access to the brushes, which are of carbon. The field coils are wound on forms and properly insulated. When in operation it is practically water and dust proof, and with proper attention is a very durable piece of machinery (fig. 10). Although the standard design of motors is at present based on a single-reduction gearing, there are in operation traction-motors which are not geared.

On the locomotives used on the New York Central, the New York, New Haven & Hartford, and the Baltimore & Ohio railways in America, the City & South London railway in England, the armatures surround the driving axles. In all the cases mentioned, except the Baltimore & Ohio railway, the armatures are set directly on and solid with the axles of the driving-wheels, while on the Baltimore & Ohio locomotives the motors are sleeved on the axles, there being a slight play between the sleeve and the axle, which allows a flexible support. The wheels are driven by arms projecting from the armature shaft.

There is no fixed method of rating the output of traction-motors. Most manufacturers, in giving a certain horse-power capacity, mean that at the given rating the motor will run an hour with a rise in temperature of a certain number of degrees, not that it can be run continuously at the power given. Another system of rating depends on the draw-bar pull which the motor can develop under normal conditions of voltage and speed. Uniformity is greatly needed.

Controllers. One of the most important parts of the equipment of an electric car or locomotive is the controlling device. In the early days of electric traction a number of different methods of regulating the speeds of the cars were used, but they have been reduced to practically one standard method. In the old Sprague system there were at first no resistances outside of the motors themselves, but the field coils of the motors were divided into sections, and by changing the relative connexions of these sections the total resistance of the circuit could be changed; at the same time the strength of the field for a given total current was either increased

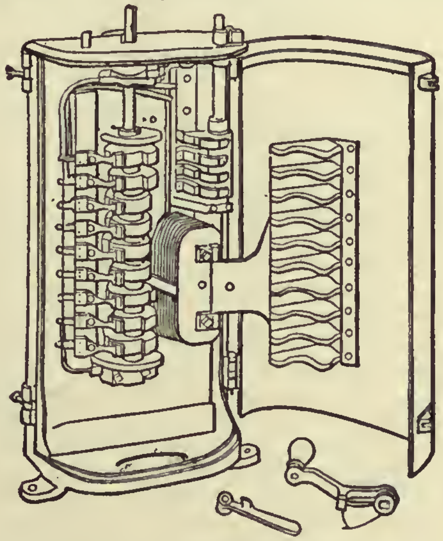

FIG. 11.—Controller (open).

or decreased. In other systems the fields and armatures of the motors were not changed in their relation to one another, but external resistances were cut out and in by the controller. Usually there are two motors on each car, and it is evident that if the speed of a car be changed within wide limits, all the other factors remaining constant, there will be a very considerable loss by either of these methods of regulating, unless the relative connexions of the motor armatures can be changed. This can be done by putting the two motors in series where low speed is desired, and in parallel where the speed is to be increased. This method was tried in the early days of electric traction at Richmond, and discarded, but it has been again taken up, and is now the standard method of regulation in ordinary tramway work. Roughly speaking, when the car is started the controller connects the two motors in series with an external resistance, then cuts out the external resistance, then breaks the circuit, then connects the two motors in parallel. The external resistance is put again in series with them, and then is gradually cut out as the car speed increases. By this method a considerable range of speed is attained at a fair efficiency. The controller (fig. 11) consists of a cylinder having on it a number of copper segments so arranged that on rotating it different connexions are made between stationary fingers that bear on these segments. In the first types much difficulty was experienced from the burning of the segments and fingers, due to the sparking on breaking the circuit, but this has been to a large extent obviated by using magnetic blow-outs at the point of break. (A magnetic blow-out is simply a magnet so arranged that the arc caused by breaking the circuit takes place in the magnetic field.) There is a reversing lever on the controllers separate from the controller handle, and interlocking with the controller so that the reverse lever may not be moved except when the controller is in the "off" position.

When it is desired to run trains of cars and to accelerate them rapidly, it is sometimes necessary to have more than one car equipped with motors. In this case all the motors must be controlled from one point, and a number of ingenious devices have been evolved to accomplish such "multiple control." In general, each car has its own controller, and all the controllers are operated by electric power from switches on each platform of any of the motor cars.

Regenerative Control. A motor and controlling system designed to save and utilize the power produced by a car running down an incline has been developed and is termed the "regenerative system." A car running over a line having heavy grades must have sufficient energy given to it to overcome its frictional resistance to motion and also to lift the weight of car and load from the bottom to top of each up-grade. On the return trip, the car "coasts" or runs down the grade without the consumption of current, but is restrained from attaining too high a speed by the brakes, thus wasting the energy existing by reason of the position of the car.

With the regenerative system the motors are caused to act as dynamos which are driven by the motion of the car axles when descending a grade, and, as they are connected to the line by the trolley or contacting device, the current thus generated is fed to the line and may assist other cars climbing grades at some other point on the system. The delivery of electrical energy also puts a resistance on the car axles and produces a braking effect which almost automatically fixes the car speed. If the speed be too high, the excessive current generated will tend to retard the car and reduce its velocity, while if too low the small current produced will set up but little opposition to motion and the car will accelerate.

Obviously, series motors cannot be used for this service. The motors have shunt fields, and their speed is varied by varying the field strength. Motors of this type are larger, more costly and slightly less efficient than series machines, so that a regenerative system has no place on roads that have a fairly level contour. When, however, the grades are frequent and excessive, the power saved more than counterbalances these factors, and the system may prove a valuable one for such service.

Brakes. For tramcars of ordinary sizes hand-brakes are used, these being generally spindle brakes. with leverage enough to handle the comparatively heavy cars. When the size and speed of the car increases, however, these hand-brakes do not give sufficient control, and power brakes have to be adopted. Of these there are several forms that have proved successful in practice. The one most extensively used in electric railways is the air-brake, which is similar in its mechanical operation to the air-brake used on steam railways. The compressed air required for the operation of the brake is obtained by means of an air-pump driven by an electric motor, the circuit of which is controlled by a switch actuated by the pressure of the air in the receiving tank. When this pressure rises to a predetermined value, the device acts and interrupts the supply of current to the motor, which is thus stopped. When the pressure falls below a determined minimum the device operates in the opposite direction, and the motor and pump start. Of electric brakes there are several varieties. One type consists of two iron disks, one keyed on the axle but capable of moving along it a short distance axially, and the other held firmly on the frame of the truck. By means of a coil, set in a recess of annular form turned in the face of the fixed disk, the disks are magnetized transversely, and are drawn together with greater or less pressure, dependent on the amount of current that is allowed to pass through the coil. It is customary to arrange the current connexions in this form of electric brake so that when the handle of the controller is turned beyond the stopping position the current is cut off from the source of supply, and the motor running as a dynamo furnishes the current to work the brake.

The magnetic track-brake, which is sometimes used on tramway cars, consists of a pair of steel shoes, suspended from the truck frame and hanging near and over the rail, a steel yoke connecting the two shoes together. On this yoke is wound a heavy magnetizing coil which, when energized, strongly magnetizes the two steel shoes and causes them to draw against and adhere to the track. Bracing links connect these track shoes with brake shoes on the wheel rims, and the drag of the track shoes thus applies pressure also to the wheel shoes. The downward pull of the track shoes gives a greater pressure of the wheels against the track than that due to the weight of the car, and the sliding or "skidding" of wheels, with the consequent production of flats, is avoided. A further braking effect comes from the use of the motors as dynamos, driven by the motion of the car, to supply current to the brake magnetizing coils. This therefore is one of the most effective brakes that has been devised. It has, however, not been very extensively used owing to its high cost and difficulties that arise from the track shoes running so close to the rails that any uneven places—frogs, switches, crossings and the like—may rub against them and give a braking effect at times when the car is accelerating or running. A pair of shoes is applied on both sides of the car, one pair being hung over either rail.

Another method of braking is by arranging the connexions of the two motors so that one acts as a dynamo driven by the motion of the car and supplies current to the other, which works as a motor, tending to turn the wheels in the direction opposite to that in which the car is moving. The production of current by the one motor and the reverse effort of the other give a powerful braking effect. The proper connexions are made by constructing the controllers with contacts additional to those required for motor control, which connect the machines in the desired manner when the controller handle is moved round past the "off" position.

Automatic brakes are always preferable to hand-brakes even though they cost much more, because the energy required to propel an ordinary tramcar is from 10 to 25 % more with hand than with automatic brakes. The cause is the constant pressure of the brake shoes of a hand brake against the wheel rims, the shoes being so held by the operator to avoid having too long a hand movement in applying the brake. The maximum pressure possible for any brake should be about 90 % of the weight of the car on the braked wheels. Less than this amount will give an inefficient brake; more will produce sliding or "skidding" of the wheels, producing "flats" on them, and also causing loss of retarding effect.

Of the numerous accessories necessary in the operation of electric railways one of the most important is the trolley. For an overhead system this consists in general of a metallic rod or tube mounted upon the top of the car and pressed upward against the trolley wire by springs. At the upper end of this trolley pole is generally placed a bronze wheel which runs along the under surface of the wire. On the continent of Europe considerable use has been made of bow-trolleys, which consist of light metallic bow-shaped structures, sustained in place by springs and running along on the under side of the wire against which they rub. The designs patented for trolleys are almost innumerable. Besides the trolleys, cars are ordinarily equipped with switches which are used to break the trolley circuit, with fuses or automatic circuit-breakers, with electric lamps, with lightning arresters, and with the necessary car wiring. The fuses or automatic circuit-breakers guard against an excess of current being passed through the motors, and when they are fitted the ordinary platform switch can be dispensed with. These automatic breakers can be set for any desired current.

Accessories.

The question of the generation and the distribution of the current belongs to this article only in so far as electric traction has introduced peculiarities in the type of apparatus or the methods of its use. In a continuous current station the current is generated at an approximately constant potential, varying from 500 volts to 700 volts on different systems. As the load is apt to fluctuate, except in large stations, within wide limits, the machinery must be designed to stand the most severe usage. The engines are more massive than would be necessary for constant loads, and the dynamos must be built to stand sudden overloads without destructive sparking; usually, indeed, they are considerably over-compounded, not so much for the sake of raising the voltage as to strengthen the field and prevent sparking on overload. When a number of machines are to be run in parallel—as is usually the case—they are provided with "equalizing" switches, which serve to throw the series fields in parallel. As a result, if one of the machines tends to increase its armature current beyond the proper amount, the current in the series fields does not increase with it, but retains its normal proportion. The armature reaction and resistance fall of potential, in this machine, would both tend to increase, thereby decreasing its armature potential, and therefore its current would return to its proper value. From the dynamos the current from each machine goes through an ammeter and automatic circuit-breaker to the main "omnibus" bars, then through the station ammeter to the feeder "omnibus" bars, then through ammeters and circuit-breakers to the feed-cables. As a rule, watt-meters are provided to measure the output of the station, and, if an overhead system is being supplied, lightning arresters are installed. Where continuous currents are used to operate cars at considerable distances from the generating stations, "boosters" are used. These are series-wound dynamos driven at a constant speed, through which is passed the current that is to feed the distant section of the line. Usually the characteristic of the booster is so calculated that the amount by which it raises the voltage for a given current just equals the fall of potential in the feeding-line for the same current. The result is that the potential at the end of the line will be the same as that at the station. The question of economy, as between putting in additional copper and wasting energy in the booster, is easily calculated; the advantage is more and more on the side of the latter as the distance increases and the car service becomes more infrequent. It is necessary to the satisfactory operation of a system that the variations of voltage should not be too great, so boosters sometimes become a practical necessity, irrespective of the question of economy.

Generation of Current.

Accumulators are frequently installed in power stations to prevent the heavy load fluctuations which arise from starting and stopping of cars and ascending or descending grades. The generators give an approximately unvarying amount of current. When the load demand is less than that delivered by the generators, the excess current goes into the storage battery, and when the load is greater than the power from the generators the additional current required comes from the battery. The generators, engines and boilers may thus be proportioned for the average instead of the maximum load requirements, and the sizes of these units are thereby reduced.

As traction systems have been combined and extended, the area of operation of many of the companies has grown so that a number of direct-current stations are used for a single system. The limit of distance to which electric energy can be economically supplied at the comparatively low voltages employed is not great, and the advantage of having one or two large stations to supply a system, in place of a number of smaller ones, is evident. This fact has led to the use of high-potential alternating currents for the distribution of energy, the voltage being reduced at the points of consumption, and in most cases changed to a continuous current by rotary converters. If alternating currents are used for the car motors, the economical distribution of energy is greatly simplified, the rotary converters being eliminated and their first cost and losses and expense of operation saved. The expense of operating sub-stations containing rotary converters is necessarily large, and the capital outlay required for them is often greater than for the generating station.

As a rule, the cars used for electric traction have varied but slightly from the type of tramway car prevalent in different localities. The tendency, however, has been to increase their size. For electric railway work, as distinguished from tramway work, the cars generally follow the pattern that is standard on American steam lines. The trucks used for electric cars are made of steel, with heavy axles and suspension bars for carrying the electric motors. For smaller vehicles, a single four-wheel truck is used, the wheel base being limited by the curvature of the track, but not as a rule exceeding $7\frac{1}{2}$ ft. For the longer and heavier cars, two four-wheeled bogie trucks are employed. If two motors are used on a double-truck car, and if the grades on the road are very heavy, the trucks are made on the "maximum traction" pattern, in which one pair of wheels in each truck is of smaller diameter than the other and the greater part of the weight of the car is on the larger motor-driven wheels. For very large high-speed cars, trucks are used of practically the same type and weight as are employed on steam railways. (See also TRAMWAY.) (L. DU.)

Cars.

TRACY, ANTOINE LOUIS CLAUDE DESTUTT, COMTE DE (1754–1836), French philosopher, son of a distinguished soldier, was born in Bourbonnais on the 20th of July 1754. He belonged to a noble family of Scotch descent, tracing its origin to Walter Stutt, who in 1420 accompanied the earls of Buchan and Douglas to the court of France, and whose family afterwards rose to be counts of Tracy. He was educated at home and at the university of Strassburg, where he was chiefly noted for his athletic skill. He went into the army, and when the Revolution broke took an active part in the provincial assembly of Bourbonnais. He was elected a deputy of the nobility to the states-general, where he sat alongside of his friend La Fayette. In the spring of 1792 he received the rank of *maréchal de camp* in command of the cavalry in the army of the north; but the influence of the extremists becoming predominant he took indefinite leave of absence, and settled at Auteuil, where, with Condorcet and Cabanis, he devoted himself to scientific studies. Under the Reign of Terror he was arrested and imprisoned for nearly a year, during which he studied Condillac and Locke, and abandoned the natural sciences for philosophy. On the motion of Cabanis he was named associate of the Institute in the class of the moral and political sciences. He soon began to attract attention by the *mémoires* which he read before his colleagues—papers which formed the first draft of his comprehensive work on ideology. The society of "ideologists" at Auteuil embraced, besides Cabanis and Tracy, Constantin François de Chassebœuf, Comte de Volney and Dominique Joseph Garat (1749–1833), professor in the National Institute. Under the empire he was a member of the senate, but took little part in its deliberations. Under the Restoration he became a peer of France, but protested against the reactionary spirit of the government, and remained in opposition. In 1808 he was elected a member of the French Academy in place of Cabanis, and in 1832 he was also named a member of the Academy of Moral Sciences on its reorganization. He appeared, however, only once at its conferences, owing to his age and to disappointment at the comparative failure of his work. He died at Paris on the 9th of March 1836.

Destutt de Tracy was the last eminent representative of the sensualistic school which Condillac (*q.v.*) founded in France upon a one-sided interpretation of Locke. He pushed the sensualistic principles of Condillac to their last consequences, being in full agreement with the materialistic views of Cabanis, though the attention of the latter was devoted more to the physiological, that of Tracy to the psychological or "ideological" side of man. His ideology, he frankly stated, formed "a part of zoology," or, as we should say, of biology. To think is to feel. The four faculties into which he divides the conscious life—perception, memory, judgment, will—are all varieties of sensation. Perception is sensation caused by a present affection of the external extremities of the nerves; memory is sensation caused, in the absence of present excitation, by dispositions of the nerves which are the result of past experiences; judgment is the perception of relations between sensations, and is itself a species of sensation, because if we are aware of the sensations we must be aware also of the relations between them; will he identifies with the feeling of desire, and therefore includes it as a variety of sensation. It is easy to see that such conclusions ignore important distinctions, and are, indeed, to a large extent an abuse of language. As a psychologist de Tracy deserves credit for his distinction between active and passive touch, which developed into the theory of the muscular sense. His account of the notion of external existence, as derived, not from pure sensation, but from the experience of action on the one hand and resistance on the other, may be compared with the account of Bain and later psychologists.

His chief works are *Eléments d'idéologie* (1817–1818; 2nd ed., 1824–1825), in which he presented the complete statement of his earlier monographs; *Commentaire sur l'esprit des lois de Montesquieu* (1806; 5th ed., 1828; Eng. trans., President Jefferson, 1811); *Essai sur le génie et les ouvrages de Montesquieu* (1808). See histories of philosophy, especially F. Picavet, *Les Idéologues* chs. v. and vi. (Paris, 1891), and *La Philosophie de Biran* (Académie des sci. mor. et pol., 1889); G. H. Lewes, *Hist. of Phil.*

TRACY, BENJAMIN FRANKLIN (1830–), American lawyer and soldier, was born in Owego, New York, on the 26th of April 1830. He was educated at the Owego academy, was admitted to the bar in 1851, was district-attorney of Tioga county in 1853–1859, and was a member of the state Assembly in 1862. In 1862 he organized the 109th and the 137th regiments of New York Volunteer Infantry and (Aug. 28) was made colonel of the former. In September 1864 he became colonel of the 127th United States Colored Infantry; in 1864–1865 was in command of the prison camp at Elmira, New York, and in March 1865 was breveted brigadier-general of volunteers. He received a Congressional medal of honour in 1895 for gallantry at the Wilderness in May 1864. He was United States district-attorney for the eastern district of New York in 1866–1873, and an associate judge of the New York court of appeals in 1881–1882. In 1889–1893 he was secretary of the navy in the cabinet of President Benjamin Harrison, and then resumed the practice of law in New York City. He was chairman of the commission which drafted the charter for Greater New York, and in 1897 was defeated as Republican candidate for mayor of the city. In 1899 he was counsel for Venezuela before the Anglo-Venezuelan boundary arbitration commission in Paris.

TRADE (O. Eng. *trod*, footstep, from *tredan*, to tread; in M. Eng. the forms *tred*, *trod* and *trade* appear, the last in the sense of a beaten track), originally a term meaning track or course, and so surviving in "trade-wind" (*q.v.*), a wind which always blows in one course; hence a way of life, business or occupation, and, specifically, the handicraft in which a man has been trained and which he makes his means of livelihood, or the mercantile business which he carries on for profit, as opposed to the liberal arts or professions. A further development of meaning makes the word synonymous with commerce, comprehending every species of exchange or dealing in commodities.

See COMMERCE; BALANCE OF TRADE; FREE TRADE; PROTECTION; TARIFFS; TRADE ORGANIZATION; and also the sections dealing with trade and commerce under the various countries.

TRADE, BOARD OF. The greater part of such supervision of commerce and industry as exists in the United Kingdom is exercised by the "Committee of Privy Council for Trade" or, as it is usually called, the board of trade. As early as the 14th century councils and commissions had been formed from time to time to advise parliament in matters of trade, but it was not till the middle of the 17th century, under the Commonwealth, that any department of a permanent character was attempted. Cromwell's policy in this respect was continued under the Restoration, and in 1660 a committee of the privy council was appointed for the purpose of obtaining information as to the imports and exports of the country and improving trade. A few years later another committee of the council was appointed to act as intermediaries between the crown and the colonies, or foreign plantations, as they were then called. This joint commission of trade and plantations was abolished in 1675, and it was not until twenty years later that it was revived under William III. Among the chief objects set before this board were the inquiry into trade obstacles and the employment of the poor; the state of the silver currency was also a subject on which John Locke, its secretary, lost no time in making representations to the government. Locke's retirement in 1700 removed any chance of the board of trade advocating more enlightened opinions on commercial subjects than those generally held. It had only a small share in making the constitutions of the American colonies, as only the Carolinas, Pennsylvania, Georgia and Nova Scotia were formed after the reign of Charles II.; and in 1760 a secretary of state for the colonies was appointed, to whom the control drifted away. In 1780 Burke made his celebrated attack on the public offices, which resulted in the abolition of the board. In 1786, however, another permanent committee of the privy council was formed by order in council, and with one or two small exceptions the legal constitution of the board of trade is still regulated by that order. Under it all the principal officers of state, including the first lords of the treasury and admiralty, the secretaries of state, and certain members of the privy council, among whom was the archbishop of Canterbury, obtained seats at the board *ex officio*; and ten unofficial members, including several eminent statesmen, were also placed on the committee. The duties of the revived board were made the same as they were in the beginning of the century, but the growth of commerce necessarily threw new administrative duties upon it. The board of trade thus became a mere name, the president being practically the secretary of state for trade, and the vice-president became, in 1867, a parliamentary secretary, with similar duties to those of a parliamentary under-secretary of state. At present, besides the president, who has usually a seat in the cabinet,[1] and whose salary is £5000 a year, there is a parliamentary secretary with a salary of £1200, a permanent secretary (salary £1500, rising to £1800), and four assistant secretaries (each with a salary of £1200) for the harbour, marine, commercial, labour and statistical, and railway departments. There are also other important officials in charge of different departments, as mentioned below.

1. *The Commercial, Labour and Statistical Department* is the real remains of the original board of trade, as it combines the charge of the trade statistics with the general consultative duties with which King Charles II.'s board was originally entrusted. The statistical work includes compiling abstracts, memoranda, tables and charts relating to the trade and industrial conditions of the United Kingdom, the colonies and foreign countries, the supervision of the trade accounts, the preparation of monthly and annual accounts of shipping and navigation, statistics as to labour, cotton, emigration and foreign and colonial customs, tariffs and regulations. The commercial intelligence department collects and disseminates accurate information on general commercial questions, and collects and exhibits samples of goods of foreign origin competing with similar British goods. It keeps a register of British firms who may desire to receive confidential information relative to their respective trades and supplies that information free of charge. The labour statistics published by the department are exhaustive, dealing with hours of labour, the state of the labour market, the condition of the working classes and the prices of commodities; annual reports are also

[1] Since 1882 there have been only two occasions on which the president of the board was not included in the cabinet. Frequent suggestions were made as to raising the status and salary of the president of the board, which up to 1900 was £2000. Lord Jersey's committee in 1904 suggested that the president should be put on the same footing as a secretary of state, and be given the title of "minister of commerce and industry." In 1909 the Board of Trade Act repealed the Board of Trade (President) Act 1826, which limited the salary of the president, and enacted that the president should be paid such annual salary as parliament might determine (£5000). The increased salary came into operation in 1910, when a new president of the board came into office.

published of trade unions, of strikes and lock-outs and other important subjects. The staff comprises a controller-general (salary £1200 rising to £1500), a deputy controller-general and labour commissioner, a principal for statistics, a principal of the commercial department, an assistant labour commissioner, a chief staff officer for commercial intelligence, a chief labour correspondent, a special inquiry officer, and a staff of investigators and labour correspondents. The department also edits the *Board of Trade Journal* (started in 1886), giving items of commercial information, trade and tariff notices and various periodical returns. There are also branches which deal with the census of production, labour exchanges, &c.

2. *The Railway Department* was originally constituted in 1840, and performs multifarious duties under various railway acts, including the inspection of railways before they are open, inquiries into accidents, reports on proposed railways, approval of by-laws, appointment of arbitrators in disputes, as well as many duties under private railway acts. The inspection of tramways, their by-laws and "provisional orders" are all dealt with here, as are similar orders relating to gas and water schemes and to electric lighting. There is a special office of inspection of railways with a chief inspecting officer (salary £1400) and an assistant staff. Patents, designs and trade marks are now dealt with by the patent office under the charge of a controller-general (salary £1800), which is subordinate to the railway department, and copyright, art unions and industrial exhibitions are also among the matters dealt with by the department. Annual returns with regard to its business are published by the department.

3. *The Marine Department* was created a separate branch of the board of trade in 1850, about which time many new and important marine questions came under the board of trade, such, for example, as the survey of passenger steamers, the compulsory examination of masters and mates, the establishment of shipping offices for the engagement and discharge of seamen. Further work fell to the marine department by the act of 1853, which gave it the control of lighthouse funds, and to a certain extent of pilotage. The consolidating Merchant Shipping Act of 1854 and subsequent legislaticn so much increased the department that in 1866 it was divided into three, viz. the present marine department, which deals with ships and seamen, the harbour department and the finance department.

4. *The Harbour Department* was, as stated above, a branch of the marine department until 1866, so far as it is connected with the physical adjuncts of navigation, but various other matters have since been added, *e.g.* the charge of the foreshores belonging to the crown, formerly managed by the commissioners of woods and forests, and the protection of navigable harbours and channels, long under the control of the admiralty, provisional orders under the General Pier and Harbour Acts and under the Pilotage Acts, and the settlement of by-laws made by harbour authorities. Control over the lighthouse funds of the lighthouse authorities of the United Kingdom, the registry of British ships, wreck, salvage and quarantine are all among the matters dealt with by this department, which also has charge of the standards department for weights and measures.

5. *The Finance Department* was, like the harbour department, separated in 1866 from the marine department. The accounts of all the branches of the board of trade are in its charge, including the subordinate offices. It also deals with the accounts of harbours, lighthouses and mercantile marine offices, and of the merchant seamen's fund, and with the consuls' accounts for disabled seamen abroad. Savings banks and seamen's money orders are also among the accounts and payments with which it is charged, and outside these marine matters it has to prepare for parliament the life insurance companies' accounts and to take charge of the bankruptcy estate accounts.

6. *The Bankruptcy Department* was established under the 71st section of the Bankruptcy Act 1883. At its head is the inspector-general in bankruptcy (salary £1200). An account of the duties of the department will be found under BANKRUPTCY.

7. *The Fisheries Department.*—By an act of 1886 the powers of the home office over salmon and other fisheries were transferred to the board of trade, and a small department was consequently created charged with the care of those industries. But by an act of 1903 (3 Ed. VII. c. 31) the powers and duties of the board of trade under this department were transferred to the board of agriculture and fisheries.

TRADE MARKS. A "trade mark" may be defined as a symbol, consisting in general of a picture, a label or a word or words, applied or attached to the goods of a trader for the purpose of distinguishing them from the similar goods of other traders, and of identifying them as his goods, or as those of his successors, in the business in which they are produced or put forward for sale. A trade mark differs in its legal character both from a patent and from a copyright. In the case of a trade mark the property and the right to protection are in the device or symbol adopted to designate the goods to be sold, and not in the article which is manufactured and sold. The article is open to the whole world to manufacture and sell, and all that the owner of the trade mark is entitled to prevent is such use of his mark by other traders as will lead purchasers to buy, as his, goods which are not his. On the other hand, patent-right and copyright protect the substance of the article; and any unauthorized manufacture of it in the former case, or reproduction of it in the latter, while the protection lasts, is prohibited. The grounds, however, on which trade marks, patent-right and copyright obtain legal recognition, though they are to a certain extent dissimilar, have a common element. Patent-right and copyright rest upon the view that the results of the original labour of the inventor and the author ought, as a matter alike of justice and of public policy, to be secured against piracy; while, as regards the proprietor of a trade mark, the question of originality does not arise so long as the mark is sufficiently distinctive really to identify his goods and, for purposes of registration, to satisfy the Trade Marks Acts. In truth, the registration of a trade mark is rather the recognition of a fact than the grant of a privilege (Kerly and Underhay, *Trade Marks Act*, 1905, p. 3). The law as to trade marks as well as that as to patents or copyright is based on a man's rights to have guaranteed to him the profit derivable from his own property. "No man," said James (L.J.), in the case of the *Singer Manufacturing Co.* v. *Loog* (1880, 18 Ch. D., 412), "is entitled to present his goods as being the goods of another man, and no man is permitted to use any mark, sign or symbol, device or means, whereby, without making a direct false representation himself to a purchaser from him, he enables such purchaser to tell a lie or to make a false representation to somebody else who is the ultimate customer."

I. *British Trade Marks before the Registration Acts.*—The existing law in the United Kingdom cannot be properly appreciated unless the subject is approached in the first instance from the historical side. English trade-mark law practically commences with the first years of the 19th century. The use of trade marks was indeed of far earlier date, for in 1742 we find Lord Hardwicke declaring that "every particular trader had some particular mark or stamp." But in the very case in which Lord Hardwicke made that statement (*Blanchard* v. *Hill*, 2 Atkyns, 484) he refused to protect the "Great Mogul" stamp on cards, being apparently under the influence of the notion that the legal recognition of trade marks would involve the creation of a new species of monopoly; and with regard to a case decided in the reign of James I. (*Southern* v. *How*, Cro. Jac. 471), in which a clothier had applied the mark of another clothier to his own inferior goods, the reports leave it doubtful whether the action was brought by the owner of the mark, or by a defrauded customer, in which latter event it would be merely an ordinary action for deceit. But although the actual law of trade marks cannot be traced farther back than the beginning of the 19th century, Lord Eldon repeatedly granted injunctions to restrain one trader from fraudulently "passing off" his goods as those of another, and thus laid a foundation on which the present law has been built up. The stages through which its development passed possess considerable interest, and may be described quite briefly. The first reported case—apart from the doubtful one in the time of James I. above referred to—in which the infringement of a trade mark (a label on blacking) was restrained by the court of chancery was *Day* v. *Day* (Eden on *Injunctions*, ed. 1821, p. 314) in 1816. In 1824 the common law courts, in the case of *Sykes* v. *Sykes* (3 B. & C. 541), established the right of the owner of an infringed trade mark to damages. In 1833 it was held by the court of king's bench that it was not necessary for the plaintiff in an infringement action to prove that the defendant's goods were inferior to his, or that he had suffered special damage by the infringement. Later this became a rule of equity as well as of law. On another point, however, the practice of the courts of common law and equity diverged for a time. It was decided by Lord Cottenham in 1838, in the leading case of *Millington* v. *Fox* (3 Mylne & Craig 338), that an injunction to restrain the infringement of a trade mark could be obtained, even although the defendant had acted without fraudulent intent. On the common law side, on the other hand, fraud was an essential ingredient in the cause of action, and remained so till the fusion of law and equity by the Judicature Acts.

The effect of Lord Cottenham's decision in the case of *Millington* v. *Fox* clearly was to recognize a right of property in trade marks, and the action for infringement became a familiar species of litigation. Under the then existing law, however, the plaintiff in such actions generally found himself in a very disadvantageous and unsatisfactory position. The basis of his action was the reputed association between his trade mark and his goods. This association the defendant—often a person of no means—would deny, and it had to be proved as a fact by witnesses at a cost to the plaintiff which there was little hope of his recovering. Moreover, even if the trade mark proprietor secured a judgment in his favour, it carried with it no immunity from the obligation of again establishing his right to the mark against any subsequent infringer who chose to dispute it. Thus—to take an interesting and pertinent illustration given in *Kerly on Trade Marks* (p. 6)—the case of *Rodgers* v. *Nowill* (22 L. J. Ch. 404) lasted five years and cost the plaintiff £2211, without giving him in the end any security that he might not have to incur equal delay and expense in proving his title to the exclusive use of the trade mark in proceeding against other defendants. To complete this statement of the shortcomings of the law before the Merchandise Marks Act 1862, it should be noted that the infringement of trade marks—except in cases where the seller of spuriously marked goods cheated the buyer—was not a criminal offence. The remedies obviously needed were the establishment of a system of registration of trade marks which would simplify the proof of a plaintiff's title, and the creation of a criminal law of false marking.[1] The first step in the accomplishment of the latter object was taken by the Merchandise Marks Act 1862.

II. *Under the Registration Acts.*—Provision was first made for the registration of trade marks by the Trade Marks Registration Act 1875. That statute made registration in the register of trade marks which it established prima facie evidence of the right of the registered proprietor to the exclusive use of the trade mark in connexion with goods of the class for which it was registered and used, and enacted that it should after the expiration of five years be conclusive proof of such right, provided that the proprietor of the mark remained the owner of the goodwill of the business in which it was used. This provision was carried as to the act of 1883 (s. 76). The act also provided that a person should not be entitled to institute any proceeding to prevent the infringement of trade mark until it was registered, or (a later statutory modification) until, in the case of a mark in use before the passing of the act of 1875, registration of the mark as a trade mark had been refused. The act of 1875 was a considerable success, but no provision was made under it for the registration of words unless they either were old marks or were registered in combination with one or more of the "essential particulars" prescribed by the act, such as a distinctive device, heading, mark, label or ticket. These limitations excluded from registration most of the trade marks ordinarily in use.

The Patents Designs and Trade Marks Act 1883 remedied this defect besides altering the law in other important respects. The act of 1883 was amended in 1888 on the recommendation of a committee presided over by Lord Herschell. Neither the act of 1875 nor those of 1883 and 1888 altered the common law definition of a trade mark, nor contained any definition of the term. The description in the acts of what was registrable as a trade mark led to much litigation, and the interpretations of the judges left commercial men dissatisfied on three points: (1) the number of good and valuable trade marks which were not registrable; (2) that on allowing registration the patent office insisted on disclaimers which hampered the owner in obtaining protection in the colonies and foreign countries; (3) that there was no effective period of limitation to attacks on registered trade marks, because though registration for five years was declared conclusive by s. 76 of the act of 1883, the powers of the court to rectify the register could be invoked even after the lapse of the five years (*re Gestetner's Trade Mark*, 1907, 2 Ch. 478). In re-enacting and enlarging the provisions of the act of 1875 the act of 1883 laid down certain essential particulars of one at least whereof a trade mark must consist to be registrable. These particulars will be considered later in dealing with the present law. The act of 1883 first provided for "word marks," and included among them "a fancy word or words not in common use" [s. 64, (1) (c)].

The expression "fancy word," used in the act of 1883, gave rise to considerable difference of opinion. It was interpreted by the court of appeal as equivalent to "obviously meaningless as applied to the article in question," or "obviously non-descriptive." In accordance with this interpretation, the words "gem" for guns, "melrose" for a hair restorer, "electric" for velveteen, and "washerine" for a soap were all held not to be registrable. On the recommendation, however, in 1887, of a committee appointed by the board of trade, and presided over by Lord Herschell, the expression "invented word" was substituted for "fancy word" by the act of 1888.

In 1905 and 1907 the legislation as to trade marks was amended and remodelled. A bill was introduced in 1905 at the instance of the London Chamber of Commerce, and after consideration by a select committee became the Trade Marks Act 1905. This act repeals the bulk of the provisions of the Patents, &c., Acts of 1883 and 1888 with respect to trade marks, and embodies them with amendments (to be noticed later) in a separate statute. The only portions of the earlier acts left standing with respect to trade marks were ss. 83 and 84 (as amended in 1885 and 1888) with reference to the administration in the patent office of the law as to trade marks (1905, s. 74); ss. 103 and 104 of the act of 1883 (as amended in 1885) relating to registration of trade marks, both as enacted in the acts of 1883 and 1885 and as applied by orders in council, are to be read as applying to trade marks registrable under the act of 1905 (s. 65). The sections of the Patents Acts of 1883, 1885 and 1888, thus preserved as to trade marks, were repealed by the Patents and Designs Act 1907. Sections 62 seq. of this act replace ss. 83 and 84 of the act of 1883, and retain the administration of trade mark law in the patent office; and s. 91 replaces ss. 103 and 104 of the act of 1883 as to international and colonial arrangements for mutual protection (*inter alia*) of trade marks. According to the rule laid down by the Interpretation Act 1889 the references in the act of 1905 to the acts of 1883, &c., are to be read as applying to the above-stated sections of the act of 1907.

The act of 1905 differs from the preceding acts in containing a definition of trade mark for the purposes of the act unless the context otherwise requires; viz. that it "shall mean a mark used or proposed to be used upon *or in connexion* with goods for the purpose of indicating that they are the goods of the proprietor of such mark by virtue of manufacture, selection, certification, dealing with or offering for sale"; and "mark" is defined as *including* "a device, brand, heading, label, name, signature, word, letter, numeral or any combination thereof" (s. 3). The act, modifying to the extent indicated in italics the acts of 1883 and 1888, prescribes (s. 9) that a trade mark to be registrable must contain or consist of at least one of the following essential particulars:—

1. The name of a *company*, individual or firm represented in a *special* or particular manner (under the act of 1883 it has been held that the name must be in the nominative case, and that ordinary printing is not representation in a particular manner).

2. The signature of the applicant for registration or some predecessor in his business. It is not clear that this includes descriptive trading styles.

3. An invented word or words.

4. A word or words having no *direct* reference to the character or quality of the goods, and not being *according to its ordinary signification* a geographical name *or a surname.*

5. *Any other distinctive mark; but a name, signature, or word or words other than such as fall within the descriptions in the above paragraphs 1, 2, 3 and 4, shall not, except by order of the board of trade or of the court, be deemed a distinctive mark.* By distinctive is meant "adapted to distinguish the goods of the proprietor of the trade mark from those of other persons": and "in determining whether a trade mark is so adapted the tribunal may in the case of a trade mark in actual use take into consideration the extent to which such

[1] Further reference may be made, in regard to the subject of trade marks before the Registration Acts 1883–1888, to an admirable introductory chapter in *Kerly on Trade Marks*, and also to the report of the Merchandise Marks Committee 1862, and the annual reports of the commissioners and the comptroller-general of patents from 1876 to 1884 (2nd report).

user has rendered such trade mark in fact distinctive for the goods in respect of which it is registered or proposed to be registered." Where the mark is limited to specified colours, that fact may be taken into account in deciding whether the mark is distinctive (s. 10). There are certain special rules as to cotton marks.

Trade marks containing the essential particulars are not registrable if they contain any matter which would by reason of its being calculated to deceive or otherwise be disentitled to protection in a court of justice or would be contrary to law or morality, or any scandalous design (s. 11). (See *Eno* v. *Dunn*, 1890, 15 App. Cas. 293, and the "Motricine" case, 1907, 2 Ch. 435.) Registration of the same matter as a trade mark under the act of 1905 and as a design under the Patents and Designs Act (1907) is possible (*re U.S. Playing Card Co.'s Applic.*, 1907, W. N. 251).

Old marks are registrable, *i.e.* any special or distinctive word or words, letter, numeral or combination of letters or numerals, used by the applicant or his predecessors in business before the 14th of August 1875, subject to the qualification that it has "continued to be used either in its original form or with additions or alterations not substantially affecting the same down to the date of the application for registration" (s. 9). In the case of new marks, but not of old marks, a trade mark is not registrable except by order of the court in respect of any goods or description of goods which is identical with a mark already on the register with respect to such goods or description of goods, or so nearly resembles such registered mark as to be calculated to deceive (s. 19).

Most controversy arose under the acts of 1883 and 1888 as to the meaning of the phrase "invented word" preserved in the act of 1905. An invented word need not be wholly meaningless, nor is it disqualified because words may have suggested it. Thus "mazawattee" was held to be an "invented word," although the latter part of it was a Sinhalese term meaning "estate," and there were estates in Ceylon having names ending with "wattee" from which tea came; and in a leading case on the construction of the clauses under consideration (*Eastman Co.'s Trade Mark*, L. Rep. 1898, A. C. 571), the word "solio" was held to be registrable as a trade mark for photographic printing paper under both clauses, although it was objected that "solio" was equivalent to "sunio." The expression "calculated to deceive" has been considered by the courts in very many cases. It is not merely or chiefly the retailer or dealer who has to be kept in view when the question of the likelihood of deception is under consideration. The courts have regard also, and mainly, to the ultimate purchaser whom the trade mark may reach, and careless or unwary persons are considered as well as those who are careful and intelligent. The judge's eye is the ultimate test as to the degree of resemblance that is calculated to deceive, although expert evidence on the point is admissible. "Savonol" for soap (*J. C. & J. Field Ltd.* v. *Wagel Syndicate Ltd.*, 1900, 17 R.P.C. 266), "tachytype" for typographical and composing machines (in *re Linotype Co.'s Application*, 1900, 17 R.P.C. 380), have been held to be invented words. But the following have been held not invented—"uneeda" (=you need a) in *re National Biscuit Co.* (1902; 1 Ch. 783); "absorbine" for an absorbent preparation (*Christy & Co.* v. *Tipper & Son*, 1905, 21 R.P.C. 97, 775); "bioscope" (*Warwick Trading Co.* v. *Urban*, 1904, 21 R.P.C. 240); "cyclostyle" (*re Gestetner's Trade Mark*, 1907, 2 Ch. 478); and cf. in *re Kodak and Trade Marks* (1903, 20 R.P.C. 337).

Invented Words.

Subsections (3) and (4), it should be noted, are independent: the former deals with newly-coined words, the latter deals with the existing words of the English language, or of other languages likely to be known to the public. A word which is really "invented" may be registered, whether it is descriptive or not. An old word used in a new sense is not invented (*Hommel* v. *Bauer & Co.*, 1904, 21 R.P.C. 576). The exact scope of clause (5) as to other distinctive marks has not been much discussed by the courts. Registration was allowed of the word "apollinaris" as a distinctive mark for the mineral waters of the applicants, on an undertaking to apply it only to water from the Neuenahr spring or district (in *re Apollinaris Trade Mark*, 1907, 2 Ch. 178). Under prior legislation the mark had been refused registration as being a geographical name (*re Apollinaris Co.'s Trade Mark*, 1891, 2 Ch. 186).

Identical marks (except old marks) may not be registered in respect of the same goods, or goods of the same description, for two different persons (s. 19); and where several applicants make rival claims to identical marks the registrar may refuse to register until their rights have been determined by the court or settled by agreement in manner approved by the registrar, or, on appeal, by the board of trade (s. 20). In the case of honest concurrent user or of other special circumstances making it proper so to do, the court may permit the registration of the same mark or of nearly identical marks for the same goods by more than one owner, subject to such conditions or limitations, if any, as to mode or place of use or otherwise as the court may think it right to impose (s. 21).

Identical Marks.

New provisions were made in 1905 as to what are called "associated trade marks." Where registration is sought for a mark so closely resembling a mark of the applicant already on the register for the same goods as to be calculated to deceive or cause confusion if used by any one but the applicant, the registration of the new mark may be conditional on entering both marks as associated trade marks (s. 24). This section applies only to marks closely resembling one already on the register for the same goods or description of goods, and has nothing to do with identical marks (*Birmingham Small Arms Co.'s Application*, 1907, 2 Ch. 396).

Associated Marks.

In the case of combined trade marks provision is made for registering as separate trade marks the part in which the applicant has exclusive rights, and as associated marks trade marks of which the exclusive portion forms a part (s. 25).

A series of trade marks of the same owner may be registered on one registration as associated marks (s. 26).

Provision is made for allowing the registration of marks used upon or in connexion with goods by an association (or person) which undertakes the examination of goods in respect of origin, material, mode of manufacture, quality, accuracy, or other characteristic, and certifies the result of the examination by marks used upon or in connexion with the goods. These marks cannot be registered unless the board of trade consider their registration of public advantage. Their registration is not conditional on the association or person being a trader or having goodwill in connexion with the examination or certification. The registration gives the association or person the rights of the owner of a registered trade mark, except that assignment and transmission needs permission of the board of trade (s. 62).

Standardization Marks.

In respect of cotton piece-goods, marks consisting of a line heading alone or a word alone are not registrable, and no word or line heading is treated as distinctive in respect of such goods. In respect of cotton yarn the same rule applies with respect to words, and no registration of any cotton mark gives any exclusive right to the use of a word, letter, numeral, line, heading or combination thereof [s. 64 (10)].

Cotton Marks.

By s. 68, which is a re-enactment of s. 105 of the Patents, &c., Act, 1883, it is made illegal for any person without the authority of the king to use the royal arms in any trade in such a manner as to create the belief that he has authority so to do; a similar provision is embodied in the Merchandise Marks Act 1898 of the Isle of Man.

Use of Royal Arms, &c.

The central register of trade marks is kept at the Patent Office, Southampton Buildings, London, and is under the charge of the comptroller-general of patents, designs and trade marks, who is appointed by and acts under the superintendence of the board of trade, and has a deputy—the registrar of trade marks. There is a branch registry at Manchester, whose chief officer is the keeper of cotton marks, which deals with all applications for the registration of trade marks for cotton goods falling within classes 23, 24, 25 in schedule 3 of the Trade Marks Rules 1906. The registry has been long established, but was not recognized by statute till 1905. Records are kept and are open to public inspection of all applications made since 1875, whether granted or refused.

Registries.

There is a branch registry at Sheffield containing the marks for metal goods ("Sheffield marks") registered by persons carrying on business in or within six miles of Hallamshire. The care of this register is vested in the Cutlers' Company, who are substituted for the comptroller as to registration of "Sheffield marks" (s. 63). Applications made to the company are notified to the registrar, and may not be proceeded with if he objects. Any person aggrieved by the registrar's objection may appeal to the court. Applications made to the registrar for metal marks are notified to the Cutlers' Company. Persons aggrieved by the decision of the Cutlers' Company have an appeal to the courts (s. 64).

In 1906 fourteen applications were made at the head registry which were all dealt with by the Cutlers' Company. That company, by arrangement made with the sanction of the treasury, retain all fees taken at Sheffield with respect to registration up to £400, and half of the fees received in excess of that amount (*Parl. Pap.*, 1907, No. 164, p. 9).

A trade mark must be registered in respect of particular goods or classes of goods (s. 8), and the classification in force is scheduled to the Trade Marks Rules 1906 (R. & O., 1906, No. 233). Doubts as to the class to which the goods in question belong are settled by the registrar. The procedure for obtaining registration is regulated by the act of 1905 and the rules above mentioned. The registrar has power to refuse applications or accept them absolutely or subject to conditions, amendments and modifications (s. 12). His discretion is not absolute, but subject to the provisions of the act (*re Birmingham Small Arms Co.'s Application*, 1907, 2 Ch. 396); and he must if required state his reasons, and his decision is subject to appeal to the board of trade or the court at the option of the applicant [s. 12 (3)].

Procedure.

"New marks" may not be placed on the register except by order of the court for any goods or description of goods which are identical with marks already on the register with respect to the same goods, &c., or so nearly resemble a registered mark as to be calculated to deceive (s. 19). The question whether particular goods are of the same description is not determined solely by reference to the statutory classification. "The true test," says Kerly (*Trade Marks*, p. 181), "would seem to be supplied by the question: Are the two sets of goods so commonly dealt in by the same trader that his customers, knowing his mark in connexion with one set, and seeing it upon the others, would be likely to suppose that it was used upon them also to indicate that they were his goods?" Wine and spirits, beer, and even aperient drinks and baking powder, have been held to be "goods of the same description." When a trade mark contains (1) parts not separately registered as trade marks or (2) matter common to the trade or otherwise of a non-distinctive character, the registrar, or the board of trade or the court, in deciding whether the mark shall be entered or retained on the register, may impose as a condition that the owner shall disclaim all right to exclusive use of any part or parts of such trade mark or of all or any portion of such matter to the exclusive use whereof they deem him not to be entitled, or make any other disclaimer which they consider needful to define his rights under the registration (s. 15). Marks calculated to deceive are not entitled to protection (*Eno* v. *Dunn*, 1890, 15 App. Cas. 250).

Applications as accepted are advertised; the advertisements state the conditions, if any, imposed on acceptance (s. 13). Notice of opposition to the registration of a trade mark may be given under s. 14 of the act of 1905 (which replaces s. 69 of the act of 1883). The registrar after consideration decides whether the opposition is well or ill founded. His decision is subject to appeal to the High Court or by consent of the parties to the board of trade [1905, s. 14 (5)]. In 1906 there were 251 notices of opposition, of which 51 were heard. There were 4 appeals to the board of trade, all referred by the board to the court under s. 59 of the act.

There may be added to any one or more of the "essential particulars" above enumerated any letters, words or figures, or a combination of these. But the right to the exclusive use of the added matter must be disclaimed. A man is not required, however, to disclaim his own name, or trade name, or that of his place of business, if the name appears in the mark. The number of applications to register trade marks in 1884 was 7104, and the number of marks registered 4523. In 1906 the corresponding figures were 11,414 and 4731. These figures included 153 applications made to the Cutlers' Company at Sheffield (*Parl. Pap.*, 1907, 164, 24th report).

Correction and Alteration of the Register.

The register may be corrected on the request of the registered owner of a trade mark as to errors or changes of address in the name of the registered owner, or by cancelling entries of marks or by striking out classes of goods for which a mark is registered or by entering disclaimers or memoranda as to a mark, provided that they do not extend the rights given by the existing registration (s. 33).

A registered trade mark may be altered or added to in matters not substantially affecting its identity (s. 34). Thus a firm on becoming a limited company has been allowed to add the word "limited" to its name upon a registered mark, but no alteration will be permitted in regard to any "essential particular." In the above cases the corrections or alterations are made by the registrar subject to appeal to the board of trade (ss. 32, 34). A registered trade mark may be taken off by order of the court on the application of a person aggrieved, on the ground that it was registered without a bona fide intention to use it in connexion with a particular class of goods, and that there has not been any such bona fide user, or that there has been no such bona fide user during the five years preceding the application. Non-user may be excused if proved to be owing to special circumstances and not to any intention not to use or to abandon the use of the mark (s. 37). (See *re Hare's Trade Mark*, 1907, 24 R.P.C. 263).

The register may be rectified by order of the court on the application of any person aggrieved, or in the case of fraud in registration or transmission of the mark on the application of the registrar. The powers of rectification include correcting or expunging wrong entries, supplying errors and omissions and defects (s. 35).

Effect of Registration.

Registration is effective for 14 years but is renewable (s. 28). The registration if valid gives the proprietor the exclusive right to the use of the mark on or in connexion with the goods in respect of which it is registered (1905, s. 39). This rule is subject to the following qualifications. (*a*) Where two or more persons are registered owners of the same or substantially the same mark in respect of the same goods, no one of them shall as against any other of them have any right of exclusive user except so far as their respective rights have been defined by the court. (*b*) Registration of a trade mark does not entitle the proprietor to interfere with or restrain the user by any person of a similar mark upon or in connexion with goods upon or in connexion with which such person has by himself or his predecessors in business continuously used such trade mark from a date anterior to the use of the mark by the registered proprietor, or to object to the registration of the other man's similar mark for concurrent user.

In all legal proceedings relating to a registered trade mark registration is prima facie evidence of validity, and after seven years from the original registration, or seven years from the passing of the act of 1905, whichever shall last happen, the original registration shall be taken to be valid in all respects unless it was obtained by fraud, or the mark offends against s. 11 of the act. This provision as to validity limits the power which formerly existed of getting rid of long registered marks by proceedings to rectify the register.

Registered trade marks are assignable and transmissible only with the goodwill of the business concerned in the goods for which they are registered, and are determinable with the goodwill (s. 22). Associated marks are assignable and transmissible only as a whole and not separately (s. 27). The owner of a registered mark may assign the right to use his registered mark in any British possession or protectorate or foreign country in connexion with any goods for which it is registered, together with the goodwill of the business therein of such goods (s. 22). Provision is made for apportioning marks where the goodwill of a business by dissolution of partnership or otherwise does not pass to a single successor (s. 23).

The assignments, &c., on proof of title, are recorded on the register (s. 33). It is a condition precedent to an action for the infringement of a new trade mark that the plaintiff should be the registered proprietor of the mark at the time when the action comes on for hearing. This last provision does not apply to an action for "passing-off" (*vide infra*). In actions for infringement, evidence of passing off, or that the infringing mark is calculated to deceive, is not necessary. The court decides on the probability of deception by inspecting and comparing the marks (*Hennessy* v. *Keating*, 1907, 24 R.P.C. 485).

In the case of an old mark in use before the 14th of August 1875 proceedings may be taken if registration under the act of 1907 has been refused (s. 42).

The right to a trade mark lapses if the mark ceases to be distinctive and becomes *publici juris*; if it is separated from the goodwill (a trade mark can only be assigned with the goodwill); if the mark is applied by the trader to spurious goods (as where boxes of cigarettes were so labelled, in conformity with an alleged custom of the trade, as to indicate that they were of Russian manufacture, which was not the fact; or when the mark is abandoned); (temporary disuse, however, is not abandonment unless the mark has in the meantime become associated with the goods of another trader); or where, as in the "linoleum" case (7 Ch. D. 834) it has become the name of the goods, and so merely descriptive; or after fourteen years where registration is not renewed. In dealing with a claim for infringement the court must admit evidence of the usages of trade as to the get-up of the goods for which the mark is registered, and of any trade marks or get-up legitimately used with such goods by other persons (s. 43).

Appeals, &c.

The registrar has an uncontrolled discretion in the administration of the act, except in those cases in which an appeal is given from his acts or refusals to the court or the board of trade (ss. 53, 54). In cases of difficulty he consults the law officers (s. 56).

Actions or other proceedings with relation to trade marks, so far as they are for the court, may be brought in the High Court of Justice in England or Ireland and in the Court of Session in Scotland (ss. 3, 69). In the case of marks registered on application at the Manchester branch, the chancery court of Lancaster has concurrent jurisdiction with the High Court (s. 71). Actions for infringement of a trade mark are not within the jurisdiction of the county court (*Bow* v. *Hart*, 1905, 1 K.B. 592). An annual report is made by the comptroller-general of patents, &c., as to proceedings with reference to trade marks.

III. "*Passing-off*" *and Trade Name.*—A trader has generally, besides his trade mark, numerous other symbols, which he uses as *indicia* of his goods, *e.g.* the name of title under which he himself trades, the name under which his goods are known and sold, badges of property which are termed "trade name," and the distinctive "get-up" of the goods as they appear in the market. These symbols enjoy the protection of the law, under certain conditions, equally with trade marks. No trader is entitled to "pass off" his goods as those of another, and if he infringes this rule he is liable to an action for an injunction and damages, and these rights are preserved by the Trade Marks Act 1905 (s. 45). The right to be protected against "passing-off" is restricted to goods of the same description as those upon which the trader uses the "get-up," &c., imitated. Even if the "passing-off" is done innocently it will be restrained (*Millington* v. *Fox*, 1838, 3 Mylne and Craig, 338). This case is described as not one of the use of a properly descriptive name, but rather a case of the same class as those in which a fancy or invented name is used (*Cellular Clothing Co.* v. *Maxton*, 1899, App. Cas. 326, 341). Although the first purchaser is not deceived, still if the article delivered to him bears words or marks such that it is "calculated to deceive" a purchaser from him, the use of them is illegal.

To this general rule there are several exceptions:—

1. No monopoly is allowed in names that are merely descriptive. But words which prima facie are descriptive, such as "camel-hair belting," for belting made of camel-hair (*Reddaway* v. *Banham*,

1896, App. Cas. 199), or "Stone Ales" for ales brewed at Stone (*Montgomery* v. *Thompson*, 1891, App. Cas. 217), may be shown to have acquired by long use a "secondary distinctive meaning," and, in fact, to mean the goods of a particular trader. And where a defendant is not selling the genuine goods indicated by the name, as where the composition of the goods is a secret, even if the name might otherwise be taken as merely that of the goods, he cannot rely on the defence that the name is descriptive (*Birmingham Vinegar Co.* v. *Powell*, 1897, App. Cas. 710; the "Yorkshire Relish Case"). If, however, the primary meaning of the word is simple and well known, it is extremely difficult to establish a secondary meaning exclusive of the primary one (*Hommel* v. *Bauer & Co.*, 1905, 22 R.P.C. 43; "Haematogen," a preparation for forming blood, secondary meaning not established; cf. *Fells* v. *Hedley & Co.*, 1904, 21 R.P.C. 91; "Naphtha soap," secondary meaning not established; *Wurm* v. *Webster & Girling*, 1904, 21 R.P.C. 373; "White Viennese Band," secondary meaning not established; *Cellular Clothing Co.* v. *Maxton*, 1899, A.C. 326, "cellular" as applied to cloth, secondary meaning not established). But although a name may not, owing to the fact that it consists of well-known or descriptive words, be inherently entitled to protection, a distinctive scroll or device, in which it is embodied, may be so. Thus, in a case (*Weingarten Brothers* v. *Bayer & Co.*, 1905, 21 Times L.R. 418; and see 19 Times L.R. 604) which sharply divided judicial opinion in England, the defendants were restrained from selling corsets in boxes bearing the name "Erect Form Corsets" scrolled thereon by the plaintiffs in a distinctive manner. No monopoly, of course, could be claimed in the words, but it was otherwise with the scroll. The use of a fancy name "iron oxide tablets" has been restrained where it was found likely to cause deception as being used to supersede in the market certain well-known "Iron Ox" tablets (*Iron Ox Remedy Co.* v. *Co-operative Wholesale Society Ltd.*, 1907, 24 R.P.C. 425). (2) A trader cannot be prevented from trading under his own name, if he is using it honestly (bona fide); even though from its similarity to the name of another trader—even one previously well-established—it may injure the business of the latter (*Burgess* v. *Burgess*, 1853, 3 De Gex, M. & G. 896; *Turton* v. *Turton*, 1889, 42 Ch. D. 128; *Dunlop Pneumatic Tyre Co.* v. *Dunlop Motor Co.*, 1907, App. Cas. 430). This right is recognized by the Trade Marks Act 1905, s. 44, which provides that registration of a trade mark under the act shall not interfere with any bona fide use by any person of his own name or place of business or that of any of his predecessors in business. But if a trader has never carried on such a business on his own account or in partnership with others, he cannot, by promoting and registering a joint-stock company with a title of which his name forms part, confer on the company the rights which he as an individual possesses in the use of his name (*Fine Cotton Spinners, &c., Association Ltd. and John Cash & Sons Ltd.* v. *Harwood Cash & Co. Ltd.*, 1907, 2 Ch. 184). If a trader's own name has, before he entered the trade, become the trade name of some other person's goods, he would probably not be allowed to use it without taking steps to prevent deception. This rule does not debar him from using "any bona fide description of the character or quality of his goods" (1905, s. 44). A name can become universally known as referring to the goods of a particular maker, *i.e.* as having a secondary meaning. This does not give exclusive rights to use of the name, but only to prevent other firms from using the goods so as to pass off their goods as those of the person whose name is in question (*Joseph Rodgers & Sons Ltd.* v. *Hearnshaw*, 1906, 23 R.P.C. 348).

It is provided by the Companies Act 1862 (s. 20), that no company shall be registered under a name identical with that by which a subsisting company is already registered, or so nearly resembling it as to be calculated to deceive, unless the subsisting company is in process of being wound up and consents to such registration; and provision is also made for a change of the name of any company which, through inadvertence or otherwise, is registered under a name coming within the statutory prohibition. It is to be observed (cf. Buckley, *Companies Acts*, 8th ed. p. 27) that (*a*) the Companies Act 1862 applies only to the case of taking the name of a subsisting company already registered, and not to a case where a new company proposes to register in the name of, or in a name closely resembling, the name of an old-established company which is not registered, or of a firm or individual trader; (*b*) that as soon as the new company is registered the act ceases to apply; and (*c*) that the act forbids registration irrespectively of the question whether the business proposed to be carried on by the new company is the same as that of the subsisting company or not. But the provisions of the Companies Act on this subject are merely supplemental to the common law, and any company trading in the United Kingdom may restrain persons from registering a new company to carry on a rival business under a name identical with or so similar as to be calculated to deceive, and a company already registered under such a name may be restrained from carrying on a rival business under it. The right to interfere depends not upon fraud but upon the tendency of the similarity to cause confusion, deception or mistake (Fine Cotton Spinners case above cited; *Birmingham Small Arms Co.* v. *Webb*, 1907, 24 R.P.C. 27; *Star Cycle Co.* v. *Frankenburgs*, 1907, 24 R.P.C. 405; *re Reddaway & Co.*, 1907, 24 R.P.C. 203). In such proceedings evidence is admissible to show how the existing company has used the name, and what, by reason of its connecting that name with its goods, the public have come to attribute to it (*Daimler Motor Car Co.* v. *London Daimler Co.*, 1907, 24 R.P.C. 379). A new company will not be allowed to take the whole name of a subsisting company, even although that name is of a descriptive character (*Manchester Brewery Co. Ltd.* v. *North Cheshire and Manchester Brewery Co. Ltd.*, 1899, App. Cas. 83).

Rights of Assignees.

The purchaser of the goodwill of a business has the right to use the trade name under which the business is known, and to restrain others from using it or such imitations of it as may mislead the public. But he is not entitled by the use of the trade name to make the vendor liable, under the doctrine of "holding out," for debts of the business incurred after the sale. And if the vendor of the goodwill gave his name to the business, he cannot (in the absence of any restrictive condition in the agreement for sale) be prevented from beginning to trade in his own name again, unless it be shown that in so doing he is attempting to deceive the public into the belief that he is still the owner of the old business. In construing the words "calculated to deceive" (s. 20) the courts will adopt principles closely analogous to those applicable in "passing off" cases in which the question is raised whether a trade name or the description or get-up of a particular class of goods is or is not likely to deceive (*British Vacuum Cleaner Co.* v. *New Vacuum Cleaner Co.*, 1907, 2 Ch. 312; *Aerators Ltd.* v. *Tollett*, 1902, 2 Ch. 319, 324). When the names of the two companies contain terms of common ordinary meaning descriptive of an article, s. 20 will be applied less readily than where the words said to create the confusion are of the character of fancy words relating rather to the maker than the article (Vacuum Cleaner Case).

IV. *Merchandise Marks.*—The first attempt to make the falsification of trade marks a criminal offence was in the Merchandise Marks Act 1862 (25 & 26 Vict. c. 88). That statute provided that the forgery of a trade mark with intent to defraud, and the false application of a trade mark to goods with the like intent, should be misdemeanours, but left upon the prosecutor the burden of establishing the fraudulent intent. The act contained no provision for summary prosecutions, and did not provide for the seizure of falsely-marked goods on importation from abroad. The international convention for the protection of industrial property, made at Paris in 1883, to which Great Britain acceded in 1884, contains a provision that all goods illegally bearing a trade mark or trade name may be seized on importation into those states of the union where the mark or name has a right to legal protection, and that the seizure shall be effected at the request of either the proper public department or of the interested party, pursuant to the internal legislation of each country. The law had to be amended in order to carry out this article in the convention, and the Merchandise Marks Act 1887 was passed to effectuate this object and generally to make better provision for the protection of merchandise. It was subsequently amended in 1891 and 1894. The effect of the provisions of these statutes may be briefly stated. Any person is guilty of an offence, punishable on indictment or summary conviction by fine or imprisonment, who does any of the five following acts, unless he proves as regards the first four of them that he acted without intent to defraud (there is a special defence to No. v. which is noted below): (i). forges any trade mark, or makes, disposes of, or has in his possession for such purpose any die or instrument; (ii.) falsely applies any trade mark or a colourable imitation of any trade mark to goods; (iii.) applies any false trade description to goods; (iv.) causes any of the above offences to be committed; (v.) sells or exposes for sale, or has in his possession for sale, trade or manufacture, any goods or things to which any forged trade mark or false trade description is applied, or any trade mark or colourable imitation of a trade mark is falsely applied, unless *the defendant* proves that, having taken all reasonable precautions, he had no ground to suspect the genuineness of the mark, &c., and also that on demand he gave to the prosecutor all the information in his power as to the person from whom he obtained the goods, &c., or proves that he otherwise acted "innocently." (See *Thwaites & Co.* v. *McEvilly*, 1903, 20 R.P.C. 663).

"Trade description" is defined as any descriptive statement or other indication as to the measurement, quantity (not *quality*, it should be observed), or weight, place or mode of production, or the material of the goods, or as to their being subject to an existing patent, privilege or copyright; conventional or customary descriptions lawfully in use in August 1887 to indicate that the goods are of a particular class or method of manufacture are allowed to be continued; but if they contain the name of a place and are calculated to mislead as to the real place of production, the name of the latter must be added. The test of what is a trade description depends upon the understanding of the trade and not on scientific correctness (*Fowler* v. *Cripps*, 1906, 1 K.B. 16).

Trade Description.

On a prosecution for any of these offences, there is a power to forfeit the things found although no one is convicted. If the offender is indicted (it is in his option to be tried in this way) the punishment is fine and imprisonment, the latter not to exceed two years. On summary conviction the punishment is not to exceed, for a first offence, four months' imprisonment, with or without hard labour, and a fine of £20; and for any subsequent offence six months' imprisonment and a fine of £50. The importation is forbidden of goods by means of or in relation to which an offence against the acts has been committed, and also of all goods of foreign manufacture bearing any name or trade name being or purporting to be that of a manufacturer or trader within the country, unless it be accompanied by a definite indication of the country where the goods were made or produced. There are also special provisions with regard to the marking of catch-cases. The commissioners of customs have power to make general orders for carrying out the Merchandise Marks Acts. (See Regulations of the 1st of December 1887, Stat. R. & O. Revised, 1904, vol. viii. tit. Merchandise Marks.) Prosecutions may be undertaken by the board of trade in cases appearing to affect the general interests of the country or of a section of the community, or of a trade, subject to regulations made on the 21st of May 1892; and the board of agriculture and fisheries has a like power in the case of the produce of agriculture, horticulture and fisheries [act of 1894, s. 1; Board of Agriculture and Fisheries Act 1903, s. 1 (8); see the regulations of the 27th of October 1894, Stat. R. & O. Revised, vol. viii. tit. Merchandise Marks.]. Under the Sale of Food and Drugs Act 1899, and the Butter and Margarine Act 1907, the importation, except in containers showing their character, of margarine, margarine cheese, adulterated or impoverished butter, milk-blended butter or condensed, separated or skimmed milk, is penalized, and it is provided that the commissioners of customs, in accordance with directions given by the treasury after consultation with the board of agriculture, shall take such samples of consignments of imported articles of food as may be necessary for the enforcement of the law.

V. International Arrangements.—(The Trade Marks Act 1905 applies to the British Islands.) By the international convention for the protection of industrial property (see PATENTS), which was signed at Paris in 1883, the signatory states (others have since acceded) agreed that the subjects or citizens of each state should, in all the other states, enjoy as regards trade marks and trade names the advantages that their respective laws then granted, or should thereafter grant, to their own subjects or citizens. So far as Great Britain is concerned the provisions made for carrying out this convention are contained in s. 65 of the Trade Marks Act 1905 and in s. 91 of the Patents and Designs Act 1907.[1] The effect of that section is to confer on an applicant for the protection of a trade mark in one of the other contracting states a priority over other applicants for registration in the United Kingdom during the space of four months. The section does not, however, exempt the applicant from the conditions and formalities incumbent on ordinary applicants for registration in Great Britain; nor does the fact that the foreign application has been successful of itself give the applicant a right to have his mark accepted for registration. Under the Convention of Madrid of the 14th of April 1891 (to which Great Britain is not a party) a trade mark may be registered as the result of a single application in the countries of all the signatory powers. Besides the general international conventions there are also particular arrangements between many states, *e.g.* Germany and Italy (Italian law of the 24th of December 1903). Guatemala and Salvador, also signatory parties, have withdrawn from the convention.

The following is a list of the British orders in council that have been issued, applying to foreign countries, s. 103 of the Patents, &c., Act 1883:—

Foreign State.	Date of Order in Council.
Belgium	June 26, 1884.
Brazil	June 26, 1884.
Cuba	January 12, 1905.
Denmark (including the Faroe Islands)	November 20, 1894.
Dominican Republic	October 21, 1890.
Ecuador	May 16, 1893.
France	June 26, 1884.
Germany	October 9, 1903.
Greece	October 15, 1894.
Honduras	September 26, 1901.
Italy	June 26, 1884.
Japan	October 7, 1899.
Mexico	May 28, 1889.
Netherlands	June 26, 1884.
" (East Indian Colonies)	November 17, 1888.
" (Curaçoa and Surinam)	May 17, 1890.
Norway (and Sweden)	July 9, 1885.
Paraguay	September 24, 1886.
Portugal	June 26, 1884.
Rumania	August 5, 1892.
Servia	June 26, 1884.
Spain	June 26, 1884.
Sweden (and Norway)	July 9, 1885.
Switzerland	June 26, 1884.
Tunis	June 26, 1884.
United States	July 12, 1887.[2]
Uruguay	September 24, 1886.

All these orders in council are printed in the Statutory Rules and Orders Revised (ed. 1904), vol. ix., under the title "Patents, &c." By orders in council, made under the provisions of the Foreign Jurisdiction Acts, penalties have been imposed on British subjects committing offences against the Patents, &c., Act 1883–1888 (now represented by the Trade Marks Act 1905, and the Patents and Designs Act 1907) and the orders in council issued thereunder, and the Merchandise Marks Act 1887: China and Corea (1904), Egypt (1899), Morocco (1889), Muscat (1904), Ottoman Empire (1899), Persia, Persian coast and islands (1889–1901), Siam (1906) and Zanzibar (1906).

By s. 91 of the Patents and Designs Act 1907,[3] and s. 65 of the Trade Marks Act 1905, the king is empowered by order in council to apply the provisions of s. 91 above mentioned, with such variations or additions as may seem fit, to any British possession. The following is a list of the orders in council that have been issued:—

British Possessions.	Date of Order in Council.
Ceylon	August 7, 1905.
New Zealand	February 8, 1890.
Trinidad and Tobago	August 12, 1907.
Australia (Commonwealth)	August 12, 1907.

The orders in council up to 1903 are printed in the Statutory Rules and Orders Revised (ed. 1904), vol. ix., under the title "Patents, &c."

It should be added that the protection of the Merchandise Marks Act 1887, extends to any trade mark which, either with or without registration, is protected by law in any British possession or foreign state to which the provisions of s. 103 of the act of 1883 or s. 91 of the act of 1907 are, under order in council, for the time being applicable.

A foreigner suing in the United Kingdom for infringement of a trade mark, or for "passing off," is in the same position as a subject.

VI. *Colonial and Foreign Trade Mark Laws.*—The British colonies generally follow the model of the English Trade Marks Acts (1883–1888).

Australia.—Legislation on trade marks is one of the subjects which the Commonwealth of Australia Constitution Act 1900 (s. 9, pt. v. 51, xviii.) places within the exclusive competence of the Federal Parliament. By the Commonwealth Trade Marks Act 1905, s. 20, provision is made for registration of trade marks throughout the Commonwealth, and subject to this act and other Commonwealth legislation the common law of England as to trade marks is applied throughout the Commonwealth. Prior to this act most of the states had their own trade mark law (New South Wales, No. 19 of 1900; Tasmania, No. 9 of 1893; Victoria, No. 1146, 1890; Western Australia, Nos. 7

[1] This section supersedes ss. 103, 104 of the Patents, &c., Act 1883. The references to these sections in the Trade Marks Act 1905 must now be read as applying to s. 91 of the Patents, &c., Act 1907.

[2] A treaty was also concluded between Great Britain and the United States on the 24th of October 1877, for the protection of trade marks.

[3] This section re-enacts the provisions of ss. 103, 104 of the Patents, &c., Act 1883.

of 1884, 5 of 1886, 4 of 1894). But the state Trade Marks Acts, with certain savings, cease to apply to trade marks (1905, s. 6).

The Commonwealth act contains certain novel provisions:—

1. As to a Commonwealth trade mark to be applied to all goods included in or specified by a resolution passed by both houses, that in their opinion the conditions as to the remuneration of labour in connexion with their manufacture are fair and reasonable (s. 78). The mark consists in a device or label bearing the words "Australian Labour Conditions."

2. As to workers' trade marks intended to protect the products of any individual Australian worker or association of such workers other than primary products of agricultural or pastoral industries (s. 74). Sections 115, 116 of the act contain provisions for international and intercolonial arrangements as to protection of trade marks based on ss. 103, 104 of the act of 1883. By the Commerce Trade Descriptions Act, No. 16 of 1905, the import into and export from Australia of falsely marked goods is prohibited.

In *Canada* the law as to trade marks (*Rev. Stats.* c. 63) and merchandise marks (c. 41 of 1888) has been regulated by Dominion acts, similar to English statute law. *New Zealand* has an act of 1889. The *Hong-Kong* ordinance, No. 18 of 1898, is a typical instance of an ordinance in a Crown colony [see also Ceylon, No. 9 of 1906, Jamaica (laws 17 of 1888 and 6 of 1889)]. In the *Bahamas* a trade marks law was passed on the 29th of May 1906, based on the imperial act of 1905. In the *Straits Settlements* there is no registration of trade marks, but the common law as to "passing off" is applied.

United States.—Provision for the registration of trade marks in the United States was first made by an act of Congress of 1870; but that enactment was subsequently declared invalid by the Supreme Court (*U.S.* v. *Steffens*, 1879, 100 U.S. 82), on the ground that the constitution of the United States did not authorize legislation by Congress on the subject of trade marks, except such as had been actually used in commerce with foreign nations or with the Indian tribes. Congress legislated again on the subject in 1881 (act of the 3rd of March 1881, Revised Stats. U.S. ss. 4937–4947). The act of 1881 was repealed by an act of the 20th of February 1905 (s. 592), which, as modified by an act of the 4th of May 1906, now regulates the subject. A trade mark may be registered by the owner if he is domiciled within the United States, including all territory under the jurisdiction and control of the United States (s. 29), or resides or is located in any foreign country which by treaty, convention or law affords similar privileges to citizens of the United States (s. 1).

The right of persons domiciled in the United States was in 1906 extended to owners of trade marks who have a factory in the United States, so far as concerns the registration, &c., of trade marks used in the products of the factory (1906, s. 3). To obtain registration the owner of the mark (whether firm, corporation, association or natural person) must file in the patent office an application (*a*) specifying the name, domicile, location and citizenship of the applicant; (*b*) stating the class of merchandise and the particular description of goods in the class to which the mark is appropriated;[1] (*c*) annexing a drawing of the trade mark and as many specimens as may be required by the commissioner of patents; (*d*) giving a description of the trade mark (only when needed to express colours not shown in the drawing); and (*e*) specifying the mode in which the mark is applied and affixed to goods; (*f*) stating the time during which the m rk has been used (1906, c. 2081, s. 1).

The application must be accompanied by a fee of $10, and be supported by a sworn declaration verifying the ownership and the drawing and description and stating that no one else has a right to use the mark, nor one so like it as might be calculated to deceive, and that the mark is in use in commerce among the several states or with foreign countries or with Indian tribes (1905 c. 592, s. 2).

Where the applicant resides or is located in a foreign country he must also show that the mark is registered in the foreign country, or that application has been made to register it there. Registration on behalf of foreign registrants is not made until foreign registration is proved nor unless application for United States registration is made within four months of the application abroad (1905, *c.* 592, ss. 2, 4).

The United States policy is to require registration of all trade marks unless they (*a*) consist of or comprise scandalous or immoral matter; (*b*) consist of or comprise the flag or insignia of the United States, or of any state or municipality, or of any foreign nation; (*c*) are identical with another known or registered trade mark owned and used by another and appropriated to merchandise of the same description, or so nearly resemble such other marks as to be likely to cause confusion or mistake in the mind of the public or to deceive purchasers; (*d*) consist merely in the name of an individual, firm, corporation or association, unless it is written, printed, impressed or woven in a particular or distinctive manner, or is associated with a portrait of the individual; (*e*) consist merely in words or devices descriptive of the goods with which they are used, or of the character or quality of such goods, or merely of a geographical name or term; (*f*) contain the portrait of a living individual unless his consent is evidenced by an instrument in writing.

Old marks may be registered irrespective of the above rules, no proof that they have been actually and exclusively used as a trade mark of the applicant or his predecessors from whom he derived title in such commerce as aforesaid for ten years before the 20th of April 1905. Applications made in proper form with the prescribed fee are at once examined in the patent office and if in order are gazetted to give opportunity for "interference."

Decisions of the examiners on applications or oppositions are subject to appeal to the commissioner of patents, and from him to the court of appeals for the District of Columbia (ss. 8, 9). The general jurisdiction in trade mark cases is given to the Federal courts below the Supreme Court, which has power by certiorari to review the decisions of circuit courts of appeal upon such cases (ss. 17, 18). The maximum protection given by registration is twenty years. The protection given to marks already registered in a foreign country lapses when the mark ceases to be protected in the foreign country (s. 12). Certificates of registration are issued under the seal of the patent office.

Provision is made to prevent importation of merchandise which copies or simulates the name of any domestic manufacture, manufacturer or trader, or of a manufacturer or trader located in a country affording like privileges to the United States, or which copies or simulates the trade mark registered in the United States, or which bears names or marks calculated to create the belief that it is made in the United States, or in any country other than the true country of origin. United States traders who seek protection can have their names and marks recorded and communicated to the customs department (s. 27). At any time during the six months prior to the expiry of the term of twenty years the registration may be renewed on the same terms and for a like period. The right to the use of any registered trade mark is assignable (with the goodwill of the business in which it is used) by an instrument in writing; and provision is made for recording such instruments in the patent office (s. 10).

France.—In France (laws of the 23rd of June 1857, and the 3rd of March 1890) trade marks are optional, but may be declared compulsory for certain specified articles by decrees in the form of administrative orders. The decrees regulating registration are of the 27th of February 1891 and the 17th of December 1892. The following are considered trade marks: names of a distinctive character, appellations, emblems, imprints, stamps, seals, vignettes, reliefs, letters, numbers, wrappers and every other sign serving to distinguish the products of a manufacture or the articles of a trade. A fixed fee of one franc is charged for entering the minute by registration (dépôt) of each mark, and making a copy thereof, exclusive of stamp and registration fees. By legislation of the 1st of August 1905 and the 11th of July 1906 provision is made for marking certain classes of commodities, mainly food products, to prevent falsification and the sale of foreign products as French.

Germany.—Under the German trade mark law of the 12th of May 1894 any person whatsoever can acquire protection for a trade mark, and all foreigners in Germany are placed on an exactly equal footing with Germans in the eyes of the law, so long as they have a domicile (*Niederlassung*) within the empire, *i.e.* a place of business or a residence which involves the payment of German taxes. The registration of a trade mark expires *ipso facto* after ten years from its date, but may be renewed for a similar period. Germany acceded to the international convention on the 1st of May 1903.

In the *Netherlands* (law of the 30th of September 1893) two distinct forms of registration are in force: (*a*) registration merely for the Netherlands; (*b*) international registration, available for the states of the international union.

The following other foreign trade mark laws may also be noted: *Austria-Hungary*, law of 1890 (published in Vienna on the 6th of January and in Budapest on the 6th of April 1890), and amending law of the 30th of July 1895, which enactment protects additions to trade marks. *Denmark* (law of the 11th of April 1890, and an amending law of the 19th of December 1898, which enables traders to register words or figures, provided that these are not indicative of the origin, kind, use, quality or price of the goods). *Japan* (law of the 1st of July, and regulations of the 20th of July 1899). *Russia* (law

[1] By the law of 1906 (s. 21) the commissioner of patents is directed to establish classes of merchandise.

of the 26th of February [9th of March] 1896). *Switzerland* (law of the 26th of September 1890).

AUTHORITIES.—Sebastian, *Trade Marks* (4th ed., London, 1899; in this work the American cases are fully dealt with); Kerly, *Trade Marks* (London, 3rd ed., 1908); Kerly and Underhay, *Trade Marks Act 1905* (London, 1906); Cartmell's *Digest* (London, 1876–1892); Sebastian, *Digest* (London; cases down to 1879); Gray, *Merchandise Marks Act* (London, 1888); Safford, *Merchandise Marks* (London, 1893). The reports of the Departmental Committee of 1887, and of the Select Committees of the House of Commons appointed in 1887 and 1890 to consider the law with regard to merchandise marks and false marks, and the annual Reports of the Comptroller-General, throw great light on both the history and the practical working of the law. For American law, see Browne, *Treatise on Trade Marks* (Boston, 1873); Cox, *American Trade Mark Cases* (Cincinnati, 1871); *Manual of Trade Mark Cases* (Boston, 1881); Greeley, *Foreign Patents and Trade Marks* (Washington, 1899); Paul, *Law of Trade Marks* (St. Paul, Minn., 1903); and the reports of the commissioner of patents. As to foreign trade mark laws generally, see the following: *British Parl. Papers; Reports relative to Legislation in Foreign Countries* (1879; Cd. 2284, 2420); *Reports from H.M.'s Representatives Abroad, on Trade Marks, Laws and Regulations* (1900; Cd. 104); *Summaries of Foreign and Colonial Laws as to Merchandise Marks* (1900; Cd. 358, p. 850 seq.).

(A. W. R.; W. F. C.)

TRADE ORGANIZATION. The development of commercial organization which attended the growth of trade and industry during the 19th century assumed two distinct phases. In the first we see the creation of associations of persons engaged in trade and industry for the purpose of protecting their interests and of facilitating and fostering commercial relations. In the second, governments elaborate departmental organizations for the supervision of commerial matters, and utilize their consular services as means of commercial intelligence and influence.

The associations belonging to the first category comprise three classes:—

a. Those which are themselves engaged in trade, like ordinary joint-stock companies, or which result from the combination of firms or individuals in the same or connected trades, for the purpose of facilitating or restricting production, limiting competition, regulating prices, &c.

b. Those which, without engaging in trade, aim at providing facilities for the transaction of commercial or financial operations. They chiefly take the form of exchanges, bourses, public sale rooms, &c., such as the Baltic, Lloyd's, the Stock Exchange, the Corn and Coal Exchanges, the Commercial Sale Rooms.

c. Non-trading bodies, in the nature of public institutions, whose objects are to protect the interests of trade.

When, at the close of the 18th century and early in the 19th, the power of the old trade gilds and corporations of merchants had been broken, both governments and commercial men soon realized that the ancient societies would not follow the commercial evolution, and that new organizations must be created to meet new requirements. Two systems were evolved, which, from their prototypes, are known as the British and the French systems. In the former, trade organizations were left to develop themselves in their own way, and in whatever direction they might think fit, without any official interference. In the latter, on the contrary, the government constituted itself the creator of trade organizations, which it incorporated into the administrative system of the country, and to which it gave an official status as an integral part of the machinery of the state. The former have grown chiefly into associations for the promotion and defence of commercial interests, whilst the latter have mainly become sources of commercial information and means of action at the disposal of the government. While organizations on the British system are, as regards the government, purely advisory bodies whose opinion might or might not be asked in connexion with commercial matters, and whose duties are limited to the services which they are in a position to render to their members and to commerce generally, organizations on the French system not only must be consulted, in certain specified cases, by the government, especially in connexion with the drafting of commercial legislation and of regulations affecting trade, but they have also administrative duties to perform, such as the control of public commercial institutions, of testing, standardizing and conditioning establishments, port and dock works, &c. The British system obtains in the United Kingdom and the British colonies, in the United States and in Belgium, while the French has been adopted in most European countries, and in Japan.

British and French Systems.

I.—Great Britain and Colonies

A.—*Commercial Associations.*

In the United Kingdom commercial associations arose with the growth of trade, without any assistance from the state and free from all government restriction or control. The first in point of date were the "commercial societies" which were formed, chiefly during the last quarter of the 18th century, in Birmingham, Exeter, Halifax, Leeds, Liverpool and Manchester, and which exercised a not unimportant influence upon commercial developments at the close of the 18th and in the early years of the 19th centuries. The modern associations which superseded them divided themselves into four classes, viz:—

a. Chambers of commerce and associations which aim at becoming representative of general commercial interests;

b. Associations or institutes which represent particular trades or branches of trades;

c. Trade protection societies, which look after the interests of retail as well as wholesale traders, and undertake to supply them with information as to the standing and credit of firms, expose swindlers, collect debts, &c.; and

d. Non-representative associations rendering general commercial services.

a. Chambers of Commerce and General Associations.—Most of the chambers of commerce in the United Kingdom were formed during the latter half of the 19th century, although a few were in existence much earlier. The oldest British chamber is the Jersey chamber, which dates from 1768. The Glasgow chamber was founded in 1783. Dublin followed in 1785, Edinburgh in 1786, Manchester in 1794, Belfast in 1796, Birmingham in 1813, Newcastle-upon-Tyne in 1818, Liverpool in 1851, Sheffield in 1857, &c. The London chamber was the last of the chambers of importance to be established; it dates only from 1881.

The London Chamber.

The London Chamber of Commerce, which has over 3000 members, is one of the most representative associations of its kind, and the organization adopted has been very effective in securing this. The chamber has been divided into trade sections, of which there are at present forty-four, and members specify the sections to which they desire to belong. Each section has a separate organization, and is presided over by a chairman elected by itself, who may be helped by an elected committee if found advisable. The general council of the chamber confirms the election of chairmen of sections, and no action can be taken by the chamber on the recommendation of a section without authorization of the council. The chamber has placed itself in connexion with a number of mercantile associations which, whilst preserving their separate organizations and their independence of action, have found it advantageous to work in conjunction with it, either for general or for particular purposes, and to have a voice in its council. The more important of these are the Institute of Bankers, the Institute of Chartered Accountants, the Society of Accountants and Auditors, the General Ship Owners' Society, the General Produce Brokers' Association, the Federation of Grocers' Associations of the United Kingdom, the West India Committee, the Corn Trade Association, the United Planters' Association of Southern India, &c.

The Liverpool Chamber.

Particular reference should also be made to the Liverpool chamber, which, as regards division into trade sections and co-operation with independent associations, works on similar lines to those of the London chamber. The African trade section of the Liverpool chamber has been prominent in connexion with African questions, and since its foundation in 1884 has been the leading voice in all matters relating to West Africa.

Association of Chambers of Commerce.

The Association of Chambers of Commerce of the United Kingdom, which was formed in 1860, contributed much to give chambers of commerce as a whole a national importance. This association, like the chambers themselves, was of course purely voluntary, and at its foundation only sixteen chambers decided to join it. The association is maintained by an annual subscription from the constituent chambers. It has been instrumental in passing many useful acts of parliament, and in otherwise influencing legislation upon commercial topics. The general meetings, which are held annually in March, in London, and at which delegates are present from all parts of the country, have come to be considered as a kind of parliament of trade, and representatives of the Board of Trade, the general post office, and the foreign and colonial offices are generally in attendance. Special meetings take place in September, and are held in provincial towns on the invitation of the local chamber.

The association has limited its work to the United Kingdom, and has not taken advantage of the commercial development of the colonies to afford colonial interests an opportunity of voicing their needs in the metropolis. To supply this need the London Chamber of Commerce has, from time to time, organized congresses of chambers of commerce of the empire. Some of these congresses have been held in the colonies, the first being at Montreal in 1903.

British Chambers Abroad.

The home organization of chambers of commerce is supplemented by a few British chambers which have been established in foreign countries. These institutions are self-supporting, and not, as seems often to be thought, branches of, or subsidized or controlled by home chambers. The British Chamber of Commerce in Paris, which is the oldest of them, dates from 1873, and was originally established by British merchants in Paris for the defence of their own trade interests. Its scope soon extended, however, and it admitted to membership British firms trading with France although not resident in France, and in course of time became representative of general British commercial interests in the French markets. Other British chambers are to be found in Genoa, Alexandria, Barcelona, Constantinople and St Petersburg. In Brussels an Anglo-American chamber jointly represents British and American interests.

Foreign Chambers in England.

Several countries are represented in London by chambers of commerce, while the American Chamber (Liverpool), the Anglo-Belgian, the Anglo-Portuguese, the Australasian, the Italian, the Norwegian and the Swedish chambers are members of the Association of Chambers of Commerce of the United Kingdom. The United States are represented in England by the American Chamber of Commerce in Liverpool.

Colonial Chambers.

Commercial organization in the colonies is very much on the same footing as it is in the United Kingdom. The most representative associations are the chambers of commerce, whose constitution and functions are similar to those of the British chambers. In *Canada* the chambers, which are also sometimes called Boards of Trade, after the American custom, number over sixty, the most important being the Montreal and Toronto Boards of Trade and the Quebec Chamber of Commerce. The Canadian chambers have no association, but hold periodical conferences. There is, in addition, the Canadian Manufacturers' Association, with headquarters in Toronto and branches in all the provinces, which incorporates all the associations of manufacturers in the Dominion. The *Australian* chambers of commerce, which number some thirty, have joined into an association called the General Council of the Chambers of Commerce of the Commonwealth of Australia. In New Zealand, South Africa, India and many British colonies there are chambers of commerce in all the more important towns.

b. Associations Representing Particular Trades.—Associations representative of particular trades are almost innumerable. The London General Shipowners' Society, the Liverpool Shipowners' Association, the North of England Shipowners' and Steamship Owners' Associations may be mentioned as representative. The chambers of shipping and shipowners' associations joined forces in 1878 in order to establish the Chamber of Shipping of the United Kingdom, which does for them what the Association of Chambers of Commerce does for chambers of commerce. The Iron and Steel Institute affords a means of communication between members of the iron and steel trades, while the British Iron Trade Association is one of the most powerful. The nature of other associations is sufficiently indicated by their titles. In addition there are the Cotton Association, the Drapers' Chamber of Trade, the Fish Trade Association, the Sugar Refiners' Committee, various tea planters' associations, the Oil Seed Association, the Petroleum Defence Committee, the Mansion House Association on Railway and Canal Traffic, &c.

c. Trade Protection Societies.—These seem to be, on the whole, more ancient bodies than chambers of commerce. In the early part of the 19th century they were already strongly organized, especially in the West Riding of Yorkshire. Outside of that district the Dublin Society was the most important. They number more than 100 throughout the United Kingdom.

The Manchester Guardian Society, which dates from 1826, occupies a position of special prominence in the Midlands, and may be taken as the model of such associations. Its objects are—the making of private inquiries as to the respectability and credit of traders, the detection and exposure of swindlers; the collection of debts; the winding-up of insolvent estates; the issue of notices of bills of sale, judgments, bankruptcies, &c.; and generally the improvement of laws and regulations affecting trade. The society has over 6000 members, and its usefulness may be gauged by the fact that it answers an average of 40,000 credit inquiries every year.

Trade protection societies formed themselves, as early as 1848, into an association, which was at first an association of secretaries, but in 1865 was transformed into an association of societies. The association issues a quarterly journal called the *Trade Protection Journal.*

B.—*State Departmental Organizations.*

Although the British government allowed commercial organizations within its jurisdiction to grow independently of official control, it does not follow that it took no interest in the protection and promotion of British trade and the dissemination of commercial intelligence. As long ago as the reign of Charles II. the body which is now the British equivalent of what is known in most countries as the ministry of commerce, viz. the board of trade, was established. The commercial jurisdiction of the Board of Trade does not extend beyond the limits of the United Kingdom, but the Foreign Office, through the negotiation of commercial treaties and by means of the consular body, came into touch with international trade. With the development of the colonies, the colonial and India offices also found themselves called upon to act, to a certain extent, as guardians of commercial rights and channels for the dissemination of commercial intelligence. But when competition began to displace British goods from foreign markets, and when the British trader noticed the efforts which were being made by foreign governments for the promotion of trade, he came to the conclusion that the British government was not doing anything for him.

Consular Service.

Complaints were especially loud against the consuls, who were accused of systematically disregarding commercial interests, whilst their American, German, French and Belgian colleagues did not consider it below their dignity to take advantage of their position, in order to promote the trade of the country they represented. British Consular Reports were also unfavourably compared with those issued by foreign consuls, notably the American. The result was that, in 1886, instructions were issued to the consular service which, for the completeness and fairness with which they deal with the subject, have frequently been quoted as models which might advantageously be followed (see Parliamentary Paper, Commercial, No. 16, 1886). The preparation of consular reports, however, continued to be most unfavourably criticised, and frequent instructions were issued by the foreign office in regard to them. The whole question was raised again in 1896, when, as the result of lengthy communications between the Foreign Office on the one hand, and the Association of Chambers of Commerce and the London chamber on the other, fresh instructions were sent to British consuls, reiterating the instructions of 1886.

The consular service has of late years been supplemented by the appointment of commercial attachés.

Commercial Intelligence Branch of the Board of Trade.

The pressure exercised by the chambers of commerce upon the government led to the appointment in 1897 of a departmental committee on the dissemination of commercial intelligence, which was charged with considering means of more adequately supplying traders with commercial information, of improving consular and colonial reports, and with reporting on the advisability of appointing commercial agents to the colonies and establishing a commercial intelligence office. The chief result of the committee's recommendations was the establishment of the commercial intelligence branch of the Board of Trade. It publishes the *Board of Trade Journal* weekly. Attached to the branch is an advisory committee, composed of representatives of the various government departments and of the Association of Chambers of Commerce.

The scope of the commercial intelligence branch was further increased, and its means of action strengthened, by the transfer of the Imperial Institute to the Board of Trade, which was effected in 1902 by the passing of a private act of parliament.

The self-governing colonies are represented in London by agents-general (*q.v.*), while the commercial interests of the crown colonies are in the hands of the crown agents for the colonies.

II.—United States of America

A.—*Commercial Associations.*

American trade organizations have been developed mainly on the lines of the British system. Of the associations which come within the scope of this article, the most important are the chambers of commerce, which in certain cases are called boards of trade. Theoretically there is a distinction between the two, chambers of commerce being entrusted with the protection of general commercial interests, especially in connexion with foreign trade, whilst boards of trade look after local commercial questions. But in practice the difference is of no importance, as chambers of commerce take cognisance of local as well as international trade matters, and the boards of trade in no way limit the sphere of their activity to purely American questions.

The oldest American commercial organization is the New York Chamber of Commerce, which was founded in 1768, and incorporated by royal charter in 1770. In the words of its charter, its object was "to carry into execution, encourage and promote by just and lawful ways and means such measures as will tend to promote and extend just and lawful commerce." It was the prototype of all the other chambers of commerce and boards of trade which have since been established in the United States, and which are said to exceed 1000 in number. American trade organizations are associated in a National Board of Trade, which corresponds to the Association of Chambers of Commerce of the United Kingdom. The objects of this institution are to secure unity and harmony of action in reference to commercial questions, and to obtain, through its representative character, more satisfactory consideration of the matters which it brings under the notice either of the Federal government or of the local state administrations. The expenses of the National Board of Trade are defrayed out of a fund formed by the subscriptions of the various associations belonging to it. The United States has a number of chambers of commerce established in foreign countries. The first institution of this kind was started so long ago as 1801, when the American Chamber of Commerce in Liverpool was established. This chamber is the only one representing American commercial interests in the United Kingdom, there being no association of this nature in London. The American Chamber of Commerce in Paris is one of the most active, important and representative foreign associations on the continent of Europe. In some places where neither the American nor the British element is strong enough to maintain separate associations (notably in Brussels), they have joined hands to support an Anglo-American Chamber of Commerce, which is found to work fairly satisfactorily. The American commercial museums, although of recent foundation, have attracted much notice owing to the practical and business-like manner in which they are conducted, and are considered to be among the best equipped institutions of this nature. Those in Philadelphia and at San Francisco are the best known. The Philadelphia museum, which came first and is better known, was established by an ordinance of the municipality in 1894, and is supported by subscriptions and by municipal subsidies, administered by a board of trustees, who are appointed for life and serve without remuneration. The work of the museum is supervised by an advisory board, composed of representatives of the principal commercial organizations in the United States. Its objects are to assist American manufacturers and merchants in securing wider foreign markets for their products, to aid them in forming connexions abroad, and to bring foreign buyers in touch with them. One of the chief ways in which this is done is by means of an index file of foreign customers supplied to American manufacturers, and vice versa. In addition to the regular service to members, the museum also maintains abroad, in various cities, index files covering some sixty American trades or trade divisions, containing the names of American manufacturers of standing, with full particulars of their various lines of manufacture. These files are generally entrusted to chambers of commerce, or similar commercial institutions, and are placed gratuitously at the disposal of foreign manufacturers and merchants. The Philadelphia museum has also a most valuable library and a museum of samples.

B.—*State Departmental Organization.*

The American state organization for dealing with commercial matters lacks the theoretical completeness of the organization of most European states, but is nevertheless found to give satisfaction. Official control is exercised through various bureaus placed, for the most part, under the treasury department. The most important of these are: the interstate commerce commission, which deals with matters affecting the inland trade; the industrial commission, which looks chiefly after manufacturing; and the fishery bureau. Foreign commercial matters come within the cognisance of the bureau of foreign commerce, a section of the state department which also controls the consular body, and sees to the publication of their reports and to the dissemination of foreign commercial intelligence. The state department corresponds to the British foreign office.

The Pan-American Union, until 1910 called the Bureau of American Republics, was established in 1889, as a result of the Pan-American Conference called together in that year by the late James G. Blaine, secretary of state at that time. This bureau, which had its office in Washington, is supported by a contribution from all the republics of North, Central and South America, which is fixed at the rate of 1000 dollars a year per million inhabitants. Its object is the dissemination of trustworthy commercial information concerning the republics of the American continent, and in pursuance of this object it has issued a large variety of publications.

The American consular service has been frequently pointed out as a model to be followed in connexion with commercial matters. **Consular Service.** America, contrary to the European practice, has no *consuls de carrière*. Her consular representatives are appointed for a period of, as a rule, four years, and are selected in preference from commercial circles. Their work, as compared with that of British consuls, is rather limited, and they have nothing to monopolize their time like the shipping interests with which the British consular body is entrusted in most countries. Since 1898 the bureau of foreign commerce issues consular reports daily, as fast as they are received, and circulates them in advance sheets, printed on one side of the paper only, like printers' proofs. They are afterwards republished in permanent form.

The American consular body, which numbers some 400 members, and is exclusively composed of American citizens, is distributed according to the commercial importance of towns.

III.—France

A.—*Commercial Associations.*

The French government was the first to elaborate a regular system of trade organizations, which it endeavoured to make as complete as possible. This system comprises:—

a. Chambers of commerce;

b. Consultative chambers of arts and manufactures; and

c. Syndical chambers of trade and industry.

a. Chambers of Commerce.—Chambers of commerce owe their origin to the city of Marseilles, where, in 1599, the town council, which had hitherto looked after the commercial interests of the city, found it no longer possible to combine commercial with municipal functions, and established an association which it called the "Chamber of Commerce" to take up the commercial part of its duties. **Origin.** This seems to be the first time that the title was used. The new chamber soon became a most important body, and in 1650, during the minority of Louis XIV., *lettres patentes* were granted to it. It settled the law merchant and the customs of the port, was entrusted with the appointment of consuls and the control of French consulates in the Levant, fitted out expeditions against corsairs, owned fleets, sent embassies to the Barbaresque countries, organized commercial missions, &c. Its ordinary budget, at one time, amounted to over one million livres. Louis XIV. conceived the idea of a system of organizations which, whilst not being allowed to become so dangerously powerful as that of Marseilles, would nevertheless be useful in other towns, and in 1700 he caused an *arrêté* to be published, ordering the creation of chambers of commerce, which were entrusted with the nomination of deputies to the Royal Council of Commerce which had just been created in Paris. Chambers were consequently established in Lyons, Rouen, Toulouse, Montpellier, Bordeaux, La Rochelle, Lille, Bayonne, Amiens, &c. These bodies, however, did not exercise much influence under the monarchy. Including the Marseilles chamber, they were suppressed, with all trade gilds and other trade associations, in 1789. Napoleon re-established the chambers by decree of the 24th of December 1802, and endowed them with a constitution similar, in essential particulars, to the one they have at present, which has served as a model for chambers of commerce on the Continent, but he submitted them to a uniform and narrow administrative jurisdiction which practically deprived them of all initiative.

They are now regulated by the law of the 9th of April 1898, which codified, altered and completed previous legislation on the subject. **Constitution.** Under this law, chambers of commerce can only be established by a decree countersigned by the minister of commerce, upon the advice of the municipal council of the place where the chamber is to be, of the general council of the department, and of the existing chambers of commerce of the district. The members of chambers of commerce used to be elected by the "Notables Commerçants," who were a body of commercial electors selected by the prefects in accordance with the provisions of the Code of Commerce. They were abolished by law in 1871, but those who were then entitled to the designation still continue to use it, which explains the words "Notable Commerçant," so puzzling to foreigners in French commercial directories and on French business cards. At present, commercial houses paying *patente*—which is a special tax upon people engaged in trade—elect the members of the chamber, the number of whom is fixed for each chamber by the minister of commerce.

Their functions, which are consultative and administrative, are set out in part ii. of the law of 1898. The government is bound to take their opinion regarding the regulation of commercial usages, the establishment of public institutions **Functions.** of a commercial or financial nature, and of tribunals of commerce, the improvement of transport and communications, the application of laws of a local character, the sale price of prison-made goods and the tariff for prison labour, and local public works, and loans or taxation in connexion therewith. On the other hand, they are allowed to submit observations to the government, without being asked, on proposed changes in the commercial or economic legislation of the country; on customs tariffs and regulations; on railway, canal and river rates; and on transport regulations. As regards their administrative functions, they may be authorized to establish and administer such institutions as bonded warehouses, public sale-rooms, fire-arm testing establishments, conditioning rooms for wool, silk, textiles, paper, &c., commercial, professional, or technical schools and museums, &c. They may be granted concessions for public works, and may undertake the carrying out of public services, especially in regard to the ports, docks, canals and navigable rivers in their district, and be authorized to issue loans for the purpose.

Previous to 1898 it was illegal for chambers of commerce to hold joint meetings for the discussion of matters of public interest, and they were not even allowed to correspond or consult in any way, except through the medium of the minister of commerce. The new law relaxed to a certain extent this prohibition, by authorizing direct correspondence and permitting chambers in a district to meet for the joint consideration of questions affecting their district, but for no other purpose. Such a thing as an association of chambers of commerce is still illegal in France.

French Chambers of Commerce Abroad.

When, in 1873, British merchants in Paris started a British chamber of commerce in the French capital, the French government looked rather askance at the new venture, and M. Léon Say, when minister of commerce, even threatened it with forcible dissolution unless the title "Chamber of Commerce" was dropped. This demand was not ultimately pressed, and the services rendered by the British chamber soon opened the eyes of the French government to the advantages which they might derive from the formation of similar institutions to represent French commercial interests abroad. In 1883 the minister of commerce started the organization of such chambers, which endeavoured to combine to a certain extent the French and the British systems.

Foreign Chambers of Commerce in Paris.

Foreign commercial interests are represented in Paris by seven foreign chambers of commerce, of which the British Chamber is the oldest. The others are the American, Austro-Hungarian, Belgian, Italian, Spanish and Russian chambers. In 1896 these chambers formed themselves into an Association of Foreign Chambers of Commerce, but the French government gave it to be understood that, as they did not allow associations of French chambers, they could not treat foreign bodies more favourably, and the association had to be dissolved.

Constitution.

b. Consultative Chambers of Arts and Manufactures.—These institutions, organized somewhat after the model of chambers of commerce, represent manufacturing and industrial interests. They were established by Napoleon I. in 1803, and formed part of the complete system of commercial organizations which he intended to give France. They are now regulated by decrees of 1852 and 1863, and are composed of twelve members elected for six years by merchants and manufacturers inscribed upon an electoral list specially drawn up by the prefects. These chambers, of which there are some fifty in existence, are placed under the control of the minister of commerce, but instead of being kept out of the *patentes*, like chambers of commerce, they are supported by the municipality of the town where they are situated, which has also to provide them with offices rent free, and with clerical assistance.

Functions.

In addition to giving advice in connexion with manufacturing and industrial matters, they have to look after and report upon improvements in manufactures and machinery, new industrial processes, &c. They are especially useful in the preparation of local and international exhibitions. They are also entrusted with the nomination of the Consultative Committee of Arts and Manufactures, a body whose functions are to advise the ministers of commerce and finance, as well as those of the interior and of public works, as regards the regulation of dangerous trades and industries, patents and trade marks legislation, and the interpretation of customs regulations.

c. Syndical Chambers of Trade and Industry.—By the side of the official trade organizations other associations have grown up, which, although regulated by law, are in the nature of voluntary and self-supporting bodies, viz. the syndical chambers of trade and industry. The repeal in 1884 of the law of 1791, which prohibited the formation of trade or professional association, was the signal for the formation of those chambers, which soon acquired great influence. A few syndical chambers existed before that date, the oldest, the Chamber of Master Builders, dating back as far as 1809, but they were only tolerated, and their existence, being illegal, was most precarious.

Constitution.

The syndical chambers, which are divided into chambers of employers and chambers of employed, are the official organs and representatives of the trade and professional syndicates authorized by the law of the 31st of March 1884, which was the work of M. Waldeck-Rousseau. Each syndicate has its separate chamber. They may be established without government authorization, but a copy of their rules and a list of their officials must be sent to the prefect. Membership is strictly limited to persons of French nationality. The only way in which the government can dissolve them is by application to the courts of justice for an order of dissolution on the ground of infringement of the provisions of the law. In Paris, most of the syndical chambers have formed an association called the Union Nationale du Commerce et de l'Industrie—Alliance des Chambres Syndicales. Another association, intended to take up the defence of the interests and rights of syndical chambers, has been formed under the title of Syndicat du Commerce et de l'Industrie—Syndicat des Chambres Syndicales. The syndical chambers are kept up by the subscriptions of their members, and have the right to hold real property, as have also the associations of chambers, which are kept up by subscriptions from the constituent chambers.

Functions.

According to the law which authorized their formation, the objects of the syndical chambers are exclusively "the study and defence of economic, industrial, commercial and agricultural interests," and for this purpose they have complete freedom of intercommunication and can hold congresses. They are authorized to establish for their members mutual benefit societies and pension and relief funds, to open employment agencies, to give legal advice to, and in certain cases to bring actions on behalf of their members, and to organize the settlement of disputes by arbitration. They take part in the election of judges of the tribunals of commerce and of the Conseils de Prud'hommes.

B.—*State Departmental Organization.*

Ministry of Commerce.

The state commercial departments and offices are chiefly centred round the ministry of commerce, to which is assigned the commercial part of the duties fulfilled in England by the board of trade. A ministry of commerce existed for short periods in 1811 and in 1828, but it was ultimately suppressed in 1829, and from that date until 1886, when the department received its present form and separate existence, commerce was only represented in the French government by a subsidiary bureau attached sometimes to one ministry, sometimes to another. The ministry is divided into three main bureaus—the first entrusted with all matters connected with the home trade and industry, the second with foreign and colonial relations, and the third with the compilation of statistics.

Attached to the ministry of commerce is a body called the Conseil Supérieur du Commerce et de l'Industrie, which acts as an advisory council to the minister. Its origin goes back to the council of commerce established by Louis XIV., but it is now regulated by a decree of 1882.

National Office for Foreign Trade.

The Office National du Commerce Extérieur was established by a law of the 4th of March 1898, and is carried on jointly by the ministry of commerce and the chamber of commerce of Paris, the latter having provided it with an installation at a cost of over 1,200,000 francs. The office, which has been founded for the promotion of French trade with foreign countries and the dissemination of commercial intelligence, fulfils duties similar to those of the commercial intelligence branch of the board of trade. It also publishes the weekly *Moniteur officiel du commerce.*

Office Colonial.

The Office Colonial, whose duties are especially to furnish information concerning the French colonies, to promote emigration thither, and to foster a demand in France for the produce of her colonies, was established by a decree of the 14th of March 1899. It is entrusted, in addition, with a permanent exhibition of colonial produce and a museum of samples of goods supplied by or required in the colonies. The office is also in charge of a colonial garden at Vincennes, where experiments are made for the acclimatization of colonial plants and produce in France, and the cultivation of French produce in the colonies. The office publishes a monthly bulletin of miscellaneous colonial information, and issues yearly commercial and other reports dealing with the colonies. It is a dependency of the ministry of the colonies.

Consular Service.

French consuls are instructed to transmit to their government all information which they may consider useful for the prosperity of French trade. It is also their duty to spread, in the country where they reside, a knowledge of such French commercial and financial matters as they may consider most useful in the interests of their own country. The close relations which they are recommended to cultivate with the French commercial community within their jurisdiction through the local French chamber of commerce and the councillors of foreign trade are intended to enable them to keep in better touch with commercial questions. They have had, however, to be frequently reminded of their commercial duties, and the French chambers of commerce have criticized them almost as much as the British chambers have British consuls. The most important instructions issued to consuls were contained in circulars from the minister for foreign affairs dated the 15th of March and the 24th of April 1883. French consuls have to make a return to their government every fortnight—every month if the district is not of great commercial importance—showing, upon forms specially provided, the nature, quantity, origin or destination, prices wholesale and retail, and chief trade marks of the goods imported into and exported from the district, the results of public sales of produce, the conditions of transport, contemplated public works and tenders advertised, state of the labour market, artistic enterprises, commercial failures and rumours concerning important local firms, effect of foreign competition, imitation of French trade marks, &c. These returns are mostly of a confidential nature, and are not intended for publication, but whenever the minister considers it advisable he causes information to be conveyed through the chambers of commerce, or other channels, to the parties chiefly interested. The ordinary consular reports are published in weekly instalments in the *Moniteur officiel du commerce.*

IV. Germany

A.—*Commercial Associations.*

German trade organizations are of three kinds, viz.:—

a. Official organizations established by law, and called Handelskammern, or chamber of commerce;

b. Semi-official associations; and

c. Voluntary or "free" associations.

a. Chambers of Commerce.—Contrary to the idea prevalent in England, official trade organizations in Germany are in a somewhat chaotic state. They have been established under more or less different conditions and systems in each state of the empire, and in certain districts still bear the imprint of foreign origin. They are under the control of the local state governments and lack the homogeneity and unity of direction of the French official system.

Hanseatic Organization.

Before proceeding to a general examination of the German régime, special mention must be made of the chambers of commerce of the old Hanseatic Confederacy which stand apart, and whose duties, as well as constitution, differ from those of trade organizations in the rest of Germany. The chambers of commerce in Hamburg, Bremen and Lübeck are not only the successors of, but (contrary to what happened in Germany as well as in other countries) have been evolved out of the old corporations which looked after the interests of the Hans traders in the olden days, and which, in the case of the Hamburg "Commerz-Deputation," for instance, dated as far back as 1665.

The Hamburg Chamber of Commerce, whose present constitution dates from 1860, is composed of twenty-four members elected for six years by the ancient "Versammlung eines ehrbaren Kaufmannes," that is to say, the merchants and commercial men whose names appear on the register of the "Honest Merchants" of the city. Its income is chiefly derived from special taxation, to which are added the proceeds of the sale of contract and transfer stamps, and also the amount paid every year for the re-registration of each "Honest Merchant." This latter source of income amounts to about 70,000 marks per annum. The chamber has to submit its accounts for approval to the Senate of the Republic.

In addition to the general duties of chambers of commerce in connexion with trade matters, the Hamburg chamber—the same may also be said of the other Hanseatic chambers—fulfils the combined functions of a chamber of shipping and of a port and docks board. It has the right of proposing judges and of nominating experts attached to the courts. The exchanges and public sale rooms of the city are under its control, and it publishes the official quotations, as well as a weekly price list of goods and produce at the port of Hamburg. It is entitled to elect members to the "Bürgerschaft" or lower house of representatives, who are especially competent to deal with trade and shipping questions, customs duties and emigration. The chamber must be consulted by the "Bürgerschaft" with reference to all proposals affecting trade and navigation.

In Bremen the chamber is composed of twenty-four members elected by the "Ausschuss des Kaufmanns-Konvents," which comprises all the important commercial houses of the city. Two members go out every year, and no one can remain a member for more than eighteen years. The Bremen chamber is intimately connected with the Senate of the Republic, a standing committee of both being in existence to settle questions affecting trade and navigation.

The Lübeck chamber is composed of twenty members elected for six years by the associations representing the wholesale and retail trades. The president must be approved by the senate, and is sworn in as a state official. He holds office for two years, and is not paid for his services, but when he goes out of office is presented with a sum of money subscribed by the townspeople. The Lübeck chamber is probably the wealthiest organization of its kind in Germany, and is entrusted with the administration of the property of the old corporation of the "Vorstand der Kaufmannschaft," which is very important. The senate must consult it not only in trade and navigation matters, but also with reference to all contracts entered into on behalf of the state.

Chambers of Commerce.

Chambers of commerce in other parts of the German Empire are not so important, nor are their duties so varied, as in the Hanseatic towns. The oldest ones were established by Napoleon in 1802 in Cologne, Crefeld, Aachen, Stolberg and other towns which were then under the control of France, and they were submitted to the legislation which regulated the chambers organized in France at the same time. The model set up by the French was more or less closely followed in the subsequent establishment of institutions of this nature in other German states. The Berlin chamber was only constituted on the 1st of April 1902. A trade corporation called the "Aelteste der Kaufmannschaft" previously fulfilled, to a certain extent, the duties of a chamber of commerce. The new chamber rests on a broader basis than the old corporation, which, however, remains intact, though the sphere of its action has been restricted.

Broadly speaking, the German chambers are elected by the registered tradespeople and the merchants. Throughout the whole of Germany chambers are under the strict supervision of the state minister of commerce, and cannot be established except with his permission. He fixes the number of members as well as the amount of the state allocation to the chamber. In Prussia and Bavaria the government is entitled to dissolve chambers whenever it considers it advisable to do so, and there is always a government commissioner in attendance at all meetings. In most cases the local government allows a fixed sum for the expenses of chambers of commerce, and if this amount is exceeded the electors who are on the commercial register have to make good the excess by the striking of a special rate. In some states, *e.g.* Brunswick, Württemberg and Baden, the electors cannot be called upon to pay for deficiencies more than an amount fixed by law. In Bavaria chambers get a subvention from the district and central funds.

The duties and powers of the German chambers are practically the same as those of the French chambers.

The German government did not, like the French, interfere with the liberty of association of chambers of commerce, and as a result German chambers have united, together with other trade corporations, in an association called the "Deutsche Handelstag," founded in 1861, and carried on in its present form since 1886.

German Chambers Abroad and Foreign Chambers in Germany.

The German government is understood to be opposed to the formation of German chambers of commerce abroad, and as a matter of fact there are no German chambers in Europe outside of Germany. A few have been established in South America, but they are purely voluntary associations. No foreign chambers of commerce exist in Germany.

b. Semi-Official Corporations.—Besides the chambers of commerce, there exist, chiefly in Prussia, various old-established and quasi-official corporations, whose views receive as careful consideration from the government as do those of chambers of commerce. The Berliner Aelteste der Kaufmannschaft is one of the most important of these corporations, but the Gewerbekammer of Memel, the Kaufmännische Verein of Breslau, the Vorsteher Amt der Kaufmannschaft of Koenigsberg also deserve mention. Others exist in Elbing, Stettin, Danzig, Tilsit and Magdeburg. They originated for the most part in ancient gilds or associations of commercial firms, and were organized in their present form between 1820 and 1825.

c. Voluntary Associations.—Germany possesses also a large number of influential commercial associations of a voluntary character called the "Freie Vereine," which, especially in recent years, have greatly contributed to the commercial development of the empire.

B.—*State Departmental Organization.*

The German Empire has no ministry of commerce. As in the United States, commercial matters form only a department of the ministry of state. Most of the states of the empire have, however, their own ministries of commerce, the oldest being the Prussian ministry of commerce and industry, which dates from 1848.

Prussian Council of National Economy.

In Prussia, the minister of commerce is advised by the Volkswirthschaftsrath, or council of national economy, an official body constituted in 1880 by the Emperor William I. The functions of this council, which assembles periodically under the presidency of the minister of commerce, are also similar to those fulfilled in France by the Conseil Supérieur du Commerce et de l'Industrie.

Commercial Museums.

The German government has taken steps to facilitate the dissemination of commercial intelligence by the establishment of commercial museums, which are variously called "Handelsmuseen," "Ausfuhrmusterlager" or "Exportmusterlager." The first of these, which are on the model of the Vienna Handelsmuseum, was opened in Berlin in 1883. Others followed in Munich, Karlsruhe, Frankfort, Cologne, Dresden, Leipzig, Weimar, &c. They perform, to a certain extent, much the same functions as those performed in England by the commercial intelligence branch of the board of trade.

Consular Service.

A perusal of the instructions given to German consuls with regard to commercial matters shows that the German consular body is in this respect very much in the same position as the British consular body. If German consuls as a whole have been especially active and successful in promoting German commercial interests, it is not on account of the nature of the instructions received from their government, these instructions being to all intents and purposes similar to those issued to British consuls, but because particular care was taken to select consuls from a class of men imbued with the desire of increasing the greatness of their country by the promotion of German trade.

Agricultural Attachés.

Of distinctly commercial attachés, like those of Great Britain and Russia, Germany has none; but in addition to the consular body she is represented in foreign countries by five attachés or experts, whose duties are to study the movements of agricultural produce, and interest themselves in agricultural matters generally. They cover Great Britain, France, Russia, the Danube district and the United States.

V.—Belgium

A.—*Commercial Associations.*

The important place which Belgium has taken in international trade has directed much attention to her commercial organization, which comes nearer to the British model than that of any other European country. Belgian chambers of commerce were on the French system until 1875, when all official ties between them and the government were broken, and full liberty was given to commercial associations to establish and govern themselves in their own way. The Belgian chambers have now no administrative functions of any kind, but the Belgian government never fails to consult them in matters likely to interest the commercial community. The most important chambers are those of Antwerp, Brussels, Ghent, Liége, Charleroi, Verviers and Namur. Mention should also be made of the federations of industrial and commercial associations at Antwerp and at Brussels, and of the syndical union of Brussels. In some places there are Liberal and Conservative chambers of commerce.

In addition to institutions representative of the general interests of commerce and industry, the principal trades have also in the larger cities separate associations or syndicates. There are a large number of associations for the promotion of colonial trade, which have grown up since the establishment of the Congo Free State. A number of Belgian chambers of commerce also exist abroad, the first of which was established in New York in 1867.

B.—*State Departmental Organization.*

The Belgian ministry of commerce, under whose control commercial matters are placed, dates only from 1895, previous to which time the department of commerce at the ministry for foreign affairs fulfilled the same functions. The ministry has established in Brussels a Commercial Museum, similar to those of Germany and Austria, to centralize commercial intelligence and facilitate its dissemination.

VI.—Other Countries

Austria-Hungary.—The control exercised by the government over commercial organizations in Austria and in Hungary is very close. The only institutions of this kind of any importance within the dual monarchy are the chambers of commerce. They are official bodies, regulated by the law of the 29th of June 1868, which is, as regards the functions of chambers, almost similar to the French law. But the Austrian chambers, in certain cases, have the right to elect members of parliament, which right depends upon taxation. Within the Trieste district one-third of the members of chambers of commerce may be foreigners.

Austria and Hungary have each a ministry of commerce, the former since 1853 and the latter since 1867, whose jurisdiction is strictly confined to internal trade matters in each country. Whenever important questions arise affecting common interests the Gemeinsame Zoll-Conferenz, or Common Customs Conference, is summoned. This conference is made up of representatives of the various ministries of both countries. Matters arising out of commercial relations with foreign countries are under the control of the commercial department of the imperial foreign office.

The Vienna commercial museum was the prototype of similar institutions. It was established in 1875, as a consequence of the Vienna International Exhibition of 1873, and was followed shortly afterwards by the establishment of a similar one in Budapest.

Italy.—The chambers of commerce and arts, which are regulated by the law of 1862, are official bodies. They are instituted, and may be dissolved, by royal decree, and their functions are almost similar to those performed by the French chambers. They are, however, at liberty to unite for the consideration of commercial and industrial questions of common interest, and are entitled to own property and to levy taxes for their maintenance.

An advisory council is attached to the ministry of commerce, which dates from 1878. This council is called upon to give an opinion with reference to all matters connected with trade and industry. There are also two commercial museums, one in Rome and one in Milan.

Spain.—Spanish chambers of commerce were organized by a royal decree of 1886, which places them under the control of the Ministro de Fomento. They are self-supporting bodies with unlimited membership, but have also an official standing. In order to belong to them one must be of Spanish nationality, be engaged in trade, have paid direct taxes to the state for at least five years for the business in connexion with which membership of the chamber is sought, and pay annually the amount of the subscription provided by the regulations. The government must consult chambers of commerce upon treaties of commerce and navigation, tariff changes, the creation of commercial exchanges and the organization of commercial education. Owing to the peculiarity of their constitution the Spanish chambers are much more representative of the feelings of the commercial community, and much less under the strict control of the government, than similar institutions in other continental countries. Spain has no ministry of commerce proper, the duties of this office being performed by the commercial sub-department of the Ministro de Fomento, which dates from 1847.

Portugal.—In Portugal the organizations corresponding to chambers of commerce, which are called "commercial associations," are voluntary associations kept up by the subscriptions of their members. The associations at Lisbon and Oporto are the only ones of importance.

Russia.—Attached to the department of trade and manufactures of the ministry of Finance, which in Russia does duty for the ministry of commerce, there is an official council of trade and manufactures which sits in St Petersburg, and is presided over by a representative of the ministry. A similar council is also in existence at Moscow. In addition to these there are six local bodies, called the "local committees of trade and manufactures," entrusted with the care of commercial interests in Archangel, Odessa, Rostov-on-the-Don, Tver, Tikhvin and Ivanovo-Voznesensk. At Warsaw there is a "committee of manufactures." The committees are purely consultative bodies.

Closer to what we know as chambers of commerce are the institutions called "exchange committees." They are voluntary associations, chosen by a council elected for the purpose by the commercial community; they generally consist of twelve members elected for five years, and the president is appointed by the minister of finance. Two important commercial societies, although unofficial, are recognized and frequently consulted by the government, viz. the Society for the Encouragement of Russian Trade and Industry, of St Petersburg, and the Society for the Encouragement of Navigation, of Moscow.

The Russian government is represented abroad by commercial attachés, who are known as "agents of the Russian ministry of finance." The duties of these attachés are almost similar to those of the British commercial attachés, but they are entrusted with the promotion of Russian financial as well as commercial interests.

Japan.—Commercial matters in Japan come within the cognizance of the minister of state for agriculture and commerce. The chief commercial associations are the chambers of commerce, which are under the direct control of the minister. They are official bodies, with a constitution somewhat resembling that of the French chambers. The members must be Japanese subjects.

Authorities.—Correspondence respecting diplomatic and consular assistance to British trade abroad. *Parliamentary Papers*, No. 16, 1886, and No. 5, 1897; *Report of the Departmental Committee on the Dissemination of Commercial Intelligence* (2 vols., c. 8962, 8963, 1898); Reports on the constitution and functions of ministries of commerce and analogous branches of foreign administrations. *Parliamentary Paper*, No. 12 (1889). Reports, rules, by-laws and articles of association of the various chambers mentioned. W. H. Schoff, *American Commercial Institutions* (New York, 1900); *Foreign Trade Policies*; American Consular Report, No. 307 (Dec. 24, 1898). *The Bureau of American Republics Annual Reports* (Washington). *The Chambers of Commerce Year Book* (York, 1909).

TRADE UNIONS, combinations for regulating the relations between workmen and masters, workmen and workmen, or masters and masters, or for imposing restrictive conditions on the conduct of any industry or business.

I.—The United Kingdom

History of British Legislation.

By the English common law such combinations were, with certain unimportant exceptions, regarded as illegal. They were considered to be contrary to public policy, and were treated as conspiracies in restraint of trade. Those who were concerned in them were liable to be criminally prosecuted by indictment or information, and to be punished on conviction by fine and imprisonment. The offence was the same whether it was committed by masters or by workmen. But although the common law applied *mutatis mutandis* to both of them alike, it was, practically speaking, in reference rather to the latter than to the former that its effects were developed and ascertained. Although workmen, as individuals, might lawfully consent or refuse to labour for any remuneration or for any time they pleased, the hostility of the common law to combinations effected the result that when two or more of them joined together, and agreed to labour only on certain stipulated terms, their agreements were not only null and void, but were criminal offences subject to punishment. It was immaterial whether the end they had in view was to determine wages or to limit work; or whether the means they adopted for promoting its attainment was a simultaneous withdrawal from employment, an endeavour to prevent other workmen from resuming or taking employment, or an attempt to control the masters in the management of their trade, the engagement of journeymen or apprentices, or the use of machinery or industrial processes; or whether in seeking to enforce their demands they relied merely on advice and solicitation, or resorted to reproach and menace, or proceeded to actual violence. In any event their combination in itself constituted a criminal conspiracy, and rendered them amenable to prosecution and punishment.

From the reign of Edward I. to the reign of George IV. the operation of the common law was enforced and enlarged by between thirty and forty acts of parliament, all of which were more or less explicitly designed to prohibit and prevent the organization of labour. But the rise of the manufacturing system towards the end of the 18th century, and the revolution which accompanied it in the industrial arrangements of the country, were attended by a vast and unexpected extension of the movement which the legislature had for so long essayed to suppress. Among the multitudes of workmen who then began to be employed in factories, trade unions in the form of secret societies speedily became numerous and active, and to meet the situation a more summary procedure than that which had hitherto been available was provided by an act passed in 1800.

Act of 1800.

By this statute it was enacted that all persons combining with others to advance their wages or decrease the quantity of their work, or in any way to affect or control those who carried on any manufacture or trade in the conduct and management thereof, might be convicted before one justice of the peace, and might be committed to the common gaol for any time not exceeding three calendar months, or be kept to hard labour in the house of correction for a term of two calendar months.

The discontent and disorder consequent upon the introduction of steam and improved appliances into British manufactures in the first quarter of the 19th century, in conjunction with a state of commercial depression and national distress, led to the nomination of a select committee by the House of Commons, to inquire into the whole question of what were comprehensively designated the "combination laws," in the session of 1824. The committee reported to the House that "those laws had not only not been efficient to prevent combinations either of masters or workmen, but on the contrary had, in the opinion of many of both parties, had a tendency to produce mutual irritation and distrust and to give a violent character to the combinations, and to render them highly dangerous to the peace of the community." They further reported that in their judgment "masters and workmen should be freed from such restrictions as regards the rate of wages and the hours of working, and be left at perfect liberty to make such agreements as they mutually think proper." They therefore recommended that "the statute laws which interfered in these particulars between masters and workmen should be repealed," and also that "the common law under which a peaceable meeting of masters or workmen might be prosecuted should be altered." In pursuance of their report, an act, 5 Geo. IV. c. 95, was at once brought in and passed. But the immediate results of the change which it effected were regarded as so inconvenient, formidable and alarming, that in the session of 1825 the House of Commons appointed another select committee to re-examine the various problems, and review and reconsider the evidence submitted to their predecessors. They reported without delay in favour of the total repeal of the act of 1824, and the restoration of those provisions of the combination laws, whether statutory or customary, which it had been more particularly intended to abrogate. The consequence was an act passed in 1825 of which the preamble declares that the act of 1824 had not been found effectual, and that combinations such as it had legalized were "injurious to trade and commerce, dangerous to the tranquillity of the country, and especially prejudicial to the interests of all who were concerned in them." The effect of this act was to leave the common law of conspiracy in full force against all combinations in restraint of trade, except such as it expressly exempted from its operation, as it had been before the act of 1824 was passed. It comprised, however, within itself the whole of the statute law relating to the subject, and under it no persons were liable to punishment for meeting together for the sole purpose of consulting upon and determining the rate of wages or prices which they, being present, would require for their work or pay to their workmen, or the hours for which they would work or require work in any trade or business, or for entering into any agreement, verbal or written, for the purpose of fixing the rate of wages or prices which the parties to it should so receive or pay. But all persons were subjected to a maximum punishment of three months' imprisonment with hard labour who should by violence, threats or intimidation, molestation, or obstruction, do, or endeavour to do, or aid, abet or assist in doing or endeavouring to do, any of a series of things inconsistent with freedom of contract which the act enumerated and defined.

Act of 1824. *Act of 1825.*

In 1859, in order to remove certain doubts which had arisen as to the true import and meaning of the undefined words "molestation" and "obstruction," it was provided by an amending act that "no person, by reason merely of his endeavouring peaceably and in a reasonable manner, and without threat or intimidation, direct or indirect, to persuade others to cease or abstain from work, in order to obtain the rate of wages or the altered hours of labour agreed to by him and others, should be deemed to have been guilty of 'molestation' or 'obstruction.'"

Act of 1859.

In spite of the partial recognition which trade unions had thus received, they continued to be unlawful, although not necessarily criminal, associations. In certain cases, they were by statute exempted from penal consequences, and their members were empowered to combine for specified purposes, and to collect funds by voluntary contributions for carrying them into effect. But in the estimation of the common law the special privileges which had been accorded to them under particular circumstances did not confer any general character of legality upon them, and where their rules were held to be in restraint of trade, as in the prohibition of piece-work or the limitation of the number of apprentices, they were still regarded as conspiracies. In this condition the law was when what became notorious as the "Sheffield and Manchester outrages" suggested the appointment of the royal commission on trade unions, which investigated the subject from 1867 to 1869. The outcome was, first, a temporary measure for the more effectual protection of the funds of trade unions, passed in 1869, and, secondly, the two measures which, as amended and amending, are cited together as the "Trade Union Acts 1871 and 1876."

Acts of 1869-1876.

Under these statutes, construed with the Conspiracy and Protection of Property Act 1875, the law relating to combinations, whether of workmen or of masters, entered upon a new phase. In connexion with trade disputes no person can be prosecuted for conspiracy to commit an act which would not be criminal if committed by him singly. The purposes of a trade union are not to be deemed illegal merely because they are in restraint of trade, and the circumstance that they are in restraint of trade is not to render any member of it liable to prosecution, nor is it to avoid or make voidable any agreement or trust relating to it. No court, however, can entertain legal proceedings with the object of directly enforcing or recovering damages for the breach of an agreement between the members of a trade union as such, concerning the conditions on which the members for the time being shall or shall not sell their goods, transact their business, employ or be employed, or the payment by any person of any subscription or penalty to a trade union, or for the application of the funds of a trade union to provide benefits or to furnish contributions to any employer or workman not a member of such trade union in consideration of such employer or workman acting in conformity with the rules or resolutions of such trade union, or to discharge any fine imposed upon any person by any court of justice or any agreement made between one trade union and another, or any bond to secure such agreement. But such incapacity to sue on such agreements is not to be taken as constituting any of them illegal. Every person, however, commits a misdemeanour, and on

General Effects.

conviction is liable to a maximum fine of £20, or to a maximum imprisonment of three months with hard labour, who wilfully and maliciously breaks a contract of service or hiring, knowing or having reasonable cause to believe that the probable consequence of his so doing, either alone or in combination with others, will be to endanger human life or cause serious bodily injury, or to expose valuable property, whether real or personal, to destruction or serious injury; or, who, being employed by a municipal authority or by any company or contractor on whom is imposed by act of parliament, or who have otherwise assumed, the duty of supplying any place with gas or water, wilfully and maliciously breaks a contract of service or hiring, knowing, or having reasonable cause to believe, that the probable consequence of his so doing, alone or in combination with others, will be to deprive the inhabitants of that place, wholly or in part, of their supply of gas or water; or who, with a view to compel any other person to do or to abstain from doing any act which such other person has a right to abstain from doing or to do, wrongfully and without legal authority uses violence to or intimidates such other person or his wife or children, or injures his property, or who persistently follows such person about from place to place, or who hides any tools, clothes or other property owned or used by such other person, or deprives him of or hinders him in the use thereof, or who watches or besets the house or other place where such person resides or works or carries on business or happens to be, or the approach to such house or place, or who follows such other person with two or more other persons in a disorderly manner in or through any street or road. Attending at or near the house or place where a person resides or works or carries on business, in order merely to obtain or communicate information was not watching or besetting within the statute, but this proviso has since been repealed. In regard to registration, trade unions are placed on a similar footing with friendly and provident and industrial societies, and they enjoy all the privileges, advantages and facilities which those associations possess and command, except in so far as they differ by the fact that there is no legally enforceable contract between a trade union and its members, and that the right of a registered trade union to invest funds with the National Debt Commissioners is limited, and in a few other matters. On their side, however, they have to comply with the same conditions, are subject to the same liabilities, and are compelled to make the same periodical returns.

Later Legislation.

During the years following 1876 several important amendments of the law, other than special trade union legislation, and the decisions of the courts in various cases, led up to the important act of 1906. These affected principally the liability of trade union funds to be taken in execution for the wrongful acts of agents of the union, the statute law relating to picketing and other incidents of strikes, and the law of conspiracy as affecting trade unions.

The two latter points are dealt with in the article on Strikes and Lock-Outs, and it may suffice here to say that the clauses in the act of 1875 prescribing punishment for watching and besetting a house, &c., with the view of compelling any other person in the manner set forth, have been amended by the repeal of the proviso that "Attending at or near the house or place where a person resides, or works, or carries on business, or happens to be, or the approach to such house or place, in order merely to obtain or communicate information, shall not be deemed a watching or besetting within the meaning of this section" by the enactment in the act of 1906 that: "It shall be lawful for one or more persons, acting on their own behalf or on behalf of a trade union or of an individual employer or firm in contemplation or furtherance of a trade dispute, to attend at or near a house or place where a person resides or works or carries on business or happens to be, if they so attend merely for the purpose of peacefully obtaining or communicating information, or of peacefully persuading any person to work or abstain from working."

The object was to include the right of peaceful persuasion which had been supposed by parliament to be implied in the terms of the act of 1875. Further, the law of conspiracy has been amended by enactments in the act of 1906 that: "An act done in pursuance of an agreement or combination by two or more persons shall, if done in contemplation or furtherance of a trade dispute, not be actionable unless the act if done without any such agreement or combination would be actionable," and "An act done by a person in contemplation or furtherance of a trade dispute shall not be actionable on the ground only that it induces some other person to break a contract of employment or that it is an interference with the trade, business or employment of some other person, or with the right of some other person to dispose of his capital or his labour as he wills."

Leading Cases in the Law-courts.

The act of 1875, in the words of Lord Cairns, was framed on the principle that "the offences in relation to trade disputes should be thoroughly known and understood, and that persons should not be subjected to the indirect and deluding action of the old law of conspiracy," but no one during the discussion of the bill was thinking of the civil action. This matter became important when the dicta of various judges in the House of Lords in the case of *Quinn* v. *Leathem* showed that there might be an action for damages based on any conspiracy to injure or do harm, particularly when it is considered that the very essence of a strike is in one sense injury to those against whom it is directed, and these opinions became of the utmost import to trade unions when the Taff Vale case showed that the fact of procuring to strike might also involve trade union funds in liability, even where there had been no procuring to break contracts. This important decision arose through the amendment of general procedure under the Judicature Acts in 1881. The distinction was abolished between legal and equitable rules as regards parties to sue and be sued, and in 1883 there was issued a General Order No. xvi. of the supreme court, rule 9 of which prescribed that where there are numerous parties having the same interest in one cause or matter, one or more of such persons may sue or be sued, or may be authorized by a court or judge to defend in such cause or matter, on behalf or for the benefit of all persons so interested. It was decided in *Temperton* v. *Russell* in 1893 where three trade unions were made defendants to represent all the members, and the order did not apply in the case of a trade union, because the words of the order "numerous parties having the same interest in one cause or matter" could only be satisfied by parties who had, or claimed to have, a beneficial proprietary right which they were asserting or defending, from which it was inferred that they could not be sued at all, and in the report of the Royal Commission on Labour in 1894 the opinion was either assumed or expressly stated that they could not be sued in tort. In 1901 the House of Lords overruled *Temperton* v. *Russell* in the case of the *Duke of Bedford* v. *Ellis*, holding that the General Order No. xvi. rule 9, was universal in its application. In the same year the Taff Vale case came before the House of Lords. In the first place, expounding the Trade Union Act 1871, they held unanimously that from the provisions in that act concerning registered trade unions there is to be legally inferred an intention of parliament that a trade union might be sued in tort in its registered name, with the consequence that trade union funds would be liable for any damages that might be awarded. Secondly

Taff Vale Case.

—apart from the Trade Union Act—Lord Macnaghten and Lord Lindley expressed an unhesitating opinion that under the General Order No. xvi. as interpreted in *Duke of Bedford* v. *Ellis*, any trade union, whether registered or not, could be sued in tort by means of a representative action. Trade unionists protested against the result as a decision of judges making a practically new law against trade unions and nullifying the settlement of their status made by the legislature in 1871, and in June 1903 a royal commission was again appointed to inquire into the subject of trade disputes and trade combinations and as to the law affecting them, and to report on the law applicable to the same and the effect of any modifications thereof.

The majority of the commission reported in January 1906 in favour of an alteration in the law relating to picketing and conspiracy, but against any alteration of the law as laid down in the Taff Vale judgment. A different view was, however, expressed in the Trade Disputes Act passed in the same year, whereby it was enacted with reference to trades union funds that "an action against a trade union, whether of workmen or masters, or against any members or officials thereof on behalf of themselves and all other members of the trade union in respect of any tortious act alleged to have been committed by or on behalf of the trade union, shall not be entertained by any court," although "nothing in this section shall affect the liability of the trustees of a trade union to be sued in the events provided for by the Trades Union Act 1871, section 9, except in respect of any tortious act committed by or on behalf of the union in contemplation or in furtherance of a trade dispute." This act and the two previous acts are cited together as the Trade Union Acts 1871 to 1906, and form the present statutory enactments upon the subject.

Act of 1906.

In December 1909 one of the most important judgments in connexion with trade unions was delivered in the case of *Osborne* v. *Amalgamated Society of Railway Servants*. The litigation had extended over two years, ending in the House of Lords (December 21, 1909) upholding the decision of the court of appeal (L.R. 1909, ch. 163). The plaintiff, who had been a member of the Amalgamated Society of Railway Servants since 1892, sued his trade union to have it declared that one of its current rules, which provided, amongst other things, for parliamentary representation and the enforced levy of contributions from him and other members of the society, towards the payment of salaries or maintenance allowance to members of parliament pledged to observe and fulfil the conditions imposed by the Labour Party, was *ultra vires* and void. It was decided in the King's Bench against the plaintiff, but the judgment was reversed by the court of appeal, whose decision was upheld by the House of Lords. This meant that the Labour Party in the House of Commons would have to find other ways and means than contributions from trade unionists to maintain their members in parliament. A voluntary levy was attempted, but did not meet with any success, and in 1910 agitation was set on foot by the Labour Party for the reversal of the "Osborne judgment." They also announced in September their intention of making a change in the constitution of their party by eliminating the necessity of each member signing an acceptance of certain conditions, on the ground that the party had arrived at a state when it could trust to ordinary party loyalty to keep their members' action in accordance with the policy of the party. It was also hoped that it would meet many objections raised against their agitation for the reversal of the Osborne judgment. The agitation had the result of increasing the force of the movement for payment of members, not only in the Liberal party but also among the more progressive Conservatives.

The Osborne Judgment.

Trade unions, in the sense in which the term is now understood, appear to be almost exclusively of modern growth. Though combinations among various classes of workmen to improve their position have doubtless been formed from time to time from an early period, such combinations, up to comparatively recent years, were mostly ephemeral, almost the only class among whom permanent associations of journeymen are known to have existed in the middle ages being the masons, whose confederacies were prohibited by law in 1425. With this doubtful exception, there is little or no trace of permanent combinations corresponding to the modern trade union before the 18th century. During the period when wages and conditions of employment were the subject of State regulation (*e.g.* under the Statute of Apprentices of Elizabeth), combinations to exact higher rates or other conditions than those so fixed were naturally regarded as illegal conspiracies.

History of Organization.

The craft gilds of the middle ages have sometimes been regarded as the true predecessors of trade unions, but the analogy must not be pressed too far. The structure, constitution and functions of a gild of craftsmen, aiming at the protection and regulation of the craft as a whole, were essentially different from those of a trade union, formed to protect one class of persons engaged in an industry against another. Nor is there any trace of direct continuity between gilds and trade unions, for the claim of certain Irish trade unions to be descended from gilds will not bear scrutiny (see Webb, *History of Trade Unionism*, appendix). The only true sense in which it can be said that there is a certain indirect historical filiation between gilds and trade unions is that, as pointed out by Brentano, some of the earliest trade unions had for their original object the enforcement of the decaying Elizabethan legislation, which in its turn had taken the place of the obsolete regulation of industry by the craft gilds, so that among the rules and objects of such unions would naturally be some bearing a likeness to gild regulations.

The actual way in which trade unions first came into being probably varied very greatly. In some cases, as stated above, their origin can be definitely traced to associations for enforcing the legal regulation of industry against the opposition of employers; in others, the meetings of journeymen belonging to the same trade for such purposes as sick or burial clubs became naturally the nucleus of secret combinations to raise wages. The growth of the "capitalistic" system of industry, under which the workman no longer owned the materials or instruments with which he worked, was one of the most potent causes of the development of workmen's combinations. The efforts of trade unions to revive the enforcement of the Elizabethan legislation not only failed, but led to its repeal (1813–1814); but the laws against combinations, which had been made more stringent and more general by the acts of 1799–1800, remained unaltered until 1824. In spite of these acts, which made all combinations illegal, there is evidence that trade clubs of journeymen existed and were tolerated in many trades and districts during the first quarter of the 19th century, though they were always subject to the fear of prosecution if they took hostile action against employers; and in many cases strikes were suppressed by the conviction of their leaders under these acts or under the common law of conspiracy. The partial protection accorded to societies for the purpose of regulating wages and hours of labour by the law of 1825 led to a rapid multiplication and expansion of trade unions, and to an outburst of strikes, in which, however, partly owing to the widespread commercial depression, the workmen were mostly unsuccessful. Thus the first impetus given to trade unions by the modification of the combination laws was followed by a collapse, which in its turn was followed (in the third decade of the century) by a succession of attempts on the part of workmen to establish a federal or universal combination, to embrace members not of one but of several trades. To this new form of combination, which excited a good deal of alarm among employers, the term "trades union," as distinct from trade union, was applied. All these general movements, however, proved short-lived, and the most extensive of them, the "Grand National Consolidated Trades Union," which was formed in 1834 and claimed half a million adherents, only had an active existence for a few months, its break-up being hastened by the conviction and transportation of six Dorchester labourers for the administration of unlawful oaths. In the years of depressed trade which followed, trade unionism once more declined, and the interest of workmen was largely diverted from trade combinations to more general political movements, *e.g.* Chartism, the Anti-Corn-Law agitation and Robert Owen's schemes of co-operation.

From 1845 we trace another revival of trade unions, the characteristic tendency of this period being the amalgamation of local trade clubs to form societies, national in scope, but confined to single or kindred trades. High rates of contribution, and the provision of friendly as well as trade benefits, were among the features of the new type of union, of which the Amalgamated Society of Engineers, formed in 1851, was the most important example. The growth of unions of the new type was followed by a development of employers' associations in the 'sixties, and by a number of widespread strikes and lock-outs, and also by various efforts to promote arbitration and conciliation by the establishment of joint boards of employers and employed. (See ARBITRATION AND CONCILIATION and STRIKES AND LOCK-OUTS.)

A series of outrages at Sheffield and Manchester in 1865–1866, in which officials of some local trade societies were implicated, led to the appointment in 1867 of a Royal Commission on Trade Unions, whose report was followed by the passage of the Trade Union Act of 1871, which as amended in 1876 and 1906 now governs the legal position of trade unions. Conferences of trade union representatives held in 1866 and 1867 to determine their policy with respect to the royal commission of inquiry, led to the gatherings of the trade union congress which are still held annually.

The period of inflated trade which began in 1871 caused, as usual, another rapid growth of trade combinations, of which the most characteristic feature was their extension to agricultural and general labourers. To meet this new development of combination, the National Federation of Associated Employers of Labour was formed in 1873. The years of depression, 1875–1880, were marked by a series of unsuccessful strikes against reductions of wages, and by a general decline of trade unions, which did not again revive until nearly ten years later, when the new wave of prosperous trade brought with it an outburst of strikes, chiefly among unskilled labourers, for improved conditions, of which the most notable was the strike of the London dock labourers in 1889. These trade movements were accompanied by the formation of a large number of unions of a type more akin to those of 1830–1834 than to the more modern trade-friendly society with its high contributions and benefits. The "new unions" were chiefly among unskilled labourers; their rates of contributions were from 1d. to 3d. a week, and as a rule they only offered strike benefit. Another characteristic was the extent to which their leaders were permeated with the Socialistic doctrines which had then recently taken root in Great Britain, and which led them to advocate positive state interference with industry in the interests of the labourers (*e.g.* the legal limitation of hours of labour).

The reports of the Royal Commission on Labour, which sat from 1891 to 1894, contain much valuable information on the state of facts and on the opinions of employers and workmen at this period.

From 1892 onwards the progress of trade unionism can be traced statistically. The depression of trade, 1892–1895, brought with it, as usual, some decline in trade unionism; but though many of the "new unions" collapsed, some of the more important have survived to the present time. The revival of trade which began in 1896 was naturally accompanied by an increase in the strength of trade unions; but the most marked characteristic of this period was the extension and consolidation of employers' associations, of which perhaps the most notable is the Engineering Employers' Federation, which was originally formed on the Clyde, but gradually extended to other districts and became a national organization of great strength during its successful struggle with the Amalgamated Society of Engineers in 1897–1898. Among the other more important employers' associations and federations of a national character may be mentioned the Shipping Federation, the Federated Coal Owners, the Ship-building Federation, the Federation of Master Cotton-Spinners' Associations, the National Federation of Building Trade Employers, and the Incorporated Federated Associations of Boot and Shoe Manufacturers.

In 1899 a general federation of trade unions was established which had in 1907 a membership of 650,000 in 117 affiliated societies. This federation links the trade unions of the United Kingdom with those of other countries by its affiliation with the international federation of trade unions, which embraces the national federations of the principal European countries. During recent years there has been a noticeable tendency towards the creation of federations of trade unions, and the absorption of the smaller by the larger societies. Trade unions, both in their historical development and their present organization, present a very great variety of constitutions.

Constitution.

The oldest type is that of the local trade club, consisting of a comparatively small number of men following the same occupation in the same locality. A large number of unions have never progressed beyond this primitive form of organization. The government is of the simplest kind, by a general assembly of all the members, while such officers as are required to carry on the necessary routine business of the society are chosen by rotation or even by lot.

Indisposition to concentrate power in the hands of permanent officers and a tendency to divide the business of management equally among all the members, instead of delegating authority to a few chosen representatives, are leading characteristics of trade unions in this primitive form. The organization here described, even if adequate for ordinary current requirements, is ill suited for conducting a contest with employers, and accordingly in times of strife an improvised "strike committee" often comes into existence and practically governs the conduct of the dispute. No doubt this double constitution of the old trade club as a loosely organized friendly society, converting itself at times into a more or less secret strike combination ruled by an irresponsible committee, is to be traced to the time when trade unions as such were illegal combinations and had to carry out their objects under the guise of friendly societies. The Friendly Society of Ironfounders (established in 1809), though it has to a great extent outgrown its primitive constitution, retains in its name the mark of its origin, while the government of the London Society of Bookbinders, by mass meeting of its members, offers an example of the persistence of traditional methods under wholly changed conditions. The Sheffield trade clubs, responsible for the outrages which led to the appointment of the Trade Union Commission in 1867, and subsequently to the passage of the Trade Union Acts, conformed as a rule to the primitive type. At the present time over 750 trade unions are known to exist which are purely local in character, with no branches. The next step in trade union evolution seems to have generally been an alliance or federation of two or more local clubs belonging to the same trade. This federation would make it necessary to provide some machinery for common management, the simplest and crudest expedient being for each of the allied clubs to act in rotation as the governing branch. Thus the government of the federation or "amalgamated society" was at any given time confided to the members of a single locality, and the seat of government was periodically shifted. Some federal societies (*e.g.* the Mutual Association of Journeymen Coopers) still retain this primitive form of government.

As the tendency developed for local clubs to unite, the necessity of permanent officials to cope with the growing business of the amalgamation caused the institution of a paid secretary (usually elected by the whole body of members), and this led naturally to the fixing of the seat of administration at a particular centre instead of rotating among the branches. Some continuity of policy and of office tradition was thus made possible, but the executive committee almost invariably continued to consist of the local committee of the district where the seat of government happened to be. Thus up to 1892 the business of the Amalgamated Society of Engineers, a society with hundreds of branches all over the United Kingdom and even abroad, was conducted by a committee elected by the London branches. The Boilermakers continued a somewhat similar form of government up to 1895; and many great societies, *e.g.* the Amalgamated Society of

Carpenters and Joiners, continue a somewhat similar system to the present day.

The plan of entrusting the government of a national society to a local executive has obvious conveniences, where the society consists of a body of working men scattered over a large area and with no leisure for travelling. But the control exercised by a locally-elected committee over a general secretary deriving his authority not from them but from the vote of a much wider constituency, could hardly be expected to be very effective; while the expedients of referring all important questions to a vote of the whole body of members, and of summoning at periodical intervals special delegate meetings to revise the rules, have proved in practice but clumsy substitutes for the permanent control and direction of the executive officers by a representative council. Quite as ineffective in some cases has been the authority of a mere local executive over the committees of other districts. Accordingly, some of the largest "amalgamated" unions have now adopted a representative system of government. Thus in 1892 the Engineers revised their rules so as to provide for the election of the executive council by vote of all the members divided into eight equal electoral districts. The members of council so elected are permanent paid officials, devoting all their time to the work of the society. The general secretary, however, continues to be chosen by the whole body of members, while the responsibility of the council is also weakened by the institution of "district delegates" nominally responsible to them, but chosen by direct election in the various districts. (This division of authority and consequent weakness of responsibility was one of the causes of the state of things which led to the great engineering dispute of 1897, and it also led to a deadlock in negotiations on the north-east coast in 1908, the executive being powerless to enforce its views.) The Boilermakers adopted the system of a permanent executive in 1895.

In the case of certain highly-localized industries, such as cotton and coal, the conditions have admitted of a somewhat different form of constitution from that described above. Thus the Amalgamated Association of Operative Cotton-Spinners is a federal organization, consisting of a number of local associations, all, however, situated within a comparatively small area. The governing bodies of the association are—(1) a quarterly meeting of about a hundred representatives of the districts; (2) an executive committee of thirteen chosen by the above representative meeting, of whom seven must be working spinners and the other six are usually permanent district officials; (3) a sub-council to transact the ordinary daily work of the association, consisting of the six official members referred to above. The secretary is chosen by the representative meeting, and engages his own office assistants. Here we have the familiar features of representative institutions—a large legislative body, a small executive chosen by and responsible to this body, and a still smaller group of permanent officials to transact ordinary business.

Lastly, there are some large societies constituted not by the aggregation of local clubs or the federation of neighbouring associations, but originally founded as "national societies" divided into districts and branches for administrative convenience. An example is the Amalgamated Society of Railway Servants, founded in 1872.

Besides the tendency of the national society with branches to swallow up the local trade club, there is a further tendency among the larger societies to form federations for certain common purposes. Such federations are to be distinguished from national trade unions, inasmuch as their members are societies and not individuals, and as a rule their powers over their constituent organizations are limited to certain specific objects. On the other hand, they are more than merely consultative bodies (such as local trades councils).

Some federations consist of unions in the same industry in different districts (*e.g.* the Miners' Federation). "Single trade" federations like this have usually considerable powers, including that of imposing levies.

In the cotton-spinning trade, the trade union organization has a federal character, and the Amalgamated Association of Operative Cotton-Spinners, in spite of its name, is, strictly speaking, a federation.

Other federations (*e.g.* in the building trade) are formed of allied trades in the same locality, and usually have little executive power. The Federation of Engineering and Shipbuilding Trades has among its objects the settlement of disputes between members of its constituent societies as to the limits of their work. Some federations aim at embracing societies in all kinds of industries, but as a rule such organizations have not proved long-lived. The most recent example is the "General Federation of Trade Unions," formed in 1899, referred to above.

Since 1866 a congress of delegates from trade unions has met annually for discussion, and a parliamentary committee elected by this congress watches over matters in which trade unions are interested during the ensuing year.

Objects and Methods.

The principal object of every trade union is to protect the trade interests of its members, and to strengthen their position in bargaining with their employers with regard to the conditions under which they work. The chief means by which they seek to attain these objects (apart from political methods such as the promotion of legislation or of administrative action by public authorities) are twofold: viz. the support of members when engaged in a collective dispute with employers by the payment of "dispute" benefit, and the insurance of members against loss from want of work by the payment of "unemployed" benefit, so as to enable them to refuse any terms of employment inferior to those recognized by the trade union. All trade unions in one form or another provide "dispute" benefit, but a separate "unemployed" benefit is by no means universal, though, except in certain groups of trades, it is usual among more powerful and well established societies. Thus in the mining, clothing, and even many branches of the building trade, comparatively little is spent by trade unions on "unemployed" benefit, while, on the other hand, in the metal, engineering, shipbuilding, printing and other trades a large proportion of the total expenditure is devoted to this object (see *Statistics* below). In some important societies, such as the Amalgamated Society of Engineers, "unemployed" and "dispute" benefits are mixed up together, members engaged in a dispute receiving an addition of 5s. per week (known as "contingent" benefit) to the ordinary out-of-work pay (known as "donation").

Unemployed benefit may, of course, be regarded as a "friendly" benefit, *i.e.* a provision against one class of the casualties to which a workman is exposed—the loss of employment through slackness of trade. But in practice it also operates as a method of maintaining the "standard" rate of wages, members being entitled to it who could obtain employment, but only on conditions disapproved by the society or branch.

The conditions under which the members of a union are entitled to financial support in a strike vary in different societies, and are prescribed in the rules. Usually, though the initiative may come from the localities, the central executive must approve of the strike before it takes place, and may at any time declare it to be closed, though in some societies the central authority is often unwilling to take the responsibility of curbing its members by exercising its powers in this respect.

"Dispute" and "unemployed" benefits are the only ones which are specially characteristic of trade unions, and as regards the latter benefit, it may be said that trade unions have hitherto been the only form of organization capable of meeting the difficulties arising from "malingering." Most of the more firmly established unions, however, add to their trade functions those of friendly societies, providing sick, accident, superannuation, and funeral benefits, or some of these. The position of a trade union, however, with regard to these benefits differs very materially from that of a friendly society. The trade union is under no legally enforceable contract with its members to provide the stipulated benefits: it can change their scale, or even abolish them, by vote of its members, and a member who has contributed for years in hope of receiving them has no legal redress. Again, a member excluded from the society for some "trade" reason incidentally loses all claim to friendly benefits. The funds of a trade union applicable to trade and friendly purposes are never kept distinct (in the few cases in which some distinction is attempted, the society may "borrow" from the one fund in aid of the other in case of emergency); and a prolonged strike or depression of trade may so deplete the funds as to make it impossible for the society to meet its engagements as regards sickness or superannuation. Thus the friendly society operations of trade unions have strictly no actuarial basis, and in some cases the scale of contribution and benefit have been fixed with little regard to ultimate solvency.

On the other hand, the power of levying and varying the scale of contributions adds to some extent to the financial stability of the funds, and the provision of "friendly" as well as "trade" benefits by a trade union undoubtedly gives strength and continuity to the society, and increases its power of discipline over its members. Societies that only provide "dispute" pay are exposed to violent oscillations of membership, and also to a dangerous temptation to rush into an ill-considered strike owing to the mere accumulation of funds which can be used for no other purpose.

The statistics of trade union expenditure on benefits of various classes are given below. Of the 100 principal unions, all provide dispute benefit; 79 in the year 1905 provided unemployed benefit (including in some cases travelling pay); 79, sick or accident benefit; 37, superannuation benefit; and 87, funeral benefit; 32 unions providing all four classes of benefit.

One of the most important functions of trade unions in many industries is the negotiation of agreements with employers and employers' associations for the regulation of the conditions of employment in those industries. While undoubtedly the power of withdrawing its members from employment in the last resort adds to the power of a trade union in such negotiations, many of the most important agreements by which the conditions of labour of large bodies of workmen are governed are habitually concluded, and from time to time revised, by conferences of representatives of the trade union and employers without any strike taking place. To the functions of trade unions as fighting organizations and as friendly benefit societies should therefore be added that of providing the necessary machinery and basis for the conclusion of industrial agreements between bodies of workpeople and their employers (see ARBITRATION AND CONCILIATION, and STRIKES AND LOCK-OUTS).

While the broad objects of trade union policy are generally similar, their methods and features vary greatly in detail. Among the objects most frequently met with (besides those of raising wages and shortening hours, which may be said to be universal) are the enforcement of a "minimum" wage; the limitation of overtime; the restriction of numbers in the trade through the limitation of apprentices, or the regulation of the age of entrance; the restriction or regulation of piecework (in trades accustomed to "time" work); the preservation for members of the trade of the exclusive right to perform certain classes of work claimed by other trades (leading to so-called "demarcation" disputes); resistance to the encroachment of labourers on work considered to be "skilled" (leading to disputes as to the class of persons to be employed on machines, &c.); and the securing of a monopoly of employment for members of the union by a refusal to work with non-unionists.

Year.	Number of Unions.	Membership of Unions.[1]
1897	1292	1,622,713
1898	1261	1,659,480
1899	1255	1,820,755
1900	1244	1,928,035
1901	1238	1,939,585
1902	1203	1,925,800
1903	1187	1,903,596
1904	1153	1,864,374
1905	1136	1,887,823
1906	1161	2,106,283

[1] Includes a small number of members abroad.

Statistics.

The statistics of trade unions are very complete for recent years, but for earlier years the records are so fragmentary that it is impossible to give exact figures showing the total growth of trade unions over a long period. The table at foot of preceding column, based on the statistics published by the board of trade, shows the number and membership of all trade unions in the United Kingdom making continuous returns for each of the ten years 1897 to 1906.

The fluctuations in membership correspond in the main to the oscillations of trade, membership declining in the years of depression and increasing with the revival of trade. The decline in the number of separate unions is chiefly due to the growing tendency to amalgamate into large societies.

The following table shows the distribution of trade unions among the various groups of trades in 1905:—

Groups of Unions.	Number of Unions.	Membership in 1905. Number.	Percentage of Total.
Mining and quarrying	68	495,968	26
Metal engineering and shipbuilding	222	339,282	18
Textile	253	239,539	13
Building	101	205,383	11
Railway, dock and other transport	55	162,563	9
Public employment	48	72,182	4
Printing, bookbinding and paper	40	62,368	3
Clothing	35	60,407	3
Wood-working and furnishing	100	40,115	2
General labour	18	96,094	5
All other unions	196	113,922	6
Total	1136	1,887,823	100

This table shows that the strength of trade unionism lies in the five first-named groups of trades—mining; metal engineering and shipbuilding; textile; building; and railway, dock and other transport—which among them account for over three-quarters of the total membership.

In agriculture, trade unionism is at present practically non-existent, but in 1875 there were important unions of agricultural labourers, though at no time did they include any considerable proportion of the total agricultural population.

Taking the men belonging to all trade unions together, we find that their number does not amount to more than about one in five of the adult men who belong to the classes from which trade unionists are drawn. Only in a few groups do trade unionists form a high percentage of the total working population, *e.g.* coal-mining and cotton manufacture. The number of women belonging to trade unions at the end of 1906 was 162,453, distributed among 156 unions, of which, however, only 28 consisted exclusively of women. The great bulk of women trade unionists are found in the cotton trade, in which they actually outnumber the male members. Of all the women employed in factories and workshops, about one in twelve belongs to a trade union.

The available statistics with regard to the financial resources of trade unions, and their expenditure on various objects, are not so complete as those of membership, as the board of trade figures only relate to 100 of the principal unions. As, however, these unions include nearly two-thirds of the total membership, the figures showing their financial position may be accepted as being representative of the whole number of societies. In 1906 the income of these 100 societies was £2,344,157 or 36s. 9½d. per head; and their expenditure £1,958,676 or 30s. 9d. per head; and at the end of the year the funds in hand amounted to £5,198,536 or 81s. 7¼d. per head.

The actual rates of contribution per member vary greatly among the unions—from 7s. up to £4 per annum. Generally speaking, the highest income per member is found among the unions in the metal, engineering and shipbuilding group, where in 1905 it averaged £3, 5s. 7¼d., while the average in the mining unions was only £1, 4s. 1½d., and among dock labourers still lower. The metal trades and the textile unions appear to hold the highest amount of funds compared with their membership, the amounts at the end of 1905 being £6, 3s. 8¼d. and £6, 0s. 3d. per head respectively in these groups, while in the building trade unions it was only 18s. 8½d. and in some societies of unskilled labourers far less than this.

The main items of expenditure of trade unions are "dispute" benefit, "unemployed" benefit, various friendly benefits (including sick and accident, superannuation and funeral), and working expenses. The proportions of expenditure on these various objects naturally vary greatly in different groups of unions, and also in different years, some of the items being affected largely by the general state of employment, and the occurrence or absence of important disputes. On the basis, however, of an average of the ten years 1897–1906, the following analysis of the proportionate expenditure of the 100 principal unions on various classes of objects has been made: on disputes, 13·4%; on unemployed 22·1%; on friendly benefits (other than "unemployed"), 42·5%; on working expenses 22%. The 42·5% of expenditure on friendly benefits is made up of 19·1% on sick and accident, 12·4% on superannuation and 11% on funeral and other benefits.

The mining unions devoted 28·6% of their expenditure to the support of disputes (friendly benefits in this industry being largely provided by other agencies), while the unions in the printing and bookbinding trades only used 3·9% for this object, over three-quarters of their expenditure going to unemployed or friendly benefits. As illustrations of the variation in the expenditure by the same group of unions on a particular object from year to year, it may be stated that within the ten years' period referred to the annual expenditure of the metal, engineering and shipbuilding group on disputes varied from £514,637 in 1897, the year of the great engineering dispute, to £13,266 in 1899. Again, the expenditure of the same group of unions on unemployed benefit varied from £80,512 in 1899 to £303,749 in 1904. The burden of superannuation payments by the 100 unions has steadily increased during the ten years from £137,813 in 1896 to £306,089 in 1906.

At the end of 1906 there were 89 federations, including societies with a gross membership of over a million and three-quarters, but a considerable deduction must be made from this total on account of duplication. In the same year 231 "trades councils" were known to exist, with an affiliated membership of over 895,000.

The number of employers' associations and federations known to exist in the United Kingdom in 1906 was 953, including 60 federations and national associations. Of the total number of associations 398 are in the building trades.

II.—Foreign and Colonial

Modern trade unionism has had its chief development in English-speaking countries, and especially in the United Kingdom, where the conditions necessary for its growth have been present to the fullest extent. With some exceptions, such unions as are found elsewhere are either derived or copied from English organizations, or are associations with political objects. It is therefore unnecessary to give more than a brief summary of the position of trade unions in some of the principal countries and colonies outside the United Kingdom (for *United States* see IV. below).

Germany.—In Germany the majority of trade unions are of a political character, being closely connected with the Social Democratic party. These Socialist trade unions, termed "Gewerkschaften," were started by a congress held at Berlin in 1868, under the auspices of Fritscher and Schweitzer, two followers of Lassalle. In 1878 many of them were dissolved under the law prohibiting socialistic organizations, but shortly after their place was taken by local unions termed "Fachvereine," which ostensibly abstained from politics, but which in various ways succeeded in evading the law and carrying on the work of the Gewerkschaften. In 1887 a general committee of the German Gewerkschaften was formed, and in 1890 the General Commission of Trade Unions in Germany was established. Later years of prosperous trade have been marked by a rapid growth in the strength of trade unions in Germany.

The Social Democratic (Gewerkschaften) trade unions included in 1907 a membership of 1,886,147 as compared with 743,296 in 1902 and 419,162 in 1897. Of the total number of members in 1907, 1,865,506 belonged to branches affiliated to central federations; the membership of non-federated local unions being returned as only 20,641. The income of the federated trade unions in 1907 was £2,569,839, or over 27s. per member as compared with £554,887 (or about 15s. per member) in 1902 and £204,185 (or about 10s. per member) in 1897, and the expenditure in the same years to £2,156,126, £500,276 and £177,140 respectively. Of the 61 federations in existence in 1907, 43 paid travelling benefit, 42 paid unemployed benefit, 47 paid sick benefit and 57 paid funeral, removal and special allowance.

Another group of trade unions in Germany, less important as regards number and membership than the above, are the "Gewerkvereine," or non-political trade unions, sometimes known as "Hirsch-Duncker" unions, from the names of their founders. These unions were first formed in 1868, immediately after the Berlin congress referred to above. They were directly modelled on British trade unions. Since 1876 Social Democrats have been excluded. In their earlier years these unions suffered in membership from a series of unsuccessful strikes, and of late years they have been mostly benefit societies. In 1907 the Gewerkvereine embraced 108,889 members. Their income amounted to £77,068 in 1907 and their expenditure to £71,717.

Another group of unions, the Christian trade unions (Christliche Gewerkvereine), was formed in 1894. In 1907 the membership of this group was 354,760. The income of these unions in 1907 was £225,821, and the expenditure £167,867. Besides these groups of unions there were a number of independent societies with a membership of 96,684 in 1907.

It will be seen that German trade unions of one type or another included a membership of nearly two and a half millions in 1907, their membership having more than doubled in the last five years.

France.—In France combinations of workmen as well as of employers were prohibited by the laws of the 14th of June and the 28th of September 1792, which overthrew the old gild or corporation system. They were also penalized under various articles of the Penal Code, and it was not till 1864 that the prohibition was modified by law. At present the status of trade unions in France is regulated by the law of 1884, which repealed that of 1791 and modified the articles of the Penal Code so far as regards professional syndicates of employers or workmen. Since then there has been a considerable growth of workmen's unions, which in 1906 numbered 5322 with a membership of 896,012. Of the unions in existence in 1906, 3675 with a membership of 752,362 belonged to 187 federations. There is, however, some duplication owing to the fact that some unions belong to more than one federation. In 1906 there were 260,869 members of unions in the transport, warehousing, &c., groups of trades, 103,835 in the metal, 73,126 in the mining and quarrying, 78,854 in the textile, 66,678 in the building, 51,407 in the agricultural, forestry, fishing and cattle breeding, 48,353 in the food preparation trades and the remainder in various other trades.

Austria.—Apart from the Austrian gilds, membership of which is compulsory for persons engaged in non-factory handicrafts and trades (under a law of 1883) and in mining (under a law of 1896), there are a certain number of trade unions in Austria, though freedom of combined action among workmen is less complete than in many other European countries. Such right of combination as exists rests on the law of 1870, which removed the restrictions imposed by the Penal Code on combinations for influencing the conditions of labour. The impulse given to the formation of unions by this law, and by the advantages gained for the workmen during the years of prosperous trade that immediately followed, received a severe check during the succeeding depression of trade, when these advantages were mostly lost. Trade unionism did not revive until 1888, from which time the unions formed have mostly been on a Social Democratic basis, the majority being affiliated to a central organization in Vienna.

Since 1901 statistics relating to the trade unions of Austria have been published annually by the Central Trade Union Commission (Gewerkschafts-Kommission) at Vienna. In 1907 there were 5156 trade unions in particular trades, with a membership of 501,094, affiliated to the Social Democratic trade unions (Gewerkschaften). Of the total number of unions, 49 were central unions, 77 were district unions and 5030 were local unions. Of the total number of members 454,693 were males and 46,401 were females. The greatest membership, 84,085 in 1907, is shown to have been in the metal engineering and shipbuilding group of industries, the building trades coming next with 68,543 members. The transport trades showed a membership of 61,744, and the textile trades, 51,632. The chemical, glass and pottery trades included 54,469 members and the wood-working and furnishing group included 36,502 members. Food and tobacco trades accounted for 32,679, and mining and quarrying for 30,715 members.

The total receipts of the trade unions in 1907 amounted to £338,365 and the total expenditure to £297,822, excluding receipts and expenditure for disputes. The expenditure on account of disputes, for which £136,822 was collected by special free organizations of the branch unions, amounted to £76,066 in 1907.

There are besides these unions a number of general unions not confined to one trade, and trade-clubs—educational associations discharging to a greater or less extent trade union functions. These associations have, however, been excluded from the statistics published by the Gewerkschafts Kommission as not being trade unions proper.

Hungary.—The trade union movement in Hungary is of very recent growth. The membership of unions affiliated to the Central Federation at the end of 1907 is given in the *Volkwirtschaftliche Mitteilungen aus Ungarn* as 130,192, compared with 129,332 at the end of 1906. Independent local unions had a membership of 11,838 at the end of 1907. The largest groups of organized workers are in the building trade (35,630), metal workers (27,732), railway employees (17,192) and wood-workers (14,665).

Italy.—The *Bolletino* of the bureau of labour for August 1908 states that the membership of trade unions at the beginning of 1908 numbered 191,599 (in 2550 local unions). Included in the membership of 1908 are 48,877 building trades workers, 40,000 railway employés and 17,110 metal-trade workers. The agricultural labourers' trade unions were stated to have a membership of 425,983 at the beginning of 1908 as compared with 273,698 at the beginning of 1907.

Denmark.—In 1907 there were 99,052 members of 1249 trade unions in Denmark, and of these 78,081 were in unions affiliated to the National Federation. The largest unions in the Federation are those of the general labourers with 22,660 members; blacksmiths and machinists with 8000 members; masons, 5300 members; railway employés, 4990 members; carpenters, 3855 members; textile workers, 3700 members; and cabinet-makers, 3590 members.

Sweden.—In Sweden there were, in 1906, 126,272 members of 1596 trade unions, and of these 30,645 were factory workers (trades not specified), 24,485 were in unions connected with the metal trades, 10,706 were in the transport trades, 17,862 were in the wood-working trades, 7132 were in the food, &c., trades, 6602 were in the building trades, and 6005 were in the clothing trades.

Norway.—The trade union movement in Norway dates practically from 1884. At the end of 1906 there were 25,339 members of trade unions, as compared with 16,087 at the end of 1905. Of the membership in 1905, 5277 were iron and metal workers, 4910 journeymen (factory workers), and 1117 printers.

Holland.—In 1893 a National Labour Secretariat was formed, to which, in 1899, 45 societies with 13,050 members were said to be affiliated. After a general strike in April 1903 the membership of trade unions in Holland decreased considerably, the Secretariat losing half its members and several trade unions dissolving. In 1906 it was stated in the *International Report of the Trade Union Movement* that a new national centre of unions had been formed with trade unions affiliated to it, having a membership of 26,227, while the old centre still continued with a membership of 5000. The Diamond Workers' Federation, with a membership of over 8000, was affiliated with the new national centre.

The total number of members of trade unions at the end of 1906 is given as 128,845, 33,125 of these belonging to Christian organizations, while 95,720 belonged to other organizations.

Belgium.—The status of trade unions in Belgium is regulated by the law of 1898, under which they can be incorporated, provided that their objects are non-political and are confined to the furtherance of the interests of particular trades. Belgian trade unions, nevertheless, are mostly political in character, the majority being connected either with the Socialist-Labour, Catholic or Liberal parties. The membership of the Socialist-Labour group of unions in 1905 was 94,151, of the Catholic unions 17,814, of the free trade unions 34,833 and of the Liberal unions 1685, making a grand total of 148,483.

Of the 94,000 members of the Socialist-Labour unions, 60,000 are employed in mining, 11,500 in the textile industry and 7800 in the metal industry. Of the 17,800 in the Catholic trade unions, 5300 are in the textile trades, and 3200 in the building trades. Of the 35,000 in the free trade unions, 11,000 are in the textile industry, 6000 in the glass industry, 3600 in the applied art trades and 3300 in the printing and bookbinding trades.

Several organizations, *e.g.* the diamond workers, the printers' federation of Brussels, &c., are affiliated with the trade union committee without, however, joining the political organization. The Catholic and Liberal associations also do not affiliate with the other organizations.

British Dominions and Colonies.—Trade unionism has only developed to any considerable extent in a few of the industrial centres of the self-governing dominions. A great number of the unions in Canada are branches of organizations having their headquarters in the United States or in England. In July 1907 the *Canadian Labour Gazette* stated that of the 1593 local trade unions known to be in existence, 1346 were affiliated with central organizations of an international character. Besides these 1593 local trade unions, there were 8 congresses and national associations of labour, 49 trade and labour councils and 31 federations of trade unions known to be in existence.

Between 1876 and 1890 all the principal Australian states passed statutes more or less resembling the Trade Union Acts of the United Kingdom. A similar law was passed in New Zealand in 1878, but in this dominion and in some of the Australian states trade unions can now become incorporated and acquire a special legal status by registration as industrial unions under the laws relating to industrial conciliation and arbitration. In New Zealand there were, in 1906, 261 unions of workers with a membership of 29,869 and 133 unions of employers with a membership of 3276. In the years immediately preceding 1890 certain Australian unions, especially among the shearers and the seamen and wharf labourers, acquired great strength, and their determined attempts to secure a monopoly of employment for members of their organizations led to prolonged labour disputes in 1890 and 1891 (see Strikes and Lock-Outs), which resulted in the defeat of the unions and a consequent diminution of their membership and influence. More recently the unions have revived. They are encouraged by the laws relating to arbitration and conciliation, which (*inter alia*) permit preference for employment to be awarded to members of trade unions in certain circumstances.

Authorities.—For statistics of recent progress of trade unions, see reports on trade unions published by the board of trade (from 1887 onwards). Much information respecting trade unions is contained in the reports of the royal commission on trade unions (1867) and of the royal commission on labour (1891–1894). See also report of royal commission on trade disputes and trade combinations (1903–1906). The reports of the chief registrar of friendly societies give information with regard to trade unions registered under the Trade Union Acts. On the history and constitution of trade unions the fullest information is given in Webb's *History of Trade Unionism* and *Industrial Democracy*, both of which contain valuable bibliographical appendices which may be consulted as regards other sources of information respecting British trade unions. On trade unions abroad (besides the reports on foreign countries and the colonies of the royal commission on labour), see Kulemann's *Die Gewerkschaftsbewegung* (Jena, 1900), dealing with trade unions in all countries, and the board of trade "Abstract of Foreign Labour Statistics" and *Labour Gazette*, both of which give numerous references to the foreign official sources of information on trade unions, together with a summary of the statistics which they contain.

III.—Economic Effects of Trade Unionism

There is no general consensus of opinion as to the extent to which trade unions can attain success in achieving the objects which they set before themselves, or as to how far their action is beneficial or otherwise to the general community. One of the principal objects of trade unions being to maintain and increase the rates of wages paid to their members, the first question would be practically solved if statistical evidence were available to connect the course of wages with the action of combinations. Such evidence, however, is inconclusive. The period of growth of trade unionism in Great Britain has certainly been on the whole a period of rising wages. But many other causes tending to raise wages have been operative over the same period, and some of the facts might be explained as much by the tendency of rising wages to strengthen combinations as by that of combinations to raise wages.

Again, the observed fact that the rise has not been confined to industries in which organizations are strong might be explained either by the supposition that the rise brought about by trade unions has benefited a wider circle than their membership, or that the rise both within and outside the ranks of trade unions is due to causes other than their action. Perhaps the strongest statistical evidence of the power of trade unions to affect wages in particular districts is afforded by the local differences of wages in the same trade, which, it is contended, cannot be wholly explained by local differences of cost of living or industrial conditions, but which often correspond closely to differences of strength of trade union organization. This argument, however, does not touch the question of the effect of combination on the *general* level of wages.

Hardly more conclusive than the reasoning founded on statistics have been the attempts to solve the question by pure economic theory. During the prevalence of the old view of wages known as the "wage-fund" theory, combinations were usually held to be powerless to affect the general rate of wages, because they could not alter the proportion between capital and population, on which wages were thought to depend. The question however, was reopened by the change in theory which led economists to regard wages as depending primarily on the productivity of industry, and secondarily (and within comparatively narrow limits) on the relative power of bargaining as between the labourers or groups of labourers and the organizers of labour. According to this view, the effect of combinations on the rate of wages will ultimately depend, so far as the first and most important factor in the problem is concerned, on their effect on the general productiveness of industry. Prima facie, we might expect that trade unionism would, on the whole, restrict productiveness, and this is undoubtedly a view widely held among employers. Strictly professional associations tend generally to become conservative so far as methods of work are concerned; and even trade unions which may not "officially" oppose the introduction of new processes and the use of machinery may nevertheless serve to focus and make effective the hostility felt by the artisan towards methods of business organization which seem to him likely to decrease the demand for his services or to alter the conditions of work to his detriment. In some trades also trade unions are charged with encouraging or permitting their members to restrict the amount of work performed by them in a given time, with the short-sighted object of making more work for others. Many unions have attempted also with varying degrees of success to keep up the value of their labour by creating an artificial scarcity by restricting the numbers entering the trade, and have in various ways sought to control the management of business to a degree which must restrict the freedom of experiment on which the attainment of the maximum productiveness of industry must depend. By the resort to strikes—an essentially wasteful method of settling differences with employers—they have also to some extent restricted production, though the loss directly due to this cause is often exaggerated (see STRIKES AND LOCK-OUTS). Moreover, by their insistence on the payment to all workmen of a fixed "minimum" wage they have diminished the field for the profitable employment of the old and less capable, and may to some extent have discouraged the expert workman from earning and receiving the full reward of his extra ability.

On the other hand, it is claimed that trade unions have in many cases acted in the interests of industrial peace by restraining their members from ill-considered strikes, and that, by providing a recognized channel through which the workmen's grievances may find expression, they have often assisted in adjusting differences which would otherwise have led to the interruption of production. In particular they have frequently formed a convenient basis on which to build a system of conciliation or arbitration boards by which strikes are prevented (see ARBITRATION). It is also claimed that by protecting the "standard of life" of their members through the policy of securing a "minimum" rate of wages, trade unions may tend in the long run to build up a physically and industrially superior class of workmen, and thus ultimately increase the efficiency of industry.

The comparative weight of the above considerations differs according to the point of view from which the question is regarded. At any given time an individual employer may tend to feel most strongly the disadvantages of the restrictions under which he is placed by the action of a particular trade union, and may attach but little importance to the general effects, in the long run, on the national output of the pressure which such combinations exercise—which from the point of view of the general well-being of the community is by far the most important consideration. Generally speaking, any action of trade unions tending to diminish the efficiency and industry of the individual workman is as injurious to the community as to the individual employer, except in so far as such restriction may conceivably affect the health of the working community from over-strain. But the policy of "levelling up" the standard rate of wages, which may mean loss or ruin to a particular employer, may nevertheless act quite otherwise with respect to the national well-being, in so far as it tends to eliminate the "unfit" employer and to concentrate the industry in the hands of the more capable and more enterprising of the employing class, and in the localities most suited for the purpose. The pressure of rising wages has undoubtedly acted as a stimulus to the invention of labour-saving devices and the adoption of economical methods, as is shown in America, where the highest wages are often seen concurrently with the lowest labour cost. Advocates of trade unionism sometimes lay much stress on this aspect of their operation. On the other hand, it must not be forgotten that competition, both as between different grades of employing ability and of local advantages, is now international, and that the concentration of an industry in the most suitable localities and in the hands of the most capable organizers, which is claimed as a beneficial result of trade union action, may for any particular country mean the transference of the industry abroad; and this transference, especially in the case of industries dependent on export to neutral markets, may involve a considerable national loss.

Apart from the effect of trade unions on the total amount of the "national dividend," their supporters claim that they are able to alter the mode of distribution of this dividend. It is not usually claimed that they are able to affect the proportion of the total product which is paid as rent or interest for the use of the instruments of production, but that they can alter the proportions in which the residue is shared between the organizers of labour and the manual labouring class, to the advantage of the latter. The methods by which trade unions seek to achieve this result require separate examination.

The first group of methods are those which aim at creating a scarcity of some particular kind of labour so as to alter the relation of demand and supply. The particular methods employed for this purpose have been already sufficiently described. With regard to all of them it may be remarked that they are ineffective as regards the raising of the general rate of wages throughout the country (*i.e.* the average income per head of the manual labour classes), seeing that an artificial scarcity of one sort of labour implies a redundancy of some other kind. As regards the rate of wages in particular occupations there is no doubt but that at least for a time such methods may cause a considerable rise of wages, only limited at first by the imperfection of the control exercised by the union over the number competing in the labour market and by the extent to which the rise in the cost of production so caused is checked by the competition of goods imported from abroad, or of alternative commodities, or by the loss of foreign markets, or the diminution of home demand. But as time goes on other forces of a more subtle kind tend to come into play which further limit the power of the combination to keep up wages through restricting the supply of labour. Besides the substitution of alternative commodities, alternative processes of production may be invented, diminishing the demand for the services of the members of the exclusive trade union, while the artificial rise of wages is also likely to attract labour into the trade.

Generally speaking, it may be said that while the artificial restriction of the supply of workmen in a trade may raise wages for a time, it calls into play forces tending to restore the equilibrium of demand and supply by diminishing demand, and that these forces grow progressively stronger as time goes on, while the restrictive capacity of the combination usually tends to diminish. This is apart from the fact that restriction of the supply of labour entering a trade almost always involves the narrowing of the field of ability from which the trade can be recruited, and thus a lowering of the general standard of efficiency.

The other group of trade union methods which requires examination is that which aims at strengthening the economic position of the labourer by substituting collective for individual negotiations as regards wages, supported by a common reserve fund out of which the labourer may be maintained while waiting for his terms to be accepted. Undoubtedly these methods of mutual insurance and collective bargaining afford a powerful instrument for preventing "sweating" and for enabling the whole body of workmen to exact at the earliest moment and retain to the latest moment the full amount of the wages which a given state of trade and prices will enable the industry to support. The establishment of general working rules and standards of time or piece wages throughout a trade or district may also serve to protect the better and more capable employers against their more inefficient or unscrupulous competitors, and thus tend towards the survival of the "fittest" among the employing class. It is always to be remembered that the effect of collective bargaining is not in the long run one-sided. Combinations of workmen beget counter-combinations of employers, and the conditions of important industries tend to be settled more and more by "treaties" concluded between powerful bodies of employers and employed.

Were the combinations on both sides which enter into these agreements conterminous with the entire trades which they represent, and especially if the trades were protected from foreign competition, the interests of the general unorganized mass of consumers might conceivably suffer from these agreements.

As regards the future prospects of trade unions in Great Britain it is difficult to prophesy. The hopes of those who look for a universal expansion of these organizations so as to include the whole or the majority of the members of the manual-labour classes are probably extravagant. Not less chimerical is the expectation of the opponents of trade unions that a few defeats at the hands of determined employers or employers' organizations will permanently cripple them and lead to their decay and extinction. Probably for many years trade unions will include, as now, in their membership a powerful minority of the working classes, wielding an influence out of all proportion to their actual numbers. It is to be expected that experience and the spread of education may cause them gradually to abandon the rules and methods which interfere most with the economical application of labour and capital to industry.

Lastly, it may be pointed out that trade unionism has been the result of the growth of a class of manual workmen working for wages for employers who provide the materials and instruments of industry, and into whose ranks it is relatively difficult for the average workman to rise. It remains to be proved whether the class feeling which enables powerful trade unions to flourish can permanently be fostered and maintained except among workmen who expect to remain workmen most of their lives. If these conditions should be materially altered, trade unionism in its present form must decay or undergo a profound alteration. (X.)

IV.—United States

Trade unions in the United States are best treated from the broad standpoint of labour organizations generally, *i.e.* associations of wage-earners having for their general purpose the improvement of their members, either through a lessened working day, increased wages, or more satisfactory rules and conditions of employment. They may or may not admit employers, but as a rule they do not admit them. Sometimes they are formed for a specific purpose, like the Eight-Hours League, but generally they have platforms comprehending all the demands which labour usually makes. Labour organizations in the United States cannot be given a definite birthday. Prior to 1825 there were very few of them. In colonial days we have hints of their existence, but their purpose was partly political, and their membership often consisted of politicians. The purpose of the Caulkers' Club, in the early days of Massachusetts, was "to lay plans for introducing certain persons into places of trust and power." Tradition has it that the word "caucus" was derived from this club. It is also said that Samuel Adams's father, as early as 1724, was active in the club's work. There was probably a union of journeymen bakers in the city of New York in 1741 and of shoemakers in Philadelphia in 1792. The shipwrights of New York City were incorporated on the 3rd of April 1803, and the tailors and carpenters of that city were organized in 1806. The New York Typographical Society was in existence in 1817, and was probably organized in the early years of the 19th century. Peter Force was its president for a time, and Thurlow Weed was a member. A strike occurred in Mr Weed's office in 1821 on account of the employment of a non-union man, who was then designated a "rat." In 1823 was organized the Columbian Charitable Society of Shipwrights and Caulkers of Boston and Charlestown.

Labour Organizations.

The period from 1825 to 1860 may be called the formative period. About 1825, and for some years afterwards, there was a general discussion of socialistic theories, growing out of Robert Owen's experiments at New Lanark, in Scotland, and out of his communistic attempt at New Harmony, Indiana, in 1825. The wave of philosophic transcendentalism also, which swept over the country between 1825 and 1840, affected not only social but industrial life. Labour papers began to be established. The *Working Man's Advocate*, published in New York City in 1825, was probably the very first American labour journal. Soon afterwards there appeared the *Daily Sentinel* and *Young America*, projected by two Englishmen, George Henry Evans and Frederick W. Evans. The chief demands advocated by these journals were the freedom of public lands, the breaking up of monopolies, the adoption of a general bankruptcy law, a lien for the labourer upon his work for his wages, the abolition of imprisonment for debt, equal rights for women with men, and the abolition of chattel and wage slavery. These demands were endorsed by over 600 newspapers. In 1830 a Working-man's Convention was held in Syracuse, New York, the outcome of which was the nomination of Ezekiel Williams for governor. In 1832 a delegated convention which met in the state house at Boston initiated the 10-hours movement. The *Tribune* (New York), under the leadership of Horace Greeley, was opened to the advocacy of Fourierism, and so on all hands the movement towards organization was helped. In 1845 the New England Working Man's Association was organized, and such men as Charles A. Dana, George Ripley, Albert Brisbane, Wendell Phillips, William Lloyd Garrison, Theodore Parker, and others participated in its meetings. The first industrial congress of the United States was convened in the city of New York on the 12th of October 1845, but little came of it. Other and more important labour congresses were held in that city and in Chicago in 1847 and 1850 respectively. During the latter part of the formative period, that is, from 1825 to 1860, most of the great national trade unions that are now influential were projected and organized, though their great and rapid growth has been since the Civil War. The National Typographical Union was organized in 1852, its name being changed to International in 1862 in order to admit Canadian members; the National Union of Hat Finishers in 1854; the Iron Moulders' Union of North America on the 5th of July 1859; and in the same year the Machinists' and Blacksmiths' Union of North America. By 1860 the national unions already formed numbered 26.

Formative Period.

During the next few years, among other important organizations, were instituted what are known as the group of railway brotherhoods, the oldest and largest of which is the International Brotherhood of Locomotive Engineers. The grand division was founded at Detroit, Michigan, on the 17th of August 1863, under the name of the Brotherhood of the Footboard. The society was reorganized under its present title at Indianapolis, Ind., on the 17th of August 1864. The second national association of railway employés that was organized was the Conductors' Brotherhood, formed at Mendota, Illinois, on the 6th of July 1868, by the conductors from various railways in the United States. This brotherhood was recognized, and a general governing board established, on the 15th of December of the same year. Ten years later the name of the organization was changed from the Conductors' Brotherhood to the Order of Railroad Conductors of America. The Brotherhood of Locomotive Firemen was organized at Port Jervis, N.Y., on the 1st of December 1873. The Brotherhood of Railroad Trainmen was organized at Oneonta, N.Y., on the 23rd of September 1883. It was called the Brotherhood of Railroad Brakemen until the 1st of January 1890, when the present name was adopted. The Brotherhood of Railroad Trackmen is one of the younger and smaller organizations. The first efforts to found it were made in the spring of 1887, but its permanent organization took place a year later. The Brotherhood of Railroad Carmen of America was founded on the 9th of September 1890, by the consolidation of the Carmen's Mutual Aid Association, the Brotherhood of Railroad Car Repairers, the Car Inspectors, Repairers and Oilers' Protective Association and the Brotherhood of Railroad Carmen of Canada. The Switchmen's Union of North America is the outgrowth of the Switchmen's Mutual Aid Association, the present organization dating from 1897. Several of these railway brotherhoods suffered materially in their membership and influence through the organization of the American Railway Union in 1893.

Railway Brotherhoods.

The Cigar-Makers' National Union dates from 1864, the Bricklayers' and Masons' International Union from the 17th of

October 1865, the United States Wool Hat Finishers' Association from 1869 and the National Union of Horseshoers of the United States from 1875. The Amalgamated Association of Iron and Steel Workers resulted, as its name signifies, from the consolidation of various other orders and societies, the present order being organized at Pittsburg in August 1876. The consolidated societies were known previously to the new order of things as the United Sons of Vulcan, the Associated Brotherhood of Iron and Steel Heaters, Rollers and Roughers of the United States, and the Iron and Steel Roll Hands' Union. The oldest was the United Sons of Vulcan, originating in Pittsburg on the 17th of April 1858, and afterwards called the Iron City Forge. The organization is now known as the Amalgamated Association of Iron, Steel and Tin Workers. The Granite Cutters' National Union was organized in 1877, the Brotherhood of Carpenters and Joiners in 1881 and the Journeymen Bakers' National Union in 1886.

National Unions.

There have also been attempts to organize labour on a general or universal plan. The first of these was the International Association of Working-men, known as the "International," which was organized in London in the autumn of 1864. This society sought to associate working-men wherever manufacturing has been extended. The International grew for a while, but never at any time had a membership exceeding 100,000 and probably never over 50,000. It did not extend to the United States with much force; certainly no large number of the working-men of the country were involved in it, and branches were not organized in the union until 1870 or 1871.

The International.

The second attempt was the Noble Order of Knights of Labour of America, which was founded in Philadelphia on Thanksgiving Day 1869, through the efforts of Uriah S. Stephens and six associates, all garment-cutters. For several years the garment-cutters of Philadelphia had been organized as a trade union, but failed to maintain satisfactory rates of wages. Dissatisfaction prevailed, and resulted in the autumn of 1869 in the disbandment of the union. Stephens, who was a far-seeing man, and anticipated the disruption of his union, had prepared the outlines of a plan for an organization embracing, as he said, "all branches of honourable toil." He advocated education, co-operation and an intelligent use of the ballot as the proper means for gradually abolishing the present wage-system. The order had a varied career. Mr Stephens, himself a Mason, brought into the ritual of the new order many of the features of speculative Masonry. The obligations were in the nature of oaths, taken with much solemnity upon the Bible, and the members were sworn to the strictest secrecy. The order was known for a long time as "Five Stars," that designation being used in printing and writing. Many expressions taken from Greek literature were introduced into the ceremonies. The instructions given to every person admitted into the order are perhaps the best exponent of the nature of the ritual:—

Knights of Labour.

Labour is noble and holy. To defend it from degradation; to divest it of the evils to body, mind and estate which ignorance and greed have imposed; to rescue the toiler from the grasp of the selfish—is a work worthy of the noblest and best of our race. In all the multifarious branches of trade capital has its combinations; and, whether intended or not, they crush the manly hopes of labour and trample poor humanity in the dust. We mean no conflict with legitimate enterprise, no antagonism to necessary capital, but men, in their haste and greed, blinded by self-interests, overlook the interests of others and sometimes violate the rights of those they deem helpless. We mean to uphold the dignity of labour, to affirm the nobility of all who earn their bread by the sweat of their brows. We mean to create a healthy public opinion on the subject of labour (the only creator of values), and the justice of its receiving a full, just share of the values or capital it has created. We shall, with all our strength, support laws made to harmonize the interests of labour and capital, and also those laws which tend to lighten the exhaustiveness of toil. To pause in his toil, to devote to his own interests [*sic*], to gather a knowledge of the world's commerce, to unite, combine and co-operate in the great army of peace and industry, to nourish and cherish, build and develop, the temple he lives in, is the highest and noblest duty of man to himself, to his fellow men and to his Creator.

The ritual was neither printed nor written, and in all probability there is not now in existence a copy of it. So long as the utmost secrecy was retained the order did not grow rapidly; gradually it lost its secrecy and worked on more general plans. From the best evidence that can be secured it is probable that the first local assembly of the Knights of Labour was organized as early as 1873 in Philadelphia. Attempts at outside organization had been unsuccessful. The second assembly consisted of ship carpenters and caulkers employed in Cramp's shipyard. After this the order spread quite rapidly, 20 assemblies being organized in Philadelphia during 1873. A district assembly, consisting of delegates from local assemblies in Philadelphia, met in that city on Christmas Day 1873 and organized District Assembly No. 1. The order increased during the years following this action, and in 1877 delegates were chosen to organize a general assembly. These delegates met at Reading, Pennsylvania, on the 1st of January 1878, and organized the first general assembly, Mr Stephens, the founder, presiding as temporary chairman. Seven states were represented. General assemblies have been held each year since that time, and changes in the constitution or work of the order have been the subject of warm discussion. At the meeting of the first general assembly the membership must have been small, probably only a few thousand. It did not reach 50,000 till five years later. The general assembly of 1880, at Pittsburg, denounced strikes as injurious and not worthy of support except in extreme cases. At the fifth session, at Detroit, in 1881, the most important actions in the history of the order were taken, and from this session the rapid growth of the order may be dated. The assembly then declared that on and after the 1st of January 1882 the name and objects of the order should be made public. It also declared that women should be admitted upon an equal footing with men, and a strong committee was appointed to revise the constitution and the ritual. At the next general assembly, September 1882, in New York, the revised constitution was adopted, as well as laws and regulations for supporting strikes. After this the order began to grow rapidly. It antagonized the trade unions, the contention being that the order embraced higher and grander principles than those underlying the organization of the former. The trade unions in existence at that time struggled to preserve their organizations against what they considered the encroachment of the Knights of Labour. The high-water mark of the order was probably during 1883, 1884, 1885 and 1886, when, according to the very best information, it numbered not less than 1,000,000 members. In 1900 its membership was estimated at about 130,000.

The order of the Knights of Labour is based on the federal plan, and has a hierarchy of assemblies—the local assembly, the district assembly, the state and the general assembly. The officers of the local assembly consist of a master workman, worthy foreman, venerable sage, recording secretary, financial secretary, treasurer, worthy inspector, almoner, statistician and some minor officers. These are elected semi-annually by ballot or by acclamation. The district assembly is composed of duly accredited delegates from at least five local assemblies, and is the highest tribunal of the Knights of Labour within its jurisdiction under the general laws of the order. It has the power to levy assessments for its maintenance upon all locals, and has also the power to establish locals in the territory governed by it. The officers and their duties are similar to those of the local assembly, except that the master workman is called the district master workman. The constitution of the general assembly is a very imposing document, containing twenty articles. The assembly consists of representatives chosen by the district assemblies, and has full and final jurisdiction, being the highest tribunal of the order. It alone possesses the power and authority to make, amend or repeal the fundamental and general laws of the order, to decide finally all controversies arising, and to issue charters to state, district and local assemblies. The officers are elected at each annual session, and their titles correspond almost completely with those of the local and district assemblies, with the exception that the word "general" takes the place of "district," as "general master workman," &c. The general master workmen have been Uriah S. Stephens (the founder of the order), Terence V. Powderly, James R. Sovereign, John N. Parsons and Henry A. Hicks. The order has a publication known as the *Journal of the Knights of Labour*, published at Washington, D.C.

Organization.

The third attempt to bring into one order men employed in different vocations was the American Railway Union, organized in Chicago on the 20th of June 1893. It included all railway employés born of white parents. It was organized for the protection of members in all matters relating to wages and their rights as employés, and affirmed that such employés were entitled to a voice in fixing wages and in determining conditions of employment. The union won a great victory on the North-Western railway in April 1894, but its action in the great strikes in Chicago in 1894 cost it its life. Its membership reached at one time 150,000.

American Railway Union.

The separate unions found that the co-operation of other unions was needed to perfect and extend their work, and attempts were made from time to time to organize a federated body. The initial steps were taken in 1866, when the trades assemblies of New York City and Baltimore called a national labour congress, the 100 delegates sent by 60 secret and open organizations from different trade unions meeting on the 20th of August. In 1867 a second convention was called to meet in Chicago, the aim being to form a Trades Union Congress like that existing in Great Britain. The National Labour Union held two conventions in 1868, the first in May and the other in September; it met again in Chicago in 1869, in Boston in 1870, in Philadelphia in 1871 and in Columbus, Ohio, in 1872. This closed the experience of the National Labour Union. During 1873, owing to the industrial depression, many of the trade unions were suspended. An industrial congress met in Rochester, N.Y., in April 1874, consisting of some of the leading trade unionists of the United States, and on the 14th of that month a convention was held representing the Sovereigns of Industry. The expectation was that the old National Labour Union should be taken up. The Industrial Brotherhood of the United States, another secret order, partaking largely of the character of the Knights of Labour, was represented in that convention. As might have been expected, the two ideas—that on which the Knights of Labour was organized and the trade union idea—immediately became antagonistic, yet a platform containing most of the principles of the Knights of Labour was adopted. The movement ended with the Rochester meeting. The years 1875 and 1876 saw other attempts; but they were chiefly political in their character and the temporary orders then organized were disbanded. Between 1876 and 1881 other attempts were made at federation. A call issued jointly by the Knights of Industry and a body known as the Amalgamated Labour Union, consisting of some dissatisfied members of the Knights of Labour, resulted in a convention held at Terre Haute, Ind., on the 2nd of August 1881. The chief purpose was to supplant the Knights of Labour by the creation of a new secret order. The membership of the convention, however, had trade union proclivities and did not believe in multiplying labour societies. The secret organization was not effected. Another convention was held in Pittsburg, on the 19th of November 1881, as the result of the following statement:—

Federations of Labour.

> We have numberless trades unions, trades assemblies or councils, Knights of Labour, and various other local, national and international labour unions, all engaged in the noble task of elevating and improving the condition of the working classes. But great as has been the work done by these bodies, there is vastly more that can be done by a combination of all these organizations in a federation of trades and labour unions.

It is claimed that the 107 delegates represented 262,000 workmen. Their deliberations resulted in the Federation of Organized Trades and Labour Unions of the United States and Canada. Its platform differed but very little from that of the Knights of Labour, although it was in some respects more comprehensive. It demanded eight hours as a day's work; called for national and state incorporation of trade unions; favoured obligatory education of all children, and the prohibition of their employment under the age of fourteen; favoured the enactment of uniform apprentice laws; opposed bitterly all contract convict labour and the truck system for payment of wages; demanded laws giving to working men a first lien on property upon which their labour had been expended; insisted upon the abrogation of all so-called conspiracy laws; advocated the establishment of a national bureau of labour statistics; urged the prohibition of the importation of foreign labour; opposed government contracts on public work; favoured the adoption by states of an employers' liability act; and urged all other labour bodies to vote only for labour legislators. The second convention was held at Cleveland, O., on the 21st of November 1882.

The American Federation of Labour is the largest labour organization in the United States. It was organized at Columbus, O., on the 8th of December 1886, under the name it now bears. In 1888 it was declared that it owed its existence to the Federation of Organized Trades, &c., founded in 1881 at Pittsburg, and that the American Federation meetings or conventions should date from that year; hence it is generally stated that the Federation was founded in 1881. From the start in 1881 the Federation had a constitution, but it revised it at the convention held in Baltimore on the 16th of December 1887, under the name of the American Federation of Labour. The order is not secret, nor do individual members, through local trades unions or otherwise, owe any allegiance to it. Its object is the encouragement and formation of local trades and labour unions and the closer federation of such societies through the organization of central trades and labour unions in every state, and the combination of such bodies into state, territorial or provincial organizations for the purpose of securing general harmony not only in the interests of the working masses, but of legislation. While it is a federation, it cannot be called a federal body, like the Knights of Labour, although there are local trade unions, trade assemblies in cities and state federations; nevertheless, there is not the hierarchical character of the other body. Most of the trade unions in the United States are affiliated with the American Federation. The great railway brotherhoods are not so affiliated, except the Amalgamated Association of Railroad Employés of America, the Order of Railroad Telegraphers and the Brotherhood of Railroad Trackmen.

The federation has affiliated with it 117 international unions, 37 state federations, 574 city central bodies and 661 local trade and federal labour unions. The international unions are made up of approximately 28,500 local unions. The average membership on which dues have been paid was 264,825 in 1897, and ten years later the number was 1,538,970.

The chief officers of the federation are a president, first, second, third, fourth, fifth and sixth vice-presidents, treasurer and secretary. Samuel Gompers of New York was the first president, holding that position till 1894, when he was defeated through the endeavours of the Socialist Labour Party, and John M'Bride elected. At the next session, however, he was re-elected. The numerical strength of the American Federation of Labour is probably not far from 1,600,000. It maintains a journal called the *American Federationist*, published at Washington, D.C. The doctrine of the federation relative to strikes is that each affiliated society has its own government, distinct from the government of the national convention, which has no power to order strikes, such matters being left to the affiliated societies, but is advisory and not conclusive in its action.

Unions are often organized for temporary purposes, their existence ceasing as soon as the purposes succeed or fail. The total number of members of all kinds of labour organizations cannot be stated. There are many local societies and associations other than those belonging to the Knights of Labour or those affiliated with the American Federation of Labour, but which are distinctly labour bodies. According to the best possible classification there are 20,000,000 wage-earners in the United States, including men, women and children. The most liberal estimate of the membership of all labour organizations places the total at 2,000,000. This would be about 10% of the whole body of wage-workers; but in some occupations, like that of the printing trade, the organization probably includes from 75 to 90%.

Estimated Strength.

The law relating to trade unions varies somewhat in the different states. Both the federal legislature and several of the states (Massachusetts, New York, Pennsylvania, Michigan, Maryland, Iowa, Kansas and Louisiana) have passed laws permitting the incorporation of unions. Michigan, Wyoming and Nebraska have specially provided for incorporating assemblies of the Knights of Labour. Hardly any advantage, however, has been taken of these statutes. Some states have passed laws excepting trade unions from restrictions on combinations and conspiracies imposed by other statutes or the common law (*e.g.* New York), and especially from the operation of anti-trust laws (Michigan, Wisconsin, Nebraska, Montana, North Carolina and Texas). The Texas law, however, has been held unconstitutional. A number of states have passed laws, some of doubtful validity, prohibiting employers from making it a condition of employment that labourers should not belong to a union. Most states have adopted statutes legalizing union labels to indicate the products of members of trade unions.

By act of Congress, associations of the nature of labour organizations, having branches in several states or territories, may, on filing articles of association for record in Washington, become corporations. American legislation generally is friendly to trade unions. Their purposes are regarded as lawful by the courts, but if they use unlawful means for their accomplishments, a remedy will be applied. Injury to property, intimidation by threats, personal violence, or boycotts enforced by terrorism, are such unlawful means. The liberty of action thus secured to organizations of labour is equally the right of the employer. Therefore, a statute making it an offence for one to require those whom he employs to withdraw from a trade union is unconstitutional and void (see *Reports of American Bar Association*, xxi. 367, 372). The courts recognize that membership in trade unions is a species of property, of which no one can be deprived except through a formal procedure in conformity with the rules of the organization. Some of the states, notably New York, have a statute prohibiting trade unions from making any discrimination in connexion with their admission requirements on account of membership in the state militia or national guard.

TRADE WINDS, the name given to the winds which blow from the tropical belts of high pressure towards the equatorial belt of low pressure, from the north-east in the northern hemisphere and from the south-east in the southern. They are exceedingly regular, especially over the oceans, where there is no disturbing influence from the great land masses. They receive their name from this feature, the term "trade" being used in the otherwise obsolete sense of "direction" or "course" (cf. "tread"). The area of their greatest influence may be taken to extend from about 3° to 35° N., and from the equator to 28° S., though these belts are actually somewhat narrower at any given season, as the whole system of surface winds over the globe moves north and south following the sun. The westerly winds prevalent in the belts respectively north of the northern tropical belt of high pressure, and south of the southern, are sometimes known as anti-trades, their direction being opposite to that of the trade winds.

TRAFALGAR, BATTLE OF. The British victory over the French off Cape Trafalgar, fought on the 21st of October 1805, was a sequel of the breakdown of Napoleon's great scheme for the invasion of the British Isles (See Napoleonic Campaigns: *Naval*). When Villeneuve gave up in despair the attempt to enter the Channel, he steered for Cadiz, and anchored in that port on the 20th of August 1805. He found three British ships of the line, under the command of Vice-Admiral Cuthbert Collingwood, on the watch. Collingwood, resolved that the allies should not drive him through the Straits of Gibraltar without being compelled to follow, retired slowly, and at a short distance ahead of the ships sent to pursue him. They, not being willing to be drawn into the Mediterranean, gave up the pursuit. The British officer then resumed his watch off Cadiz. On the 22nd of August he was joined by Rear-Admiral Sir Richard Bickerton with four ships of the line, and on the 30th by Vice-Admiral Sir Robert Calder with 18. The allied fleet, consisting of 29 sail of the line which had come with Villeneuve, and five already at Cadiz, 34 in all, remained quiescent. The use to be made of it, or the measures to be taken for its destruction, were matters of urgent consideration to Napoleon and to the British government. On the 14th of September Napoleon gave orders that the French and Spanish ships at Cadiz should put to sea at the first favourable opportunity, join seven Spanish ships of the line then at Cartagena, go to Naples, and land the soldiers they carried to reinforce his troops then in that kingdom, and should fight a decisive action if they met a British fleet of inferior numbers. Two Spanish ships of the line were to be counted as equal to one French. Their final destination was to be Toulon. On the 15th he decided that Villeneuve, whose "excessive pusillanimity" rendered him incapable of vigorous action, must be replaced by Admiral Rosily. Rosily received his orders on the 17th and left for Cadiz. The British government, determined to confine the allies to Cadiz, or beat them if they came out, sent Nelson to take command and prepared to despatch reinforcements. Nelson left Portsmouth on the 15th of September, and reached Cadiz on the 28th, bringing three ships of the line with him. He gave orders that no salute should be fired for him lest the enemy should learn that reinforcements had arrived. The bulk of the fleet—23 sail—was kept well out at sea, and five ships of the line under Rear-Admiral Louis were appointed to cruise close to Cadiz as an inshore squadron. On the 5th of October Louis was sent to Gibraltar to renew his provisions and water, and the watch was left to two frigates. Between the 7th and the 13th of October Nelson was joined by six ships of the line, making a total of 34. But Admiral Calder, having been summoned home to stand a court-martial, took his flagship with him on the 14th, and on the 17th another line-of-battle ship had to be detached to renew her stores. As Admiral Louis could not return before the battle of the 21st, Nelson had at his disposal 27 ships of the line in all. Napoleon's order of the 14th of September reached Villeneuve on the 28th. He learnt also that Rosily was coming, but not that he himself was to be superseded. On the 5th of October he held a council of war of French and Spanish officers. They decided that the condition of their ships did not justify them in hoping for victory over the British fleet, but Napoleon's orders were peremptory, and they agreed that a sortie must be made. Easterly winds were needed to facilitate the sailing of a large and awkward fleet from Cadiz, and till the 14th the wind was hard from the west. Even when it fell the allies lingered. On the 18th of October Villeneuve heard that Rosily had reached Madrid, and of his own supersession. Stung by the prospect of being disgraced before the fleet, he resolved to go to sea before his successor could reach Cadiz.

The allies, aided by a light land breeze which blew from the east, though the wind at sea was westerly, began to leave Cadiz Bay on the 19th. Their movements were at once known to the British look-out frigates, and were transmitted by signal to Nelson, who was cruising some thirty miles to the west. During the period of blockade he had instructed his captains as to how he meant to fight the approaching battle. The memorandum in which his instructions were embodied was dated the 9th of October. It was drawn up in view of the circumstances which did not arise—that the enemy would come to sea with a strong easterly wind which would give him the weather gage; that he might be reinforced to a strength of over 50 ships of the line from Brest, Rochefort and Cartagena; that the British fleet might be raised by reinforcements to 40 ships. But the governing principles of the memorandum were independent of such details. They were that the order of sailing in which the fleet was when the enemy was seen was to be the order of battle; that no time was to be wasted in forming a precise line; that the attack was to be made in two bodies, of which one, to be led by the second in command, Collingwood, was to be thrown on the rear of the enemy, while the other, led by Nelson himself, was to take care that the centre and van should not come to the assistance of the ships cut off. Nelson was careful to point out that "Something must be left to chance. Nothing is sure in a sea fight beyond all others"; and he left his captains free from all hampering rules by telling them that "No captain can do very wrong if he places his ship alongside that of the enemy." In short the execution was to be as circumstances should dictate, subject to the guiding rule that the enemy's rear was to be cut off and a concentration of superior force on an inferior sought for.

The uncertainties of naval warfare in the days of sailing ships were fully shown at Trafalgar. The allies, having left Cadiz on the 20th of October, were 33 sail of the line strong, one of the fleet having been left behind. They sailed in five squadrons. Three were nearer the land than the other two. The leading squadron of the three was commanded by the Spanish admiral, Álava; Villeneuve followed; and the French admiral, Dumanoir, commanded the rear. The other two squadrons of six ships of the line each, commanded by the Spanish admiral, Gravina, and the French admiral, Magon, were parallel with, and outside of the three. All headed for the Straits of Gibraltar in the westerly breezes, which had become very light. The British fleet of 27 sail in two divisions also headed for the Mediterranean. During the night of the 20th–21st of October several movements were made to gain position, and there was an inevitable tendency to straggle among vessels which did not all sail equally well and were moving in light winds. On the early morning of the 21st the allies were some twelve miles off Cape Trafalgar. The British fleet was some ten or twelve miles out at sea to the west of them. Seeing that a battle would now be forced on him, Villeneuve ordered his whole fleet to turn so as to bring their heads on Cadiz. He was painfully aware that the incomparably more expert British fleet would not be content to attack him in the old-fashioned way, coming down in a parallel line and engaging from van to rear. He knew that they would endeavour to concentrate on a part of his line. But Villeneuve was too conscious of the inexperience of his officers and men to think it possible to make counter movements with them. It has been said that the French and Spanish ships which had taken part in the late cruise to the West Indies and back must be considered as trained in the same sense as the British. But apart from the fact that these vessels formed little more than a half of the allied fleet, the comparison is childish. It could only have occurred to writers who, wishing to exalt the glory of Trafalgar, forget that the superior quality of the British fleet, the fruit of foresight, of good sense, and the strenuous work of a people, was itself the best of all claims to honour. A hasty cruise across the Atlantic and back was no equivalent for years of training. The blockades maintained by the British fleet had made it difficult for the allies to obtain stores and their ships were ill fitted. Their crews contained a minute proportion of men bred to the sea, and as they had to be taught the elements of seamanship on the few occasions when they got to sea, their gunnery was neglected. There was valour in the allied fleet, but there was neither skill nor confidence. Moreover the very light wind then blowing rendered manœuvring all but impossible for the most expert crews. Villeneuve could do nothing more than order his fleet to turn so as to bring the ships' heads on Cadiz, to form the line, and await the enemy's attack. He, however, left his captains free to act for the best when the battle had begun, by telling them that whoever was not under fire was not at his post. The movement of conversion ordered at 6 o'clock a.m. was not executed till about 10 o'clock, and it was ill done. The three squadrons nearest the shore turned first, the rear beginning, to leave room for the others. Thus Dumanoir now led the van and Álava followed Villeneuve. The two squadrons of Gravina and Magon, which had been outside, fell in behind Álava. No accurate line was formed. The allies drifted rather than sailed into a curve of some five miles long, stretching from north to south, concave on the west side, and more pronounced at the southern than at the northern end. Their ships did not follow one another, but were in many cases two, and in some cases three, abreast in groups. To some extent this was to their advantage, as the effective range of fire of the artillery of the day was barely 1200 yds., and as the power of concentrating the fire of guns out of ports was limited, the danger to an assailant bearing down was not great during his approach. The peril was that he would be engaged with two or three enemies when he had broken into the line, and this risk was increased by the accidental group formation of the allies.

The confidence and promptitude of the British fleet presented a marked contrast to the passivity of the allies. When in the early morning the enemy was seen to the east, Nelson's fleet was in two divisions, somewhat scattered—his own of 12 sail of the line being to the westward and windward in the light breeze from W.N.W.; Collingwood's of 15 sail being to leeward and east. At 6.40 the signal was made to form the order of sailing and prepare for battle. The enemy's movement of conversion was already seen, and it was obvious that unless he were rapidly stopped he might reach Cadiz Bay in safety. A few minutes before 7 o'clock the signal to bear up, No. 76, was made by Nelson. Much discussion has arisen as to whether this was an order to bear up together, or in succession; the first if exactly executed would have caused the British ships to approach the enemy in a line abreast (side by side) since all would have turned at once; the second would have caused them to approach in a line ahead (one after the other) since they would have turned successively. The discussion is in reality futile, because the want of wind rendered it impossible to arrange exact formations, because it had been decided that no time should be wasted in dressing the line, and because Nelson's flagship, the "Victory" (100), and Collingwood's flagship, the "Royal Sovereign" (100), were quick-sailing vessels, and both admirals moved at the best attainable speed. The slow ships could not keep up with them. The two squadrons went down heading to north of east, Collingwood to the right and leeward, Nelson to the north and windward, in two bodies without exact formation, according to the speed of the ships. Collingwood headed for the centre, and the pronounced curve at the south end of the allied line caused the ships of his division to come into action in a close approach to a parallel with the enemy. The "Royal Sovereign" was the first British ship to break into the enemy's line, which she did about midday and astern of Álava's flagship the "Santa Ana." She was alone for a few minutes, but the ships of Collingwood's division, as they sailed into the curve, were mostly able, by steering to the right, to get into action very soon after their admiral. Nelson's division was headed by himself to cut through the enemy between his van and centre, and to bar his road to Cadiz. It was certainly in a nearer approach to a line ahead than Collingwood's. After making a demonstration at the allied van, he broke into their line astern of the "Bucentaure" (100), the flagship of Villeneuve.

The exact movements of all the ships engaged could only be given in a very detailed account of the battle, but the main lines of the action are already indicated. To the allies it appeared that the British fleet assailed them in two lines converging on their centre, and that it then carried out a concentration on this part of their line. Though this is too simple—or too bald—a statement of the case, it does not go far from the truth. The allied formation was broken in two, and though the rear part was kept well in play by Collingwood's division, the severest blows fell on the central sections.

The battle, which began at midday, was terminated about five. Eighteen of the allies were taken. Their van, after long remaining quiescent, made a futile demonstration, and then sailed away. The four van ships which escaped with

Admiral Dumanoir were met and captured off Cape Ortegal on the 4th of November by a British squadron of five ships under Sir Richard Strachan. The stormy weather which followed the battle gave the enemy an opportunity to retake some of the prizes, and others were lost. Four only were carried into Gibraltar by the British fleet—three French and one Spanish. Only eleven of the allied fleet succeeded in finding safety in Cadiz. The fragment of the French squadron remained there under Admiral Rosily till he was forced to surrender to the Spaniards in 1808 on the breaking out of the Peninsular War. The loss of life of the allies cannot be stated with precision. In the British fleet the reported loss in killed and wounded was 1690, of whom 1452 belonged to 14 out of the 27 ships of the line present—the inequality of loss being mainly due to the fact that it was as a rule these vessels which came earliest into action. For the circumstances of Nelson's death see the article NELSON.

AUTHORITIES.—Accounts of the battle of Trafalgar are to be found in all the naval, and most of the general, histories of the time. The most essential of the original authorities are collected by Sir N. Harris Nicolas in his *Despatches and Letters of Vice-Admiral Lord Viscount Nelson*, vol. vii. (London 1844–1846). The controversy as to the exact method on which the battle was fought, and the significance of the signal to bear down, is fully worked out with many references to authorities in *The Times* from the 14th of July to the 21st of October 1905, both in a general correspondence and in a series of articles on "Trafalgar and the Nelson Touch," 16th, 19th, 22nd, 26th, 28th and 30th of September 1905; see also J. S. Corbett, *The Campaign of Trafalgar* (1910). (D. H.)

TRAFFIC, properly the interchange or passing of goods or merchandise between persons, communities or countries, commerce or trade. The term in current usage is chiefly applied collectively to the goods, passengers, vehicles and vessels passing to and fro over the streets, roads, sea, rivers, canals, railways, &c.

The origin of the word is obscure. It occurs in Fr. *trafique*, and *trafiquer*, Ital. *traffico*, *trafficare*, Sp. *trafago*, *trafagar*. Du Cange (*Gloss. Med. et Inf. Lat.*) quotes the use of *traffigare* from a treaty between Milan and Venice of 1380, and gives other variants of the word in medieval Latin. There is a medieval Latin word *transfegator*, an explorer, spy, investigator (see Du Cange, *op. cit.*, *s.v.*) which occurs as early as 1243, and is stated to be from *transfegare*, a corruption of *transfretare*, to cross over the sea (*trans*, across, *fretum*, gulf, strait, channel). Diez (*Etymologisches Wörterbuch der romanischen Sprachen*) connects the word with Port. *trasfegar*, to decant, which he traces to Late Lat. *vicare*, to exchange, Lat. *vicis*, change, turn. A suggestion (*Athenaeum*, app. 7, 1900) has been made that it is to be referred to a late Hebrew corruption (*traffik*) of Gr. τροπαϊκός, pertaining to a trophy, applied to a silver coin with the figure of victory upon it and termed in Latin *victoriatus*.

TRAHERNE, THOMAS (1637?–1674), English writer, was, according to Anthony à Wood, a "shoemaker's son of Hereford." He entered Brasenose College, Oxford, in 1652, and after receiving his degree in 1656 took holy orders. In the following year he was appointed rector of Credenhill, near Hereford, and in 1661 received his M.A. degree. He found a good patron in Sir Orlando Bridgeman, lord keeper of the seals from 1667 to 1672. Traherne became his domestic chaplain and also "minister" of Teddington. He died at Bridgeman's house at Teddington on or about the 27th of September 1674. He led, we are told, a simple and devout life, and was well read in primitive antiquity and the fathers. His prose works are *Roman Forgeries* (1673), *Christian Ethics* (1675), and *A Serious and Patheticall Contemplation of the Mercies of God* (1699). His poems have a curious history. They were left in MS. and presumably passed with the rest of his library into the hands of his brother Philip. They then became apparently the possession of the Skipps of Ledbury, Herefordshire. When the property of this family was dispersed in 1888 the value of the MSS. was unrecognised, for in 1896 or 1897 they were discovered by Mr W. T. Brooke on a street bookstall. Dr Grosart bought them, and proposed to include them in his edition of the works of Henry Vaughan, to whom he was disposed to assign them. He left this task uncompleted, and Mr Bertram Dobell, who eventually secured the MSS., was able to establish the authorship of Thomas Traherne. The discovery included, beside the poems, four complete "Centuries of Meditation," short paragraphs embodying reflexions on religion and morals. Some of these, evidently autobiographical in character, describe a childhood from which the "glory and the dream" was slow to depart. Of the power of nature to inform the mind with beauty, and the ecstatic harmony of a child with the natural world, the earlier poems, which contain his best work, are full. In their manner, as in their matter, they remind the reader of Blake and Wordsworth. Traherne has at his best an excellence all his own, but there can be no reasonable doubt that he was familiar both with the poems of Herbert and of Vaughan. The poems on childhood may well have been inspired by Vaughan's lines entitled *The Retreat*. His poetry is essentially metaphysical and his workmanship is uneven, but the collection contains passages of great beauty.

See Bertram Dobell's editions of the *Poetical Works* (1906) and *Centuries of Meditation* (1908).

TRAILL, HENRY DUFF (1842–1900), British author and journalist, was born at Blackheath on the 14th of August 1842. He belonged to an old Caithness family, the Traills of Rattar, and his father, James Traill, was stipendiary magistrate of Greenwich and Woolwich. H. D. Traill was sent to the Merchant Taylors' School. He rose to be head of the school and obtained a scholarship at St John's College, Oxford. He was destined for the profession of medicine and took his degree in natural sciences in 1865, but then read for the bar, being called in 1869. In 1871 he received an appointment in the education office which left him leisure to cultivate his gift for literature. In 1873 he became a contributor to the *Pall Mall Gazette*, then under the editorship of Frederick Greenwood. He followed Greenwood to the *St James's Gazette* when in 1880 the *Pall Mall Gazette* took for a time the Liberal side, and he continued to contribute to that paper up to 1895. In the meantime he had also joined the staff of the *Saturday Review*, to which he sent, amongst other writings, weekly verses upon subjects of the hour. Some of the best of these he republished in 1882 in a volume called *Recaptured Rhymes*, and others in a later collection of *Saturday Songs* (1890). He was also a leader-writer on the *Daily Telegraph*, and acted for a time as editor of the (Sunday) *Observer*. In 1897 he became first editor of *Literature*, when that weekly paper (afterwards sold and incorporated with the *Academy*) was established by the proprietors of *The Times*, and directed its fortunes until his death. Traill's long connexion with journalism must not obscure the fact that he was a man of letters rather than a journalist. He wrote best when he wrote with least sense of the burden of responsibility. His playful humour and his ready wit were only given full scope when he was writing to please himself. One of his most brilliant *jeux d'esprit* was a pamphlet which was published without his name soon after he had begun to write for the newspapers. It was called *The Israelitish Question and the Comments of the Canaan Journals thereon* (1876). This told the story of the Exodus in articles which parodied very cleverly the style of all the leading journals of the day, and was at once recognized as the work of a born humorist. Traill sustained this reputation with *The New Lucian*, which appeared in 1884 (2nd ed., with several new dialogues, 1900); but for the rest his labours were upon more serious lines. He directed the production of a vast work on *Social England* in 1893–1898; he wrote, for several series of biographies, studies of Coleridge (1884), Sterne (1882), William III. (1888), Shaftesbury (1886), Strafford (1889), and Lord Salisbury (1891); he compiled a biography of Sir John Franklin, the Arctic explorer (1896); and after a visit to Egypt he published a volume on the country, and in 1897 appeared his book on Lord Cromer, the man who had done so much to bring it back to prosperity. Of these the literary studies are the best, for Traill possessed great critical insight. He published two collections of essays: *Number Twenty* (1892), and *The New Fiction* (1897). In 1865 his *Glaucus; a tale of a Fish*, was produced at the Olympic Theatre with Miss Nellie Farren in the part of Glaucus. In conjunction with Mr Robert Hichens he wrote *The Medicine Man*, produced at the Lyceum in 1898. He died in London on the 21st of February 1900.

TRAIN (M. Eng. *trayn* or *trayne*, derived through Fr. from Late Lat. *trahinare*, to drag, draw, Lat. *trahere*, cf. trail, trace, ultimately from the same source), a general term applied to that which is drawn or trailed behind or after anything else, the hind part or rear of anything. It is thus used of the portion of a skirt, robe or cloak which is lengthened behind so that when allowed to fall it trails along the ground. In ceremonial processions and other state functions the duty of keeping raised the train of the sovereign's robes, or of the robes of great officials and dignitaries, is assigned to pages or to official train-bearers. The length of the train which ladies must wear at royal courts, drawing-rooms or other state functions is fixed by regulations from the lord chamberlain's office. The chief specific uses of the term are for the trail of a gun, that portion of the carriage which rests upon the ground when it is unlimbered, the line of gunpowder or other combustible material which is used to ignite a charge of explosives, and, figuratively, to an ordered series or sequence of events, thoughts, &c. The most familiar application is to a number of carriages, wagons or trucks coupled together and drawn by a locomotive engine on a railway (see RAILWAYS). A special use of the verb "to train," in the sense of to educate, to instruct, to bring into fit and proper condition, mental, moral or physical, is developed, as in "educate" (Lat. *educare*, literally, to draw out), from the sense of drawing or bringing out the good qualities aimed at in a course of instruction; a specific use is that of training for a race or other form of athletics, *i.e.* getting into fit physical condition.

TRAJAN [MARCUS ULPIUS TRAJANUS] (A.D. 53–117), Roman emperor, was born at Italica, in Spain, on the 18th of September 52 (or 53). The family to which he belonged was probably Italian and not Iberian by blood. His father began as a common legionary soldier, and fought his way up to the consulship and the governorship of Asia. The younger Trajan was rigorously trained by him, and imbued with the same principles and tastes. He was a soldier born and bred. No better representative of the true old hardy Roman type, little softened by either luxury or education, had come to the head of affairs since the days of Marius. His training was almost exclusively military, but his experience as an officer gave him an acquaintance with almost every important province of the empire, which was of priceless value to him when he came to the throne. For ten years he held a commission as military tribune, which took him to many lands far asunder; then he filled important posts in Syria and Spain. By the year 89 he had achieved a considerable military reputation. At that time L. Antonius Saturninus headed a rebellion in Germany, which threatened seriously to bring Domitian's rule to an end. Trajan was ordered in hot haste from Further Spain to the Rhine. Although he carried his troops over that long and arduous march with almost unexampled rapidity, he only arrived after the insurrection had been put down. But his promptitude raised him higher in the favour of Domitian, and he was advanced to the consulship in 91. Of the next five years of his life we know nothing definite. It is not unlikely that they were spent at Rome or in Italy in the fulfilment of some official duties. When the revolution of 96 came, and Nerva replaced the murdered Domitian, one of the most important posts in the empire, that of consular legate of Upper Germany, was conferred upon Trajan. An officer whose nature, as the event showed, was interpenetrated with the spirit of legality was a fitting servant of a revolution whose aim it was to substitute legality for personal caprice as the dominant principle of affairs. The short reign of Nerva really did start the empire on a new career, which lasted more than three-quarters of a century. But it also demonstrated how impossible it was for any one to govern at all who had no claim, either personal or inherited, to the respect of the legions. Nerva saw that if he could not find an Augustus to control the army, the army would find another Domitian to trample the senate under foot. In his difficulties he took counsel with L. Licinius Sura, a lifelong friend of Trajan, and on the 27th of October in the year 97 he ascended the Capitol and proclaimed that he adopted Trajan as his son. The senate confirmed the choice and acknowledged the emperor's adopted son as his successor. After a little hesitation Trajan accepted the position, which was marked by the titles of imperator, Caesar and Germanicus, and by the tribunician authority. He immediately proceeded to Lower Germany, to assure himself of the fidelity of the troops in that province, and while at Cologne he received news of Nerva's death (Jan. 25, 98). The authority of the new emperor was recognized at once all over the empire. The novel fact that a master of the Romans should have been born on Spanish soil seems to have passed with little remark, and this absence of notice is significant. Trajan's first care as emperor was to write to the senate an assurance like that which had been given by Nerva, that he would neither kill nor degrade any senator. He ordered the establishment of a temple and cult in honour of his adoptive father, but he did not come to Rome. In his dealings with the mutinous praetorians the strength of the new emperor's hand was shown at once. He ordered a portion of the force to Germany. They did not venture to disobey, and were distributed among the legions there. Those who remained at Rome were easily overawed and reformed. It is still more surprising that the soldiers should have quietly submitted to a reduction in the amount of the donative or gift which it was customary for them to receive from a new emperor, though the civil population of the capital were paid their largess (*congiarium*) in full. By politic management Trajan was able to represent the diminution as a sort of discount for immediate payment, while the civilians had to wait a considerable time before their full due was handed to them.

The secret of Trajan's power lay in his close personal relations with the officers and men of the army and in the soldierly qualities which commanded their esteem. He possessed courage, justice and frankness. Having a good title to military distinction himself, he could afford, as the unwarlike emperors could not, to be generous to his officers. The common soldiers, on the other hand, were fascinated by his personal prowess and his camaraderie. His features were firm and clearly cut; his figure was tall and soldierly. His hair was already grey before he came to the throne, though he was not more than forty-five years old. When on service he used the mean fare of the common private, dining on salt pork, cheese and sour wine. Nothing pleased him better than to take part with the centurion or the soldier in fencing or other military exercise, and he would applaud any shrewd blow which fell upon his own helmet. He loved to display his acquaintance with the career of distinguished veterans, and to talk with them of their battles and their wounds. Probably he lost nothing of his popularity with the army by occasional indulgence in sensual pleasures. Yet every man felt and knew that no detail of military duty, however minute, escaped the emperor's eye, and that any relaxation of discipline would be punished rigorously, yet with unwavering justice. Trajan emphasized at once his personal control and the constitutionality of his sway by bearing on his campaigns the actual title of "proconsul," which no other emperor had done. All things considered, it is not surprising that he was able, without serious opposition from the army, entirely to remodel the military institutions of the empire, and to bring them into a shape from which there was comparatively little departure so long as the army lasted. In disciplinary matters no emperor since Augustus had been able to keep so strong a control over the troops. Pliny rightly praises Trajan as the lawgiver and the founder of discipline, and Vegetius classes Augustus, Trajan and Hadrian together as restorers of the morale of the army. The confidence which existed between Trajan and his army finds expression in some of the coins of his reign.

For nearly two years after his election Trajan did not appear in Rome. He had decided already what the great task of his reign should be—the establishment of security upon the dangerous north-eastern frontier. Before visiting the capital he determined to put affairs in train for the attainment of this object. He made a thorough inspection of the great lines of defence between the Danube and the Rhine, and framed and partly carried out a vast scheme for strengthening and securing them.

The policy of opposing uncivilized tribes by the construction of the *limes*, a raised embankment of earth or other material, intersected here and there by fortifications, was not his invention, but it owed in great measure its development to him. It is probable that the northernmost part of the great *limes Germaniae*, from the Rhine at Rheinbrohl, nearly midway between Coblenz and Bonn, to a point on the Main east of Frankfort, where that river suddenly changes its course from north to west, was begun by Domitian. The extension of this great barrier southwards to the point at which it met the *limes Raetiae* was undertaken by Trajan, though we cannot say how far he carried the work, which was not entirely completed till long after his time. We may without hesitation follow the opinion of Mommsen, who maintains that the *limes* was not intended, like Hadrian's Wall between the Tyne and the Solway, and like the great wall of China, to oppose an absolute barrier against incursions from the outside. It was useful as marking definitely the boundary of the Roman sway, and as assuring the Romans that no inroad could be made without intelligence being had of it beforehand, while the *limes* itself and the system of roads behind it enabled troops to be directed rapidly to any threatened point, and the fortified positions could be held against large numbers till reinforcements arrived. Great importance was no doubt attached to the perfection of the lines of communication bearing on the *limes*. Among a people of roadmakers, Trajan was one of the greatest, and we have definite evidence from inscriptions that some of the military roads in this region were constructed by him. The more secure control which the Romans now maintained over the territory within the *limes* tended to its rapid civilization, and the Roman influence, if not the Roman arms, soon began to affect powerfully the regions beyond.

After his careful survey of the Rhine end of the frontier defences, Trajan proceeded to strengthen them in the direction of the Danube. From the age of Tiberius onwards the Romans possessed the whole southern bank of the river from its source to the Euxine. But the precarious tenure of their possession had been deeply impressed on them by the disasters and humiliations they had undergone in these districts during the reign of Domitian. A prince had arisen among the Dacians, Decebalus by name, worthy to be placed at the head of all the great barbarian antagonists of Rome. Like Maroboduus, he was able to combine the forces of tribes commonly hostile to each other, and his military ability almost went the length of genius. Domitian attacked him but was compelled to make an ignominious peace. He agreed to pay to Decebalus an annual subsidy, and to supply him with engineers and craftsmen skilled in all kinds of construction, but particularly in the erection of fortifications and defensive works. During the nine or ten years which had elapsed since the conclusion of this remarkable treaty the Dacian prince had immensely strengthened the approaches to his kingdom from the Roman side. He had also equipped and drilled his formidable army after the Roman fashion. It was impossible for a soldier like Trajan to endure the conditions accepted by Domitian; but the conquest of Dacia had become one of the most formidable tasks that had ever confronted the empire. Trajan no doubt planned a war before he left the Danube for Rome late in 99.

The arrival of the emperor had been awaited in the capital with an impatience which is expressed by Pliny and by Martial.[1] As he entered the city and went on foot to the Capitol the plaudits of the people were unmistakably genuine. During his stay in the city he riveted more firmly still the affections both of the senate and of the people. The reconciliation of the empire with liberty, inaugurated, as Tacitus says, by Nerva, seemed now to be securely achieved. Trajan was absolutely open and simple, and lived with men at Rome as he had lived with his soldiers while on service. He realized the senate's ideal of the citizen ruler. The assurance that no senator should suffer was renewed by oath. All the old republican formalities were most punctiliously observed—even those attendant on the emperor's election to the consulate, so far as they did not involve a restoration of the old order of voting at the comitia. The veneration for republican tradition is curiously attested by the reproduction of many republican types of coin struck by senatorial officers. Trajan seized every opportunity for emphasizing his view that the *princeps* was merely the greatest of the magistrates, and so was not above but under the laws. He was determined, he said, to be to his subjects such a ruler as he had desired for himself when a subject. Real power and influence were accorded to the senate, which had now, by the incorporation of members whose origin was provincial, become in a manner representative of the whole empire. Trajan associated with the senators on equal terms, and enjoyed in their company every kind of recreation. All pomp was distasteful to him and discarded by him. There was practically no court, and no intrigues of any kind were possible. The approach to his house was free, and he loved to pass through the city unattended and to pay unexpected visits to his friends. He thirsted for no senator's blood, and used severity against the *delatores* alone. There was but one insignificant conspiracy against him during his whole reign. Though not literary himself, Trajan conciliated the literary men, who at all times had close relations with the senate. His intimate, M. Licinius, played an excellent Maecenas to his Augustus. In his efforts to win the affections of Roman society Trajan was aided by his wife Plotina, who was as simple as her husband, benevolent, pure in character, and entirely unambitious. The hold which Trajan acquired over the people was no less firm than that which he maintained upon the army and the senate. His largesses, his distributions of food, his public works, and his spectacles were all on a generous scale. The exhibitions in the arena were perhaps at their zenith during his tenure of power. Though, for some unexplained reason, he abolished the mimes, so beloved of the populace, at the outset of his reign, he availed himself of the occasion of his first triumph to restore them again. The people were delighted by the removal of the imperial *exedra* (a large chamber with open front) in the circus, whereby five thousand additional places were provided. Taxation was in many directions reduced, and the financial exactions of the imperial officers controlled by the erection of a special court. Elaborate precautions were taken to save Italy from famine; it is said that corn for seven years' consumption at the capital was retained in the granaries. Special encouragement was given to merchants to import articles of food. The corporation of bakers was organized and made more effective for the service of the public. The internal trade of Italy was powerfully stimulated by the careful maintenance and extension of the different lines of road. But the most striking evidence of Trajan's solicitude for his people's welfare is found in his institution of the *alimenta*, whereby means were provided for the rearing of poor and orphan children in Italy. The method had been sketched out by Nerva, but its great development was due to Trajan. The moneys allotted by the emperor were in many cases supplemented by private benevolence. As a soldier, Trajan realized the need of men for the maintenance of the empire against the outer barbarians, and he preferred that these men should be of Italian birth. He was only carrying a step farther the policy of Augustus, who by a system of rewards and penalties had tried to encourage marriage and the nurture of children. The actual effect of Trajan's regulations is hard to measure; they were probably more effectual for their object than those of Augustus. The foundations were confiscated by Pertinax, after they had existed less than a century.

On the 1st of September in the year 100, when Trajan was consul for the third time, Pliny, who had been designated consul for a part of the year, was appointed to deliver the "Panegyric" which has come down to us, and forms a most important source of our knowledge concerning this emperor. Pliny's eulogy of Trajan and his denunciation of Domitian are alike couched in extravagant phrases, but the former perhaps rests more uniformly on a basis of truth and justice than the latter. The tone of the "Panegyric" certainly lends itself to the supposition of some historians that Trajan was inordinately vain. That the emperor had an honest and soldierly satisfaction in his own well-doing is clear; but if he had had anything like the vanity of a Domitian,

[1] It has been conjectured, not improbably, that the *Germania* of Tacitus, written at this period, had for one of its aims the enlightenment of the Romans concerning the formidable character of the Germans, so that they might at once bear more readily with the emperor's prolonged absence and be prepared for the necessity of decisive action on the frontier.

the senate, ever eager to outrun a ruler's taste for flattery, would never have kept within such moderate bounds.

On the 25th of March in the year 101 Trajan left Rome for the Danube. Pretexts for a Dacian war were not difficult to find. Although there was no lack of hard fighting, victory in this war depended largely on the work of the engineer. The great military road connecting the posts in Upper Germany with those on the Danube, which had been begun by Tiberius, was now extended along the right bank of the river as far as the modern Orsova. The campaign of 101 was devoted mainly to road-making and fortification. In the following campaign, after desperate fighting to the north of the Danube in the mountainous region of Transylvania, Sarmizegethusa, the capital of Decebalus, was taken, and he was forced to terms. He agreed to raze all fortresses, to surrender all weapons, prisoners and Roman deserters, and to become a dependent prince under the suzerainty of Rome. Trajan came back to Italy with Dacian envoys, who in ancient style begged the senate to confirm the conditions granted by the commander in the field. The emperor now enjoyed his first Dacian triumph, and assumed the title of Dacicus. At the same time he royally entertained the people and no less royally rewarded his brave officers. But the Dacian chief could not school his high spirit to endure the conditions of the treaty, and Trajan soon found it necessary to prepare for another war. A massive stone bridge was built across the Danube, near the modern Turn Severin, by Apollodorus, the gifted architect who afterwards designed the forum of Trajan. In 105 began the new struggle, which on the side of Decebalus could now only lead to victory or to destruction. The Dacians fought their ground inch by inch, and their army as a whole may be said to have bled to death. The prince put an end to his own life. His kingdom became an imperial province; in it many colonies were founded and peopled by settlers drawn from different parts of the empire. The work done by Trajan in the Danubian regions left a lasting mark upon their history. The emperor returned to the capital in 106, laden with captured treasure. His triumph outdid in splendour all those that went before it. Games are said to have been held continuously for four months. Ten thousand gladiators are said to have perished in the arena, and eleven thousand beasts were killed in the contests. Congratulatory embassies came from all lands, even from India. The grand and enduring monument of the Dacian wars is the noble pillar which still stands on the site of Trajan's forum at Rome.

The end of the Dacian wars was followed by seven years of peace. During part of that time Pliny was imperial legate in the provinces of Bithynia and Pontus, and in constant communication with Trajan. The correspondence is extant and gives us the means of observing the principles and tendencies of the emperor as a civil governor.

The provinces (hitherto senatorial) were in considerable disorder, which Pliny was sent to cure. It is clear from the emperor's letters that in regard to nine out of ten of the matters which his anxious and deferential legate referred to him for his decision he would have been better pleased if the legate had decided them for himself. Trajan's notions of civil government were, like those of the duke of Wellington, strongly tinged with military prepossessions. He regarded the provincial ruler as a kind of officer in command, who ought to be able to discipline his province for himself and only to appeal to the commander-in-chief in a difficult case. In advising Pliny about the different free communities in the provinces, Trajan showed the same regard for traditional rights and privileges which he had exhibited in face of the senate at Rome. At the same time, these letters bring home to us his conviction that, particularly in financial affairs, it was necessary that local self-government should be carried on under the vigilant supervision of imperial officers. The control which he began in this way to exercise, both in Italy and in the provinces, over the "municipia" and "liberae civitates," by means of agents entitled (then or later) "correctores civitatium liberarum," was carried continually farther and farther by his successors, and at last ended in the complete centralization of the government. On this account the reign of Trajan constitutes a turning-point in civil as in military history. In other directions, though we find many salutary civil measures, yet there were no far-reaching schemes of reform. Many details in the administration of the law, and particularly of the criminal law, were improved. To cure corruption in the senate the ballot was introduced at elections to magistracies. The finances of the state were economically managed, and taxpayers were most carefully guarded from oppression. Trajan never lacked money to expend on great works of public utility; as a builder, he may fairly be compared with Augustus. His forum and its numerous appendages were constructed on a magnificent scale. Many regions of Italy and the provinces besides the city itself benefited by the care and munificence which the emperor bestowed on such public improvements. His attitude towards religion was, like that of Augustus, moderate and conservative. The famous letter to Pliny about the Christians is, according to Roman ideas, merciful and considerate. It was impossible, however, for a Roman magistrate of the time to rid himself of the idea that all forms of religion must do homage to the civil power. Hence the conflict which made Trajan appear in the eyes of Christians like Tertullian the most infamous of monsters. On the whole, Trajan's civil administration was sound, careful and sensible, rather than brilliant.

Late in 113 Trajan left Italy to make war in the East. The never-ending Parthian problem confronted him, and with it were more or less connected a number of minor difficulties. Already by 106 the position of Rome in the East had been materially improved by the peaceful annexation of districts bordering on the province of Syria. The region of Damascus, hitherto a dependency, and the last remaining fragment of the Jewish kingdom, were incorporated with Syria; Bostra and Petra were permanently occupied, and a great portion of the Nabataean kingdom was organized as the Roman province of Arabia. Rome thus obtained mastery of the most important positions lying on the great trade routes between East and West. These changes could not but affect the relations of the Roman with the Parthian Empire, and the affairs of Armenia became in 114 the occasion of a war. Trajan's campaigns in the East ended in complete though brilliant failure. In the retreat from Ctesiphon (117) the old emperor tasted for almost the first time the bitterness of defeat in the field. He attacked the desert city of Hatra, westward of the Tigris, whose importance is still attested by grand ruins. The want of water made it impossible to maintain a large force near the city, and the brave Arabs routed the Roman cavalry. Trajan, who narrowly escaped being killed, was forced to withdraw. A more alarming difficulty lay before him. Taking advantage of the absence of the emperor in the Far East, and possibly by an understanding with the leaders of the rising in Armenia and the annexed portions of Parthia, the Jews all over the East had taken up arms at the same moment and at a given signal. The massacres they committed were portentous. In Cyprus 240,000 men are said to have been put to death, and at Cyrene 220,000. At Alexandria, on the other hand, many Jews were killed. The Romans punished massacre by massacre, and the complete suppression of the insurrection was long delayed, but the Jews made no great stand against disciplined troops. Trajan still thought of returning to Mesopotamia and of avenging his defeat at Hatra, but he was stricken with sickness and compelled to take ship for Italy. His illness increasing, he landed in Cilicia, and died at Selinus early in August 117.

Trajan, who had no children, had continually delayed to settle the succession to the throne, though Pliny in the "Panegyric" had pointedly drawn his attention to the matter, and it must have caused the senate much anxiety. Whether Hadrian, the relative of Trajan (cousin's son), was actually adopted by him or not is impossible to determine; certainly Hadrian had not been advanced to any great honours by Trajan. Even his military service had not been distinguished. Plotina asserted the adoption, and it was readily and most fortunately accepted, if not believed, as a fact.

The senate had decreed to Trajan as many triumphs as he chose to celebrate. For the first time a dead general triumphed. When Trajan was deified, he appropriately retained, alone among the emperors, a title he had won for himself in the field, that of "Parthicus." He was a patient organizer of victory rather than a strategic genius. He laboriously perfected the military machine, which when once set in motion went on to victory. Much of the work he did was great and enduring, but the last year of his life forbade the Romans to attribute to him that *felicitas* which they regarded as an inborn quality of the highest generals. Each succeeding emperor was saluted with the wish that he might be "better than Trajan and more fortunate than Augustus." Yet the breach made in Trajan's *felicitas* by the failure in the East was no greater than that made in the *felicitas* of Augustus by his retirement from the right bank of the Rhine. The question whether Trajan's Oriental policy was wise is answered emphatically by Mommsen in the affirmative.

It was certainly wise if the means existed which were necessary to carry it out and sustain it. But succeeding history proved that those means did not exist. The assertion of Mommsen that the Tigris was a more defensible frontier than the desert line which separated the Parthian from the Roman Empire can hardly be accepted. The change would certainly have created a demand for more legions, which the resources of the Romans were not sufficient to meet without danger to their possessions on other frontiers.

The records of Trajan's reign are miserably deficient. Our best authority is the 68th book of Dio Cassius; then comes the "Panegyric" of Pliny, with his correspondence. The facts to be gathered from other ancient writers are scattered and scanty. Fortunately the inscriptions of the time are abundant and important. Of modern histories which comprise the reign of Trajan the best in English is that of Merivale; but that in German by H. Schiller (*Geschichte der römischen Kaiserzeit*, Gotha, 1883) is more on a level with recent inquiries. There are special works on Trajan by H. Francke (Güstrow, 1837), De la Berge (Paris, 1877), and Dierauer in M. Büdinger's *Untersuchungen zur römischen Kaisergeschichte*, (Leipzig, 1868). A paper by Mommsen in *Hermes*, iii. pp. 30 seq., entitled "Zur Lebensgeschichte des jüngeren Plinius," is important for the chronology of Trajan's reign. The inscriptions of the reign, and the Dacian campaigns, have been much studied in recent years, in scattered articles and monographs. (J. S. R.)

TRALEE, a market town and seaport, and the county town of Co. Kerry, Ireland, on the Ballymullen or Leigh River, about a mile from its mouth in Tralee Bay, and on the Great Southern & Western railway. Pop. (1901), 9687. A ship canal, permitting the passage of ships of 200 tons burden, connects it with Tralee Bay. Large vessels discharge at Fenit, 8 m. westward, where there is a pier connected with Tralee by rail. Coal, iron and timber are imported, and there is a considerable export of grain. There is a large trade in butter. Railways serve the neighbouring seaside watering-places of Ballybunnion and Castlegregory, and the coast scenery of this part is grand and varied. Four miles north-west of Tralee is Ardfert, with its cathedral, one of the oldest foundations in Ireland, now united to the see of Limerick. St Brendan was its original founder, and it had once a university. A neighbouring round tower fell in 1870. Seven miles north of this again is the fine round tower of Rattoo.

Tralee, anciently Traleigh, the "strand of the Leigh," owes its origin to the foundation of a Dominican monastery in 1213 by John Fitz-Thomas, of the Geraldine family. During the reign of Elizabeth it was in the possession of Earl Desmond, on whose forfeiture it came into possession of the Dennys. At the time of the rebellion in 1641 the English families in the neighbourhood asked to be placed in the castle under the charge of Sir Edward Denny, but during his absence a surrender was made. The town was incorporated by James I., and returned two members to the Irish parliament. Though disfranchised at the Union in 1800, it obtained the privilege of returning one member in 1832, but in 1885 it was merged in the county division. It is governed by an urban district council.

TRALLES (mod. *Güzel Hissar*), an ancient town of Caria, Asia Minor, situated on the Eudon, a tributary of the Maeander. It was reputed an Argive and Thracian colony, and was long under Persian rule, of which we hear in the history of Dercyllidas' raid from Ephesus in 397 B.C. Fortified and increased by the Seleucids and Pergamenians, who renamed it successively Seleucia and Antiochia, it passed to Rome in 133. Though satirized in a famous line (Juv. *Sat.* iii. 70) as a remote provincial place, it had many wealthy inhabitants in the Roman period and, to judge by objects discovered there, contained many notable works of art. Two of the best marble heads in the Constantinople museum came from Tralles; and both in the excavations conducted for that museum by Edhem Bey (1904), and by chance discoveries, fine-art products have come to light on the site. Rebuilt by Andronicus II. about 1280, it was superseded a few years later, after the Seljuk conquest, by a new town, founded by the amir Aidin in a lower situation (see AIDIN). (D. G. H.)

TRAMORE, a market village and seaside resort of Co. Waterford, Ireland, on the bay of the same name, 7 m. S. of the city of Waterford, and the terminus of the Waterford & Tramore railway. The situation is pleasant, and the neighbouring coast exhibits bold cliff scenery. The bay is open to the south, and is dangerous to navigators, as in foggy weather it has been frequently mistaken for the entrance to Waterford Harbour. On the cliffs to the west are three towers, one having a curious iron figure known as the "metal man," erected as a warning to sailors. The bay is divided into an outer part and an inner lagoon (the Back Strand) by a spit of sand, with a strait, crossed by a ferry at its eastern extremity. A monument commemorates the wreck of the troopship "Seahorse" in 1816. Four miles west is Dunhill Castle, well situated on a precipitous rock.

TRAMP, a vagrant, one who "tramps" or walks the roads begging from house to house or ostensibly looking for work, but with no home and habitually sleeping out or moving on from the casual ward of one workhouse to that of another (see VAGRANCY). The word is the shortened form of "tramper," one who tramps or walks with heavy tread. The term "tramp" is also used of a cargo steamer not running on a regular line but passing from port to port where freight may be picked up.

TRAMWAY, a track or line of rails laid down in the public roads or streets (hence the American equivalent "street railway"), along which wheeled vehicles are run for the conveyance of passengers (and occasionally of goods) by animal or mechanical power; also a light roughly laid railway used for transporting coals, both underground and on the surface, and for other similar purposes. The word has been connected with the name of Benjamin Outram, an engineer who, at the beginning of the 19th century, was concerned in the construction of tram roads, and has been explained as an abbreviation for "Outram way." But this is clearly wrong, since the word is found much earlier. It appears to be of Scandinavian origin and primarily to mean a beam of wood, cf. Old Swedish *tråm*, *trum*, which have that sense. In a will dated 1555 reference is made to amending a "higheway or tram" in Bernard Castle, where a log road seems to be in question. In Lowland Scottish "tram" was used both of a beam of wood and specifically of such a beam employed as the shaft of a cart, and the name is still often given in England to the wheeled vehicles used for carrying coal in mining. "Tramway," therefore, is primarily either a way made with beams of wood or one intended for the use of "trams" containing coal (see RAILWAY).

Construction.—The first tramway or street railway designed for passenger cars with flanged wheels was built in New York in 1832. The construction of this tramway does not appear to have been a success, and it was soon discontinued. In 1852 tramways were revived in New York by a French engineer named Loubat, who constructed the track of flat wrought-iron rails with a wide, deep groove in the upper surface, laid on longitudinal timbers. The groove, which was designed for wheel flanges similar to those employed on railways, proved dangerous to the light, narrow-tired vehicles of the American type. To meet this difficulty a step-rail consisting of a flat plate with a step at one side raised about $\frac{7}{8}$ in. above the surface was designed and laid at Philadelphia in 1855. When tramways were first introduced into England by G. F. Train in 1860 a rail similar to that laid at Philadelphia was adopted. This rail (fig. 1) was made of wrought-iron and weighed 50 lb per yard. It was 6 in. wide and had a step $\frac{3}{4}$ in. above the sole. The rails were spiked to longitudinal timbers, which rested on transverse sleepers, and they were laid to a gauge of 4 ft. $8\frac{1}{2}$ in. Tramways of this type were laid at Birkenhead in 1860, at London in 1861, and in the Potteries (North Staffordshire) in 1863. The English public, however, would not tolerate the danger and obstruction caused by the step-rail, with its large area of slippery iron surface, and the tramway laid in London had to be removed, while those at Birkenhead and the Potteries were only saved by being relaid with grooved rails. Thus, while the step-rail became the standard form used in the United States, the grooved-rail became generally adopted in Europe. From the tramway point of view the step-rail has many advantages. A groove collects ice and dirt, and on curves binds the wheel flanges, increasing the resistance to traction. A grooved rail is, however, far less of a nuisance to the ordinary vehicular traffic, and it has come to be largely used in the principal cities of America.

After the passing of the Tramways Act of 1870 the construction of tramways proceeded rapidly in England. A flat grooved rail supported on a longitudinal timber and laid on a concrete bed was generally adopted. The paving consisted of stone setts from

(Figs. 2 and 3 from D. K. Clarke's *Tramways, their Construction and Working*, by permission of Crosby Lockwood & Son.)

FIG. 1. FIG. 2. FIG. 3.

Early Tramway Rails.

4 to 6 in. in depth, laid on a thin bed of sand and grouted with cement, mortar or a bituminous mixture. With the exception of the design of the rail and the manner of supporting it on the concrete foundation, which has continually changed, this method of constructing the track has varied but little to the present day.

The flat section of rail which was wanting in vertical stiffness soon proved unsatisfactory. A fillet or flange was then added to each side, which, bedding into the supporting timber, not only increased the vertical strength but also prevented horizontal displacement of the rail. With the addition of the side flanges a greatly improved method of fixing the rail to the sleepers was adopted. The old vertical spike, which was a crude fastening, was replaced by a "dog" or double-ended side spike, one end of which was driven through a hole in the flange of the rail (fig. 2). This fastening was very strong and proved a great improvement.

The next change was the use of cast-iron chairs to support the rails, which were introduced by Kincaid in 1872. These led to a modification of the rail section, and instead of the two side flanges a rail with a central flange (fig. 3) which fitted into the cast-iron chairs was used. The chairs weighed about 75 lb each, and were spaced at intervals of about 3 ft. The Barker rail laid in Manchester in 1877 was somewhat similar to that shown in fig. 3, but a continuous cast-iron chair was used to support it.

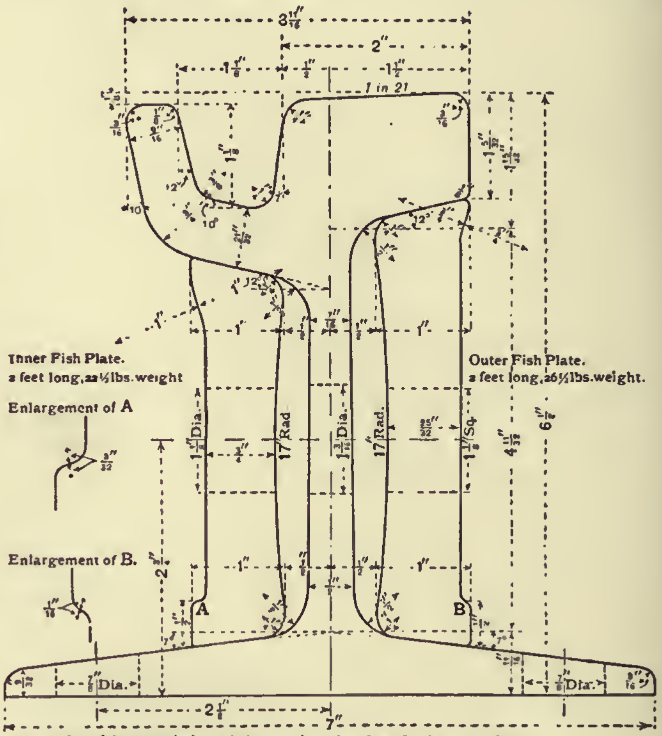
The introduction of steam traction about 1880, with its heavier axle loads and higher speeds, was a severe test of the permanent way. The flat section laid on timber sleepers and the built-up rails of the Kincaid and Barker types began to be discarded in favour of the solid girder rail rolled in one piece. The solidity and depth of this section gave it great vertical stiffness, and its introduction materially assisted in solving the problem of providing a smooth and serviceable joint.

The merits of the girder rail soon caused it to be generally adopted, and although the design has been greatly improved it remains to-day the standard form of tramway rail used throughout the world. At first difficulty was experienced in rolling the heavier sections with thin webs and wide bases, but the introduction of steel and improvements in the rolling mills overcame these troubles. The early girder rails laid about 1880 usually weighed from 70 to 80 lb per lineal yard, and were 6 or 6½ in. deep. The groove varied from 1 to 1⅛ in., and the tread was about 1¾ in. in width. The fish-plates were not designed to give any vertical support, and were merely used to keep the rail ends in line. The girder rails were either bedded directly on the foundation or spiked to timber sleepers which were buried in the concrete.

The form of head adopted for tramway rails in Europe has almost universally been one with the groove on one side. With this section the wheel flange forces out the dirt clear of the tread. In a few isolated cases a centre grooved rail has been used. As with railways, the adoption of many different gauges has led to much inconvenience. This want of uniformity in the gauge is in some parts of the country a great obstacle to the construction of inter-urban lines. London and the larger provincial towns adopted the standard gauge of 4 ft. 8½ in., but in many towns narrow gauges of 3 ft. or 3 ft. 6 in. were laid. Glasgow and a few other towns adopted the gauge of 4 ft. 7¾ in. with a view of making the narrow grooved rail of the tramways available for railway wagons, but without any real success.

With the introduction of electric traction the weight and speed of the cars greatly increased, and experience soon proved that only the most substantial form of permanent way was capable of withstanding the wear and tear of the traffic. The early electric lines were laid with girder rails weighing about 75 lb per lineal yard. These proved to be too light, and, at the present time, rails weighing from 95 to 110 lb per lineal yard are in general use. The large number of rail sections designed a few years ago gave considerable trouble to makers of rails. The issue in 1903 by the Engineering Standards Committee of a set of standard girder tramway rail sections was therefore generally welcomed. The sections comprise rails of five different weights. Modified sections for use on curves were also published, together with a standard form of specification. Fig. 4 shows the section of the 100 lb. B.S. rail (No. 3).

Tramway rails are generally ordered in 45 ft. lengths. Rails 60 ft. long are sometimes used, but they are difficult to handle, especially in narrow streets. The rail joints still prove the weakest part of the track. Numerous patents have been taken out for fish-plates and sole-plates of special design, but none has proved quite satisfactory. The "Dicker" joint, in which the head of the rail on the



(Reproduced by permission of the Engineering Standards Committee.)

FIG. 4.—British Standard Tramway Rail, No. 3.

tread side is partly cut away and the fish-plate carried up so that the wheel runs on its top edge, and the "anchor" joint, in which a short piece of inverted rail is bolted or riveted to the undersides of the abutting rails, have been largely used. The latter makes a good stiff joint, but when buried in concrete it interferes with the bedding of the rail as a whole, often causing it to work loose in the centre. Various processes have also been introduced for uniting the ends of the rails by welding. Electric welding was first tried in the United States about 1893, and has since been considerably used in that country. In this process two specially prepared fish-plates are applied, one to each side of the joint. Each fish-plate has three bosses or projections, one in the centre opposite the joint and one near each end. By passing a heavy alternating current of low voltage between the opposite bosses the fish-plates are welded to the rail. The current is obtained from the line by means of a motor-generator and static transformer. Another process which has been used considerably in the United States, and at Coventry and Norwich in England, is the cast-welded joint. To make this joint the rail ends are enclosed in an iron mould filled with molten cast-iron, which makes a more or less perfect union with the steel rails. The great drawback to these two processes is the costly and cumbersome apparatus required. The "thermit" process (see WELDING) does not require any large initial outlay, and has been applied to welding the joints on both old and new tracks. The cost of making each joint is about £1.

Points and crossings are used on a tramway to deflect a car from one road to another. In the days of horse traction no movable switch was used, the car being guided by making the horses pull the leading wheels in the required direction. With the introduction of mechanical traction a movable switch was fitted in one of the castings to act as a guide to the wheel flanges. On modern tramways the points consist of a pair of steel castings, one being a fixed or dummy point, and the other containing a movable switch. On a single track at passing places the cars in Great Britain always take the left-hand road, and a spring is fitted to hold the movable switch to lead in that direction. The bottom of the grooves at open points and crossings are raised so that the car wheel runs on its flange over the break in the tread of the rail. Double switch points in which the two tongues are connected are sometimes laid. In recent years the size and weight of the castings and the length of the movable switches have considerably increased. Manganese steel is very generally used for the tongues and sometimes for the whole casting. Ordinary cast steel with manganese steel inset pieces at the parts which wear most quickly are a feature of the later designs. At some junctions the points are moved by electric power.

While the form of concrete foundation remains the same as that laid at Liverpool in 1868, far greater care is now given to the bedding of the rails. After the excavation has been completed the rails are set up in the trench and carefully packed up to the finished level. The concrete is then laid and packed under the rail, generally for a depth of 6 in. When the surface is to be paved with stone setts bedded on sand the concrete may be left rough, but where wood is to be laid the surface must be floated with fine mortar and finished to a smooth surface. Both hard and soft wood blocks are used for paving. Wood should not be used unless the whole width of the carriage-way is paved. Many different qualities of stone setts have been laid. Hard granite such as that supplied from the quarries near Aberdeen is the most suitable.

In urban districts the road authorities almost always require the tramway surface, *i.e.* between the rails and for 18 in. on either side, to be paved. In country districts many tramways have been laid with only a sett edging along each rail, the remainder of the surface being completed with either ordinary or tarred macadam. This construction, however, is only suitable on roads with very light traffic. After a tramway is laid, especially in a macadamized road, the heavy vehicular traffic use the track, and the wear is very much greater than on other parts of the carriage-way.

Steam and Cable Tramways.—Horse traction, especially in hilly districts, has many limitations, and early in the history of tramways experiments were made both with steam cars and cable haulage. Although experimental steam cars were tried in England in 1873 the first tramways which regularly employed steam engines were French, though the engines were supplied by an English firm. About 1880 many improvements were made in the design of the engines employed, and this form of traction was adopted on several tramways in England. Beyond requiring a better constructed track it does not necessitate any modifications in the general design of the permanent way. The first cable tramway was constructed at San Francisco in 1873. In England the first cable system was a short length at Highgate in 1884. Cable tramways were also laid down at Edinburgh, Birmingham, Matlock and Brixton (London). Cable traction, with the expensive track construction it necessitates, and the limited speed of haulage, belongs to the past. Only gradients too severe to be worked by ordinary adhesion will in the future justify its use. The construction of the conduit or tube in which the cable runs adds very considerably to the cost of the permanent way. On the Edinburgh system the conduit was formed of concrete, with cast-iron yokes spaced at intervals of 4 ft. to support the slot beams. The conduit was 19 in. deep by 9 in. wide. The slot was ¾ in. wide. The running rails were of the ordinary girder type bedded in concrete. Fig. 5 shows a cross-section of the track at a yoke. This form of construction is very similar to that employed in forming the tube on a modern electric conduit tramway. At Edinburgh and other places where a shallow conduit is used the supporting pulleys are placed in pits sunk below the general level of the tube. On the Birmingham cable tramway, where the tube is 2 ft. 8 in. deep, pits are not required at the supporting pulleys. This reduces the difficulty of draining the conduit. The yokes in this case are made of steel T-bars spaced 4 ft. apart.

Electric Tramways.—Electricity is now the standard motive power for tramway service, and is applied in three main ways: (1) the overhead or trolley system; (2) the open conduit system; and (3) the surface contact or closed conduit system. (See also TRACTION.)

Overhead Trolley.

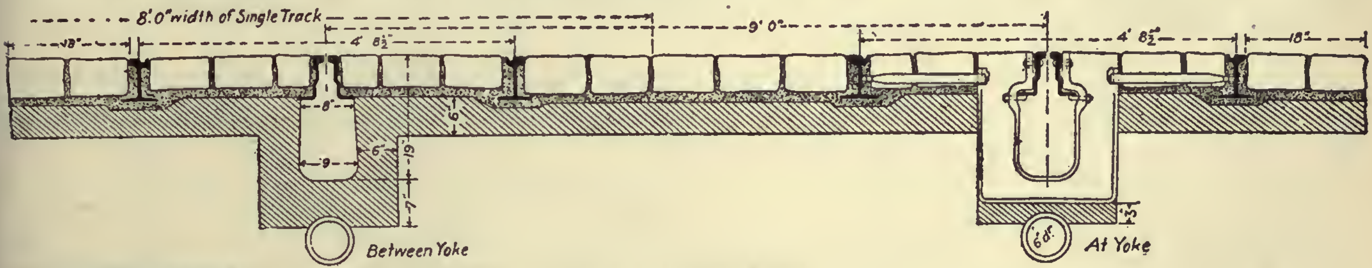
On a tramway worked on the overhead principle current is supplied to the cars by two overhead conductors or wires. Round copper wires varying in size from 0 (0·324 in.) to 0000 (0·40 in.) S.W. gauge are generally used. With feeding points at every mile, the 0 wire is electrically sufficient on most roads, but from a mechanical point of view 00 wire is the smallest it is desirable to erect. Wires having figure 8 or elliptical grooved sections have been employed, and have the advantage of allowing the use of a mechanical clip ear which is clear of the trolley wheel. The ordinary round wire is usually supported by a gun-metal or gun-metal and iron ear grooved to fit the wire, which is soldered or sweated to it. In Great Britain the overhead conductors are required by the board of trade to be divided into half-mile sections. The wires on adjoining sections are connected by section insulators. These consist of gun-metal castings in two parts, insulated from each other. The line wires are clamped to the metal ends. The continuity of the path of the trolley wheel is provided for on the underside of the insulator by fixing a hardwood strip between the ends or by the ribs on the castings with air gaps.

The trolley wires are supported by ears either from span wires which extend across the roadway between two poles or from bracket arms carried on a pole on one side only of the road. The span wires and short bracket suspension wires are also insulated, so that there is double insulation between the conductor and the pole. The overhead conductors are usually hung about 21 ft. above the rails. (For catenary suspensions see TRACTION.) The poles which carry the span wires and the bracket arms are placed not more than 40 yds. apart and are generally placed at the edge of the kerb. They are built up of three sections of steel tubes, one overlapping the other; the joints are shrunk together while hot. A cast-iron case is used to improve the appearance of the pole, and cast-iron collars hide the joints. Standard specifications for poles have been issued by the Engineering Standards Committee.

When permission can be obtained the span wires are sometimes supported by rosettes attached to the walls of the houses on either side of the street. This method has been largely adopted in Germany, and by dispensing with the poles in the roadway it improves the appearance of the street.

Open Conduit.

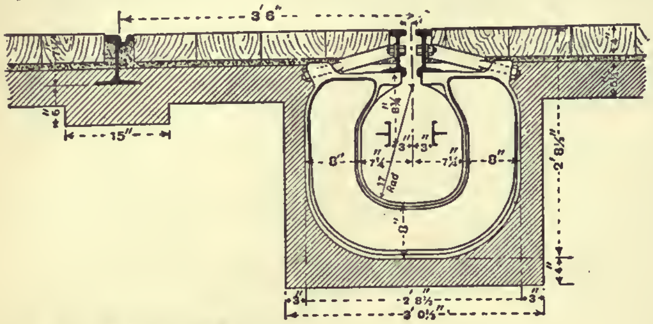
Overhead conductors will not be tolerated in some cities, and to avoid the use of them open conduit and surface contact tramways have been introduced. In the conduit system the conductors are carried in a conduit or tube beneath the surface of the track, and the electric current is picked up by means of a plough carried by the cars. Modern conduit tramways are divided into two kinds: those which have the conduit at the side under one running rail, and those which have it under the centre of the track. The only example of the former to be found in England is at Bournemouth, but it is used at Vienna, Brussels, Paris, Berlin and Budapest. Centre conduit construction has been adopted in London, Nice, Bordeaux, New York, Washington, &c. The advantages of the side slot system are the reduction in the amount of metal



(From T. Arnall's *Permanent Way for Tramways and Street Railways*, by permission of *The Railway Engineer.*)

FIG. 5.—Section Edinburgh Cable Conduit.

in the roadway, less breaking up of the pavement, and slightly cheaper cost of construction. Its chief disadvantage is the difficulty it introduces in connexion with points and crossings. It is also objected that if the side slot is made the same width as the rail groove



(From *The Tramway and Railway World.*)

FIG. 6.—Section of Side Conduit.

it becomes a danger to narrow-tired vehicles. The difficulty in regard to points and crossings is overcome by bringing the slot into the centre of the track at junctions and turn-outs. Fig. 6 shows a section of the side slot track laid at Bournemouth. The width of

FIG. 7.—Section of Centre Conduit (London County Council type).

the slot is 1 in., which is the least width possible. In London ¾ in. was first adopted as the width of the centre slot, but later this was increased to 1 in., so that in this particular there is not much to choose between the two systems. Fig. 7 shows a section of the London County Council track at one of the cast-iron yokes. These are spaced 3 ft. 9 in. apart, every second yoke being now continued out under the running rail which is fastened to it. There is no doubt that the extended yoke greatly increases the strength of the track. The slot beams weigh 60 ℔ per yard. The conductor bars are of mild steel, T-shaped. They weigh 22 ℔ per yard and are supported on insulators at intervals of 15 ft. Each insulator is covered over in the roadway with a cast-iron frame and movable lid. There are two conductor rails—positive and negative—so that the whole circuit is insulated from earth. The conduit or tube is formed of cement concrete. The track between the rails is paved with granite setts in order that there may be no trouble with wood blocks swelling and closing the slot.

American practice in conduit construction has become fairly well standardized (fig. 8). The conduit is oval in shape, its major axis being vertical, and is formed of concrete. An excavation about 30 in. deep and 5 ft. wide is made, and in this are laid cast-iron yokes weighing 410 ℔ each, and spaced 5 ft. apart centre to centre. Every third yoke contains bearings for a hand-hole plate, and weighs about 600 ℔. These yokes surround the conduit proper and are provided with extensions on each side for the attachment of the rails. In the older construction the rails were laid directly upon the iron of the yokes, steel wedges and shims being used under them for the final alinement of the rails. In the more recent construction, on the Third Avenue railroad in New York City, a wooden stringer, 6 in. by 4¾ in. in size, is laid along from yoke to yoke on the bearing surfaces, and the rail laid upon this. The rail is held down on the yoke by means of two bolts at each bearing-point, these bolts having turned-up heads which embrace the foot of the rail. The slot rails, or Z bars forming the two jaws of the ¾ in. slot, are bolted to the upper part of the yokes. The weights of the metal used per linear yard of construction of this type are: castiron, including both types of yokes, 500 ℔; track rails, 214 ℔; slot rails, 116 ℔; conductor rails, 42 ℔; and conduit plate, 16 ℔—nearly 400 ℔ of rolled steel per yard. After the rails, which are of a high girder type, are fastened in place thin plates of sheet steel are bent into the oval holes in the yokes extending from yoke to yoke, and form the inner surface of the completed conduit. Around this is carefully laid a shell, 4 in. thick, of Portland cement concrete. The yokes are furnished with lugs which serve to retain, temporarily, wooden boards forming a mould in which the concrete is rammed. Sectional wooden shapes serve to hold the thin steel lining in place while the concrete is hardening. Around this concrete tube, and on each side of it, to form a basis for the street pavement, is laid a mass of coarser concrete. In each side of the special yokes is placed an insulator of porcelain, protected by a cast-iron shell and carrying a support for the conductor rail, which is of T-shaped steel, weighing 21 ℔ per yard. It is in 30 ft. lengths and is supported every 15 ft. by the insulators, the ends of separate rails being matched at and held by an insulator support. This rail is, of course, bonded with copper bonds. Two such con-

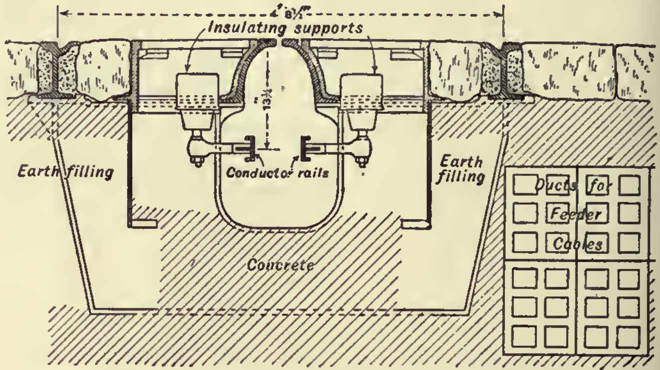

FIG. 8.—Cross-section of Open Conduit Road (American type).

ductor rails are installed in the conduit 6 in. apart, the flat faces corresponding to the upper surface of the T being placed towards each other. Elaborate provisions for drainage and inspection are also provided, depending upon the situation of the tracks and nature of the street. The current is fed to the conductor rails by heavy copper conductors of from 500,000 to 1,000,000 circular mils cross-section, insulated and lead-covered, laid in ducts alongside of or between the two tracks of double-track systems. Connexion is

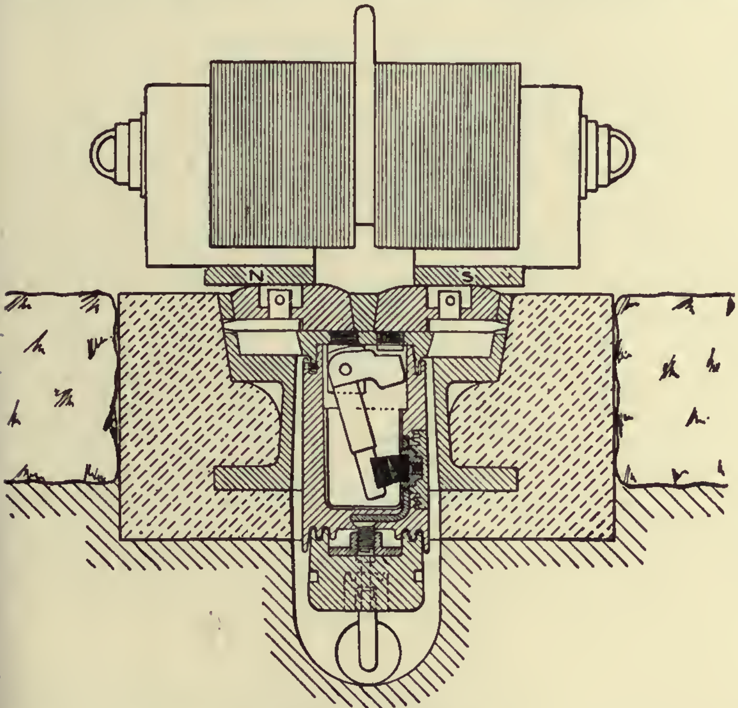
FIG. 9.—Cross-section of Stud, Skates and Magnets. Lorain System.

made between the cars and the conductor rails by means of a "plough," carried by a hard steel plate, which is channelled to receive the insulated wires leading up to the controller on the car. The plough carries two cast-iron rubbing-blocks, which are pressed outward into contact with the conductor rails by springs, the two being, of course, very carefully insulated from each other and from the other metal-work of the plough. It has been found expedient in practice to reverse the polarity of the current used on these conduit roads from time to time, since electrolytic deposits, formed by small leakage currents in the vicinity of insulators, &c., are thus dissolved before they become a source of trouble.

Great difficulty is experienced with all conduits in keeping them clean and free from water. On the London tramways a sump has been formed at intervals of about 60 yds. into which the conduit drains. These sumps are connected with the sewers. The principal objection to the conduit system is its heavy first cost. The tracks alone in London are estimated to cost about £13,000 per mile of single track against about £8000 per mile for a track to be worked on the overhead system.

This high cost of construction has caused considerable attention to be directed by inventors to devising surface contact systems.

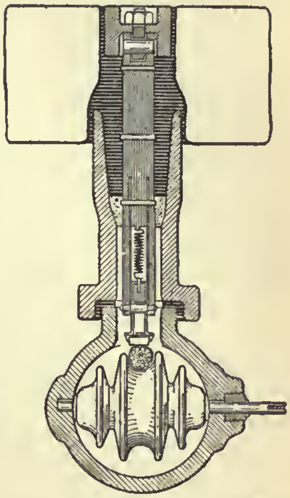
Surface Contact. Many of the designs which have been patented appear excellent in theory, but have been found untrustworthy under working conditions. Among those worked commercially in England are (1) the Lorain system in operation at Wolverhampton; (2) the Dolter system at Torquay, Hastings and Mexborough, and (3) the G.B. system at Lincoln. Of all these systems current is supplied from iron studs laid in the roadway between the rails of the track to a skate carried on the car. The studs are placed 10 ft. to 15 ft. apart and contain a movable switch or contact, which is operated by the influence of a magnet carried under the car. In the Lorain system (fig. 9) connexion is made to the source of power through two carbon contact pieces. The lower carbon contact is carried on a soft iron strip which is connected to the supply cable by means of a flat copper ribbon spring. When the magnet passes from over a stud the iron armature and the lower carbon contact, which has been magnetically attracted, falls vertically, assisted by the copper ribbon spring. In the Dolter system the contact box (fig. 10) contains a bell crank lever with a carbon contact at its lower end. The upper arm of this lever is of soft iron, which is attracted by the magnet carried under the car. When the lever is moved the carbon block at the lower end is brought into contact with the fixed carbon contact in the side of the box which is permanently connected to the supply cable. In the G.B. contact box (fig. 11) contact is made direct to a bare feeder cable carried in a pipe under the boxes. The switch, consisting of a piece of galvanized iron, is suspended freely by means of an insulated phosphor bronze spring. At the lower end of this moving piece a carbon contact piece is attached. When the magnet carried by the car passes over a stud, the moving piece is magnetically attracted to the cable against the pull of the spring. In the Lorain and the Dolter systems the studs are raised slightly above the road surface—which is an objectionable feature—and the current is collected by a skate, suspended under the car, touching the projecting surface. In the G.B. system the stud heads are kept flush with the pavement, and the collector consists of iron links spring suspended. As the collector passes over the box the links are magnetically attracted, and move down, making contact with the stud.



(From J. H. Rider's *Electric Traction*, by permission of Whittaker & Co.)

FIG. 10.—Cross-section of Stud, Skates and Magnets. Dolter System.

In all surface contact systems, short circuiting devices are provided to detect any studs which may remain live after the skate has passed, either by blowing a fuse or by ringing a bell, but it is questionable how much reliance can be placed on their efficiency under all conditions. The collecting skate and magnets carried by the cars on a surface-contact tramway are of considerable weight, and the skate requires renewal at frequent intervals.



(From *The Tramway and Railway World.*)

FIG. 11.—G. B. Stud.

An efficient system of street traction may be defined as one which, while giving a reasonable return on the capital invested, provides the public, without disfigurement of the highway, with a quick and frequent service of comfortable cars.

When tramways were first introduced the surface of the streets was often exceedingly rough. The tramcar running on rails was therefore a great advance in comfort of travelling on the old stage carriage. Horse traction, however, limited the weight of the car and the speed of travelling. The substitution of steam traction for horse traction was a great advance. Higher speeds and quicker acceleration

Advantages of Different Systems. were obtained, and larger and more comfortable cars could be worked. The power, however, was limited, and the locomotives, built as light as possible, were expensive in first cost and maintenance. Cable traction, owing to the heavy first cost of the track, requires a great density of traffic to make it pay. The speed is limited both up and down hill to that of the cable. It has the advantage that it can be safely worked on severe gradients, and once installed the working costs are low.

Electric traction by accumulator cars was tried in Birmingham in 1890 and abandoned after some years of unsatisfactory working. The cars were costly to work and maintain. The storage batteries had to be recharged at frequent intervals, and they rapidly dropped in capacity. There was little reserve of power, and the cells added considerably to the weight of the car.

Those forms of electric traction in which the power is supplied to the cars from an outside source have many advantages. Only the weight of the motors has to be carried. These are efficient over a wide range of speed, accelerate quickly, have a large reserve of power and are clean and silent. The electric conduit and surface contact tramways do not require any disfiguring overhead wires. They have, however, troubles of their own. The construction of the electric conduit is so expensive that its choice must necessarily be limited to large cities. The conductors are easily short-circuited. Gaps in the conductors must be left at the points and crossings. The cost of keeping the conduit clean is considerable. It has the advantage, however, of having both the positive and negative conductors insulated. Surface contact systems require studs or contact boxes to be placed in the road. In most systems these project above the surface of the street. The switches which they contain are hidden away from inspection. A failure of insulation or the sticking of a switch may allow a live stud to be unprotected in the roadway. The weight of the car and consequently the power required to move it is considerably increased by the skate, magnet and battery which have to be carried.

For simplicity of working the overhead system easily comes first. The conductors are out of reach, they can easily be doubly or trebly insulated, and with their insulators are open to inspection. The poles and wiring can be erected without closing or obstructing the street. The supply of power is not interfered with by heavy rain, snow or other climatic causes. Duplicate conductors are used, and repairs can be rapidly executed. The only objection is that of unsightliness, which, however, can be greatly reduced by good design.

The cost of establishing tramways to be worked on the various systems of traction mentioned above has varied considerably. The locality and the amount of street widening have considerable influence on the total. Horse tramways in the larger cities cost in the past about £15,000[1] per track mile complete with horses, cars, &c., tramways worked by steam power about £18,000[2] per track mile including locomotives and cars. The Edinburgh Corporation cable tramways cost £23,316[3] to establish complete with power-house, cars, &c. Of this figure, the cost of the permanent way construction amounted to £14,431.[3] The construction and equipment of the South London conduit tramways cost £25,106[3] per mile of single line; the permanent way, its electrical equipment and the distributing cables cost £15,895[3] per track mile. More recent estimates appear to show that the average cost in London will be between £26,000 and £30,000 per track mile. In Glasgow the total cost of constructing and equipping the electric tramways on the overhead system, including the provision of a power station, cost £19,787[4] per track mile, and at Leeds £13,206. At Manchester, where current is provided by the lighting station, the complete cost works out at £12,498.[5] The cost of the permanent way, cables and electrical equipment per track mile varies from £6575 at Manchester to £9959 at Glasgow. The cost of laying down a surface contact electric tramway is about slightly more than that of constructing and equipping a track with overhead conductors. The cost of the permanent way and its electrical equipment together with the cables at Wolverhampton on the Lorain surface contact principle amounted to £8601 per track mile.

The working expenses of the various systems of traction are largely affected by the age of the tramway, the locality, and, in the case of electric lines, by the cost at which power is obtained. In Birmingham in 1890–1891[6] horse traction cost 9·79d. per car mile, steam traction 10·99d. per mile, cable traction 6·33d. and electric accumulator traction 9·90d. per car mile. Modern electric trolley lines generating their own current work at from 5d. to 6d. per car mile. Where current is purchased the costs vary from 6d. to 7½d. per car mile. The working costs of the London County Council conduit tramways worked on purchased current amounted to 8·02d. per car mile in the year 1905–1906.

Tramway Cars.—The modern tramway car is made up of two distinct parts, the body and the truck. The present type of double ended car with a platform at each end was first used on the American street railways about 1860. The car body was supported directly on axle-boxes through helical steel or rubber springs.

When the early pioneers were experimenting in the United States with electric traction they attached the motor to the car body. This proved unsatisfactory, and resulted in the development of the modern truck. The truck may be described as a carriage or frame supported on the axle-boxes by springs and supporting by another set of springs the car body. The truck carries the motors and in itself resists all the strains of the driving mechanism.

Modern car bodies are mounted either on a single four-wheeled truck, with a fixed or rigid wheel-base, or on two four-wheeled bogies or swivelling trucks. Four-wheeled radial trucks have been tried on several tramways, but they have not proved satisfactory. The wheel-base of the fixed or rigid truck usually varies from 6 to 7 ft. The length of the wheel-base should be determined by the radius of the sharpest curve. To obtain steady running it should be made as long as possible. Two motors are generally fitted on a car.

Of the bogie or swivelling trucks the greater number now in use are of the "maximum traction" type. This truck is used to obtain the greatest tractive effect from two motors when fitted to a car supported on eight wheels. Each bogie is a small four-wheeled truck in itself. It has one pair of its wheels driven by the single motor and of the standard size—about 30 in.—while the guiding or "pony" wheels are of small diameter. The weight of the car body is supported eccentrically on the truck, so that about 70% to 80% is available for adhesion under the driving-wheels. While this form of truck has many merits, it also has many disadvantages. The small wheels easily leave the rails, while the adhesion of the driving-wheels compared with a four-wheeled car is considerably reduced. Quick acceleration is difficult, and on a greasy rail much energy is lost in slipping. The use of equal-wheeled bogies with a motor on every axle gets over the difficulty of the loss of adhesion but at a greatly increased cost. The current consumption is increased, the first cost is greater, and there are four instead of two motors to be maintained. Steel-tired wheels have largely replaced the cast-iron chilled wheel for many years used on tramcars.

While the various forms of trucks are common both to British and American practice, car body construction differs in many points. The single-deck car is universal outside the United Kingdom, where, although many single-deck cars are worked, the greater number are of the double-deck type. It is claimed that with small single-deck cars a quicker service can be maintained, as they are easier to load and unload and generally handier. On the other hand, the double-deck car seats more than double the number of passengers, requires the same number of men to work it, and takes but little more power to drive it. Experience has proved that the 58-passenger—28 inside and 30 outside—double-deck car mounted on a four-wheeled truck is the type of rolling stock most suitable for British conditions. For heavy rush traffic or long distance travel the larger bogie cars are convenient. They are, however, slow to start and stop, and a 72-passenger car is too much for one conductor to work efficiently. Another difference is due to the width of the cars. In the United States car bodies vary from 8 ft. to 9 ft. 6 in. in width. In Great Britain the width is limited by the Tramways Act of 1870 to 11 in. beyond the outer edge of the wheels, which, on the standard gauge, allows the maximum width to be 6 ft. 10 in. This limit has governed the arrangement of the seating in the cars. Inside, the ordinary side seat is almost invariably adopted. Cross seats have been used, but they leave a very narrow gangway—a great disadvantage at times of overcrowding. On the top deck, where the available width is greater and standing is never permitted, cross seats are universally fitted.

On the old horse cars a straight type of stairway was used. The reserved stairway, brought in about 1902, gave greater protection from accident and increased the seating accommodation on the top deck. It had, however, two great disadvantages. The stairway shut out the motorman's view on the left-hand side, and the stream of passengers descending met the stream of passengers leaving the inside of the car, causing delay. The reversed type of stairway has now been abandoned and the straight type, well protected by railings, is usually fitted.

In addition to the ordinary single-deck and double-deck types of cars which are in general use many other designs are to be found. Single-deck open cars of the "toast-rack" type with transverse seats are popular on many holiday lines. They have the advantage of being quickly filled and emptied. Centre vestibule cars are now seldom seen. It is inconvenient not to have the conductor at the back of the car where he can look out for passengers, and, if necessary, "nurse" the trolley. There is also danger of a passenger being struck by the axle-boxes of the rear bogie truck when leaving the car. The Californian type of car body, with the central part closed in and one or two double-sided transverse seats at each end, has been used on routes where low bridges do not allow of the use of double-deck cars. The carrying capacity of this type in wet weather when the exposed seats cannot be used is small. A demi or one-man car has been worked in some towns. It saves the wages of one man, but the average speed of the service is reduced. Top deck covers have in recent years been largely fitted. Their use practically doubles the covered seating capacity of the car and provides accommodation for smokers, a difficult matter on a single-deck car.

In Great Britain the board of trade requires all cars to be fitted with an efficient form of lifeguard. The gate and tray pattern, in which anything striking the vertical gate drops the tray, is that principally employed. In addition to the ordinary hand-brake which operates shoes on all the wheels, and the electric reverse switch, a large number of cars are fitted with some form of electric brake (see TRACTION).

Legislative Conditions in Great Britain.—The first tramways constructed in Great Britain were promoted by private enterprise under powers conferred by private acts of parliament. Considerable opposition was offered to pioneer schemes, but after a few private acts had been passed, parliament, in 1870, passed a general act providing for the laying of rails upon roads, and specifying the procedure for tramway promotion and the main relations between tramway undertakers and local authorities. The Tramways Act 1870, which is still in force, enabled promoters to apply to the board of trade for a provisional order which, when confirmed by parliament, possesses all the force of an act of

[5] Ibid., year ended March 31, 1905.
[6] See *Tramways: Their Construction and Working*, by D. K. Clarke.

parliament. The procedure is therefore simpler and cheaper than private bill procedure. Under this act promoters are obliged to obtain, as a condition precedent to making application for a provisional order, the consent of local authorities in whose areas the proposed tramways are to run. This provision is referred to as the "veto clause." Where a line is laid in two or more districts and two-thirds of the line are in districts where the local authorities do consent, the board of trade may dispense with the consent of the remainder. When procedure by private bill is adopted a similar "veto" provision is made by Standing Order 22, which requires the consent of the local authority (and of the road authority where there is one distinct from the local authority) before the bill goes to first reading; in this case also the consent of authorities for two-thirds of a continuous line are deemed sufficient. The powers granted under the Tramways Act are in perpetuity, subject to the right of the local authorities (under the 43rd section) to purchase, at the end of twenty-one years or each septennial period following (or within three months after the promoters have discontinued working the tramway or have become insolvent), so much of the undertaking as lies within their areas, on paying the then value of the properties suitable to and used for the undertaking, exclusive of any allowance for past or future profits or compensation for compulsory sale or any other consideration whatsoever, such value to be determined by an arbitrator appointed by the board of trade. Another part of the arrangement specified between the local authorities and the undertakers is that the undertakers shall pave the tramway track between the outer rails and for 18 in. beyond each outer rail. Mr G. F. Shaw-Lefevre (afterwards Lord Eversley), when introducing the bill in 1870, said that it "would give powers to the local authorities to construct tramways, but not, of course, to work them." The idea apparently was that local authorities should retain full control of the roads by constructing the tramways, and would make arrangements with lessees on terms which would secure reasonable fares and other conditions for the benefit of the travelling public. It was not until 1896 that parliament permitted local authorities to work tramways as well as own them, except in cases where lessees could not be obtained. The precedents for municipal working were created by private acts at a time when public opinion was in favour of that policy; and after the first few bills for municipal tramway working had been successful, other municipalities found practically no difficulty in obtaining the desired powers, although parliament had never adequately discussed, as a specific reform, the departure from the principle laid down by Mr Shaw-Lefevre in 1870. The conditions in fact proved more favourable to municipal than company promoters, since the local authorities, as soon as they aspired to work tramways as well as own them, used the power of veto against the proposals of companies.

The situation entered a more acute phase when electric traction was introduced on tramways. The Tramways Act provides, by section 34, that all carriages shall be moved by the power prescribed by the special acts or provisional order, and where no such power is prescribed, by animal power only. The mechanical power used must be by consent of the board of trade, and subject to board of trade regulations. Owing to the capital expenditure involved in electric traction, undertakings nearing the end of their twenty-one years' tenure found that it was not commercially feasible to carry out the change without an extension of tenure. The local authorities were reluctant to grant that extension, and they were also reluctant to give permission for the promotion of new lines.

The difficulties of the altered conditions created by the advent of electric traction were met to some extent by the Light Railways Act 1896. This act contains no definition of a light railway, and it has been used largely for electric tramway purposes. Lord Morley, when piloting the bill through the Lords, said that "light railway" includes "not merely all tramways but any railway which the board of trade thinks may justly be brought within the scope." It certainly includes tramways in towns, and it might include large trunk lines throughout the country." Accordingly it has been used for the construction of many miles of tram lines on the public streets and also in some cases for extensions where the track leaves the public road, and is laid on land purchased for the purpose. These tracks are generally constructed with grooved girder rails, having a wide groove and a high check, so that the shallow flanged tramcar wheels can run on them with safety at high speeds. The rails are laid on cross sleepers and ballasted in the ordinary railway fashion. Fencing is erected, but level-crossing gates are often omitted, and cattle guards only are used to prevent animals straying on the track. These sleeper tracks on private ground are cheap to maintain if well constructed in the first instance. Speeds of 20 to 25 m. an hour have been sanctioned on electric lines of this character, worked by ordinary tramway rolling stock. There is no purchase clause in the Light Railways Act, but arrangements for purchase of the undertaking were usually made with the local authorities and the terms embodied in the order. The act contains no veto clause, section 7 stating that the commissioners are to "satisfy themselves that all reasonable steps have been taken for consulting the local authorities, including road authorities, through whose areas the railway is intended to pass, and the owners and occupiers of the land it is proposed to take." The Light Railway Commissioners, however, have interpreted the act in the spirit of the Tramways Act, so that for all practical purposes the veto remains. The new act differed from the Tramways Act in providing for the compulsory purchase of land under the Lands Clauses Acts—the Tramways Act expressly stating that the promoters should not be empowered to acquire land otherwise than by agreement. The board of trade has held that the act does not apply to tramways wholly within one borough. County, borough and district councils as well as individuals and companies are empowered to promote and work light railways.

The passing of the act gave a great impetus to the construction of tramways worked by electric traction. But owing to the practical retention of the veto, there was not so much progress as was anticipated. Another cause of restriction was section 9, sub-section 3, which provides that if the board of trade considers that "by reason of the magnitude of the proposed undertaking, or of the effect thereof on the undertaking of any railway company existing at the time, or for any other special reason relating to the undertaking, the proposals of the promoters ought to be submitted to parliament," they should not confirm the order. In many cases railway companies, by pleading the competitive influence of proposed tramways promoted under the Light Railways Act, were able to force the promoters to apply to parliament or to drop the scheme. The latter alternative was frequently adopted, owing to the costs of parliamentary procedure being too heavy for the undertaking.

Commercial Results.—Interest in the commercial results of tramway enterprise is practically limited to electric traction, since other forms of traction have been almost entirely superseded owing to their economical inferiority. The main advantages of electric traction over horse traction lie in the higher speed, greater carrying capacity of cars, and the saving in power over a system in which only a small proportion of the power source is available at one time. Steam, compressed air and gas traction possess the disadvantages that each car has to carry the dead weight of power-producing machinery capable of maintaining speed up to the maximum grade. Cable traction has the disadvantages that the speed of the cars is limited by the speed of the cable, that the range and complexity of the system are restricted, and that construction is expensive. The electric system, in which power is generated at a central source and distributed to cars which take power in proportion to the work being done, possesses a higher degree of flexibility, convenience and economy than any other system. Electric tramways in Great Britain are mostly equipped on the overhead trolley system, though the conduit and the surface contact systems have been installed in a few instances. Roughly the capital expenditure required for the three systems is in proportion of 2, 1½ and 1, and both the conduit and the surface contact systems are more costly to maintain than the overhead system. A fourth system of electric traction, in which the cars are fitted with storage batteries charged at intervals, has been tried frequently and as frequently abandoned. The great weight of the batteries, the serious initial cost and high rate of deterioration prevented the attainment of financial success.

The earliest development of electric road traction on a large scale took place in America and on the continent of Europe, and the estimates for British tramways were therefore prepared from American and continental results. The following figures summarize a number of estimates made at this period; the first table gives the figures for capital cost, and the second for operating expenses. The receipts were estimated at 10d per car mile.

	Capital cost per mile of single track.
	£
Permanent way, including bonding	5050
Overhead equipment	750
Feeder cables	400
Cars at £700 each	2100
Car sheds, sundries and contingencies	1200
Total	£9500

Operating expenses per car mile.

Electrical energy	1·50d.
Wages of drivers and conductors	1·10
Car shed expenses, wages and stores	0·55
General expenses	0·90
Repairs and maintenance	1·25
Total	5·30d.

The estimates gave reason to expect that electric traction would mean cheaper fares and more frequent services at a higher speed, resulting in a considerable increase in traffic receipts per mile and a substantial reduction of working expenses. The result of pioneer undertakings in South Staffordshire, Bristol and Coventry supported this expectation. Later experience, however, showed that the estimates were too optimistic. Taking the actual figures realized for the undertakings included in the above tables, the capital expenditure per mile of single track was £12,000 and the working expenses per car mile 6·3d. The expectations as to gross revenue have been generally realized, but the increase in capital expenditure and working expenses over the estimates is typical of electric tramways in Great Britain. In the matter of wear and tear the estimates have also been too low. The reasons for the larger capital expenditure are (1) superior track construction, (2) more elaborate overhead equipment, (3) use of larger cars, (4) higher cost of road paving and other improvements imposed upon tramway undertakings.

According to the official returns of tramways and light railways for the year 1905–1906, there were 312 tramway undertakings in the United Kingdom, and 175 of these belonged to local authorities. Out of the total of 1491 m. of line owned by local authorities, 1276 m. are worked by these authorities themselves, and the remaining 215 m. by leasing companies. Local authorities working as well as owning their tramways made a net profit of £2,529,752, applying £663,336 to the reduction of tramway debt and £205,981 to the relief of rates, while carrying £623,617 to reserve and renewal funds. The following table summarizes the amounts expended by local authorities on electric traction:—

Year.	Municipalities.	£
1900	11	1,169,429
1901	18	2,748,873
1902	47	10,519,543
1903	61	14,644,126
1904	92	21,295,771
1905	115	27,876,320
1906	131	31,147,824
1907	131	35,965,920

The corresponding table for electric traction companies (including electric railways), detailing the amounts and proportions of ordinary preference and loan and debenture capital, is as follows:—

Year.	Number of undertakings.	Ordinary capital.	Per cent. to total.	Preference capital.	Per cent. to total.	Loan and Debenture capital.	Per cent. to total.	Total.
		£		£		£		£
1896	17	5,041,375	83	412,776	7	630,521	10	6,084,672
1897	30	6,584,147	88	124,850	2	727,176	10	7,436,173
1898–1899	51	9,793,234	68	1,640,780	11	2,972,126	21	14,406,140
1899–1900	66	11,770,777	60	3,834,761	20	4,033,992	20	19,639,530

The financial results achieved by electric traction companies are summarized in the next table:—

Year.	Number of companies.	Aggregate capital.	Average ordinary capital.	Average preference capital.	Average loan and debenture capital.	Total average.
		£	%	%	%	%
1899–1900	24	9,056,332	3·87	5·56	4·64	4·37
1900–1901	37	15,021,137	4·27	5·53	4·57	4·65
1901–1902	62	28,322,117	4·07	4·44	4·53	4·29
1903	64	35,479,296	4·31	5·11	4·47	4·57
1904	77	48,789,525	4·13	4·81	4·53	4·41
1905	90	61,273,986	3·79	4·92	4·39	4·33
1906	117	77,202,373	3·47	4·81	4·18	4·13
1907	118	99,315,028	2·87	4·25	4·38	3·78 [1]

The total expenditure on tramways and light railways (omitting railways—main, branch and suburban) was £15,195,993 in 1896 and £58,177,832 in 1906.

One effect of the increased cost of expenditure per mile of track is to discourage extensions of rural and inter-urban lines where the traffic is not heavy. Proposals have been made to adopt the "rail-less trolley" (used in some places on the continent of Europe) for such extensions. In this system the cars run on ordinary wheels and take power from overhead trolley wires. But so far no such arrangement has been put into practice in Great Britain, and outlying districts are generally dealt with by petrol or steam motor vehicles, running as feeders to the tramways and railways. The future commercial development of tramways lies more in the economics in working than in growth of track mileage. Owing to the enormous volume of traffic a very slight alteration in one of the items of expense or revenue produces a large result in the aggregate. The addition of ½d. per car mile to revenue or a corresponding reduction in expenses would, on the 240 millions of car miles run in 1905–1906, result in a gain of about £500,000 per annum, which is equal to nearly 1 % on the entire capital expenditure in respect of tramways and light railways. The tables given above show that the yield upon the capital invested in electric traction is not high. The effect of increased capital expenditure has been accentuated by reductions in fares. In 1886 the average fare per passenger was 1·61d. and in 1896 it was 1·31d., falling in 1906 as low as 1·10d. Some systems carry passengers over 2½ m. for one penny, workmen being carried twice the distance for the same sum. Halfpenny fares are represented as a boon to the working man, but they have been abandoned as a failure after several years' trial on several systems, and in Glasgow it is found that halfpenny fares contribute only 20·4 % of the early morning traffic, while the penny fare contributes 72·3 % of that traffic. The general manager of the Birmingham Corporation tramways reported against halfpenny fares on the basis of his experience as general manager of the London County Council tramways that all the halfpenny passengers there are carried at a loss. The adjustment of fares and stages to their proper value is a question now carefully studied by tramway managers along with many problems of economy in working. The close adjustment of the service to the fluctuations in traffic is one source of economy which is being more seriously considered. Many systems have adopted top covers to cars in order to carry more passengers during wet weather. The adoption of these covers is not popular in fine weather; it adds to the weight and wind-resistance of the cars, thus increasing current consumption, and it adds to the cost of construction and maintenance. Economy in electrical energy is, in its broader aspects, secured by purchasing current from an outside source in preference to generating it at a special station. The average cost per unit of electricity for all tramway undertakings in the United Kingdom is 1·06d., but one tramway company which purchases its energy from a large power company pays only 0·85d. per unit. In its narrower aspects economy in current may be secured by reducing waste car mileage—that is to say, eliminating the running of cars at times and places where they are not required for an adequate service. Saving may also be effected by supervision of the driving of the cars, since the difference of as much as 20 % has been noted between different drivers. One tramway manager secured substantial improvement by merely marking on the trolley standards the position which the controller handle should occupy in passing each point. The limitation of stops is another source of economy, the average cost per stop on a system having been found to be 0·17 d. A slight increase in the maximum speed of tramcars would

[1] Average reduced owing to inclusion of Metropolitan and Metropolitan District railways' capital.

also improve the net results by reducing the proportion of standing charges (wages, &c.) to the traffic capacity of the system without making the cost of maintenance or current more than slightly greater. A 15 % increase in average speed means a saving of ¼d. per car mile. The development of parcels traffic is a source of revenue, and additional receipts can be earned by the hiring-out of cars for picnics and other special purposes. An important point is the proper selection of the size of car. A small four-wheeled car is suitable to continual traffic of comparatively small volume, but when the traffic is heavy cars of larger capacity are advisable. A serious burden on tramways is the cost of insurance against accidents, although the number of serious accidents on electric tramways is exceedingly small in proportion to the number of passengers carried, the ratio of tramway accidents of all kinds being about one accident to every 15,000 passengers.

There are many adjoining towns having separate tramway undertakings which do not provide intercommunication. Experience has shown that a break of tramway facilities reduces the receipts by 20 to 50 % on the lines which have been severed; and the terminal half-mile, except in populous districts, is the least remunerative section of a tramway route.

Statistics.—Each year the British board of trade issues a return of street and road tramways and light railways authorized by act or order, showing the amount of capital authorized, paid up and expended; the length of line authorized and the length open for public traffic; the gross receipts, working expenditures, net receipts and appropriation of net receipts; the number of passengers conveyed; the number of miles run by cars and the quantity of electrical energy used; together with the number of horses, engines and cars in use. The return published in January 1909 deals with the figures for local authorities up to the 31st of March 1908 and for companies up to the 31st of December 1907. The following comparative table summarizes the most important general figures for the United Kingdom provided by this official return:—

	Years ended June 30.				Year ending Dec. 31 (companies) and March 31 (local authorities).
	1878.	1886.	1898.	1902.	1907–1908
Total capital authorized	£6,586,111	£17,640,488	£24,435,427	£51,677,471	£91,305,439
Total capital expended	£4,207,350	£12,573,041	£16,492,869	£31,562,267	£68,199,918
Length of route open (miles)	269	865	1,064	1,484	2,464
Number of horses	9,222	24,535	38,777	24,120	5,288
Number of locomotive engines	14	452	589	388	64
Number of cars	1,124	3,440	5,335	7,752	10,908
Total number of passengers carried	146,001,223	384,157,524	858,485,524	1,394,452,983	2,625,532,895
Quantity of electrical energy used, B.O.T. units	—	—	—	—	431,969,119
Gross receipts	£1,099,271	£2,630,338	£4,560,126	£6,679,291	£12,439,625
Working expenditure	£868,315	£2,021,556	£3,507,895	£4,817,873	£7,792,663
Net receipts	£230,956	£608,782	£1,052,231	£1,861,418	£4,646,962

The total figures at the date of the return are summarized in the following table, which is accompanied by one showing the lengths of line worked by various methods of traction:—

	Capital expenditure on lines and works open for traffic.	Total expenditure on capital account.	Length open for traffic.						No. of undertakings.
			Double.		Single.		Total.		
	£	£	M.	Ch.	M.	Ch.	M.	Ch.	
Tramways and light railways belonging to local authorities	32,978,579	44,920,317	1113	77	505	77	1619	74	177
Tramways and light railways belonging to companies and private individuals	18,641,279 [1]	23,279,601	408	58	435	46	844	24	128
Total United Kingdom	51,619,858	68,199,918	1522	55	941	43	2464	18	305

Table showing lengths worked by various methods of traction:—

Method of traction.	England and Scotland.				Ireland.		Total.	
	M.	Ch.	M.	Ch.	M.	Ch.	M.	Ch.
Electric	1922	66	235	35	127	69	2286	10
Steam	22	67	—	—	29	45	52	32
Cable	4	49	22	72	—	—	27	41
Gas motors	4	2	—	—	—	—	4	2
Horse	82	60	4	28	7	5	94	13
Total.	2037	4	262	55	164	39	2461	18

[1] These figures include cost of buildings and equipment in respect of certain local authorities' lines worked in conjunction with other lines.

The following table gives a few totals, ratios, and percentages for the last two years of what may be called a period of electric traction, in comparison with a typical "steam" period (*i.e.* a period in which the use of steam power in tramways was at its maximum) and a typical " horse " period:—

	Electric period, 1907–1908.	Steam period, 1896.	Horse period, 1879.
Length of route open	2,464·22	1009	321·27
Total number of passengers carried	2,625,532,895	759,466,047	150,881,515
Percentage of net receipts to total capital outlay	6·81	6·88	3·97
Percentage of working expenditure to gross receipts	62·64	74·79	83·81
Passengers carried per mile of route open	1,065,462	752,691	469,641
Average fare per passenger	1·09d.	1·61d.	1·84d.

From the above figures it will be noticed that the capital cost per mile has increased as a result of the adoption of electric traction, while at the same time the percentage of the return on the capital has been reduced notwithstanding that the rate of working expenditure has fallen and the number of passengers carried per mile has increased, the fares charged having been disproportionately reduced.
(E. GA.)

TRANCE (through the French, from Lat. *transitus*, from *transire*, to cross, pass over), a term used very loosely in popular speech to denote any kind of sleeplike state that seems to present obvious differences from normal sleep; in medical and scientific literature the meaning is but little better defined. In its original usage the word no doubt implied that the soul of the entranced person was temporarily withdrawn or passed away from the body, in accordance with the belief almost universally held by uncultured peoples in the possibility of such withdrawal. But the word is now commonly applied to a variety of sleeplike states without the implication of this theory; ordinary sleep-walking, extreme cases of melancholic lethargy and of anergic stupor, the deeper stages of hypnosis (see HYPNOTISM), the cataleptic state, the ecstasy of religious enthusiasts, the self-induced dream-like condition of the medicine-men, wizards or priests of many savage and barbarous peoples, and the abnormal state into which many of the mediums of modern spiritualistic seances seem to fall almost at will; all these are commonly spoken of as trance, or trance-like, states. There are no well-marked and characteristic physical symptoms of the trance state, though in many cases the pulse and respiration are slowed, and the reflexes diminished or abolished. The common feature which more than any other determines the application of the name seems to be a relative or complete temporary indifference to impressions made on the sense-organs, while yet the entranced person gives evidence in one way or another, either by the expression of his features, his attitudes and movements, his speech, or by subsequent relation of his experiences, that his condition is not one of simple quiescence or arrest of mental life, such as characterizes the state of normal deep sleep and the coma produced by defective cerebral circulation by toxic substances in the blood or by mechanical violence done to the brain.

If we refuse the name trance to ordinary sleep-walking, to normal dreaming, to catalepsy, to the hypnotic state and to stupor, there remain two different states that seem to have equal claims to the name; these may be called the ecstatic trance and the trance of mediumship respectively.

The ecstatic trance is usually characterized by an outward appearance of rapt, generally joyful, contemplation; the subject seems to lose touch for the time being with the world of things and persons about him, owing to the extreme concentration of his attention upon some image or train of imagery, which in most cases seems to assume an hallucinatory character (see HALLUCINATION). In most cases, though not in all, the subject remembers in returning to his normal state the nature of his ecstatic vision or other experience, of which a curiously frequent character is the radiance or sense of brilliant luminosity.

In the mediumistic trance the subject generally seems to fall into a profound sleep and to retain, on returning to his normal condition, no memory of any experience during the period of the trance. But in spite of the seeming unconsciousness of the subject, his movements, generally of speech or writing, express, either spontaneously or in response to verbal interrogation, intelligence and sometimes even great intellectual and emotional activity. In many cases the parts of the body not directly concerned in these expressions remain in a completely lethargic condition, the eyes being closed, the muscles of neck, trunk and limbs relaxed, and the breathing stertorous.

Trances of these two types seem to have occurred sporadically (occasionally almost epidemically) amongst almost all peoples in all ages. And everywhere popular thought has interpreted them in the same ways. In the ecstatic trance the soul is held to have transcended the bounds of space or time, and to have enjoyed a vision of some earthly event distant in space or time, or of some supernatural sphere or being. The mediumistic trance, on the other hand, popular thought interprets as due to the withdrawal of the soul from the body and the taking of its place, the taking possession of the body, by some other soul or spirit; for not infrequently the speech or writing produced by the organs of the entranced subject seems to be, or actually claims to be, the expression of a personality quite other than that of the sleeper. It is noteworthy that in almost all past ages the possessing spirit has been regarded in the great majority of cases as an evil and non-human spirit; whereas in modern times the possessing spirit has usually been regarded as, and often claims to be, the soul or spirit of some deceased human being. Modern science, in accordance with its materialistic and positive tendencies, has rejected these popular interpretations. It inclines to see in the ecstatic trance a case of hallucination induced by prolonged and intense occupation with some emotionally exciting idea, the whole mind becoming so concentrated upon some image in which the idea is bodied forth as to bring all other mental functions into abeyance. The mediumistic trance it regards as a state similar to deep hypnosis, and seeks to explain it by the application of the notion of cerebral or mental dissociation in one or other of its many current forms; this assimilation finds strong support in the many points of resemblance between the deeper stages of hypnosis and the mediumistic trance, and in the fact that the artificially and deliberately induced state may be connected with the spontaneously occurring trance state by a series of states which form an insensible gradation between them. A striking feature of the mediumistic trance is the frequent occurrence of "automatic" speech and writing; and this feature especially may be regarded as warranting the application of the theory of mental dissociation for its explanation, for such automatic speech and writing are occasionally produced by a considerable number of apparently healthy persons while in a waking condition which presents little or no other symptom of abnormality. In these cases the subject hears his own words, or sees the movement of his hand and his own hand writing, as he hears or sees those of another person, having no sense of initiating or controlling the movements and no anticipatory awareness of the thoughts expressed by the movements. When, as in the majority of cases, such movements merely give fragmentary expression to ideas or facts that have been assimilated by the subject at some earlier date, though perhaps seemingly completely forgotten by him, the theory of mental dissociation affords a plausible and moderately satisfactory explanation of the movements; it regards them as due to the control of ideas or memories which somehow have become detached or loosened from the main system of ideas and tendencies that make up the normal personality, and which operate in more or less complete detachment; and the application of the theory is in many cases further justified by the fact that the "dissociated" ideas and memories seem in some cases to become taken up again by, or reincorporated with, the normal personality.

But in recent years a new interest has been given to the study of the mediumistic trance by careful investigations (made with a competence that commands respect) which tend to re-establish the old savage theory of possession, just when it seemed to have become merely an anthropological curiosity. These investigations have been conducted for the most part by members of the Society for Psychical Research, and their most striking results have been obtained by the prolonged study of the automatic speech and writing of the American medium, Mrs Piper. In this case the medium passes into a trance state apparently at will, and during the trance the organs of speech or the hand usually express what purport to be messages from the spirits of deceased relatives or friends of those who are present. A number of competent and highly critical observers have arrived at the conviction that these messages often comprise statements of facts that could not have come to the knowledge of the medium in any normal fashion; and those who are reluctant to accept the hypothesis of "possession" find that they can reject it only at the cost of assuming the operation of telepathy (*q.v.*) in an astonishing and unparalleled fashion. During 1907–1908 the investigation was directed to the obtaining of communications which should not be explicable by the most extended use of the hypothesis of telepathic communication from the minds of living persons. The plan adopted was to seek for "cross-correspondences" between the communications of the Piper "controls" and the automatic writings of several other persons which claimed to be directed by the same disembodied spirits; *i.e.* it was sought to find in the automatic writings of two or more individuals passages each of which in itself would be fragmentary and unintelligible, but which, taken in connexion with similar fragments contemporaneously produced by another and distant writer, should form a significant whole; for it is argued that such passages would constitute irrefutable evidence of the operation of a third intelligence or personality distinct from that of either medium. The results published up to 1909 seem to show that this attempt met with striking success; and they constitute a body of evidence in favour of the hypothesis of possession which no impartial and unprejudiced mind can lightly set aside. Nevertheless, so long as it is possible to believe, as so many of the most competent workers in this field believe, that dissociated fragments of a personality may become synthesized to form a secondary and as it were parasitic personality capable of assuming temporary control of the organs of expression, and so long as we can set no limits to the scope of telepathic communication between embodied minds, it would seem wellnigh impossible, even by the aid of this novel and ingenious plan of investigation, to achieve completely convincing evidence in favour of the hypothesis of "possession."

TRANENT, a police burgh of Haddingtonshire, Scotland. Pop. (1901), 2584. It lies $9\frac{1}{2}$ m. E. of Edinburgh by road and 1 m. S.E. of Prestonpans station on the North British railway. The town possesses the oldest coal-mining charter (1202–1218) in Great Britain, and the mines and quarries in the neighbourhood provide the staple industry. A fragment of a parish church, said to have been built in the 11th century, still stands. Of the palace of the Setons which stood in the parish there are no remains. It was demolished towards the close of the 18th century and a modern mansion was erected on its site.

In the neighbouring village of Ormiston, in 1885, a granite obelisk was erected in memory of Robert Moffat (1795–1883), a native, the South African missionary and father-in-law of Livingstone. At Ormiston Hall, a seat of the marquess of Linlithgow, there is a yew tree, beneath which the reformer George Wishart (1513–1546) used to preach. Hard by is the village of Pencaitland, divided into an eastern and a western portion by the Tyne. The parish church in Easter Pencaitland probably dates from the 13th century. The aisle may belong to the original building, but the rest is of the 16th century, excepting the small belfry of the 17th century. The old house of Pencaitland stands in the grounds of Winton Castle, which was erected by the 3rd earl of Winton in 1620 but forfeited by the 5th earl, who was involved in the Jacobite rising of 1715. Five miles south-east of Tranent is the village of Salton (or Saltown), where Gilbert Burnet, afterwards bishop of Salisbury, had his first charge (1665). At his death he bequeathed the parish 20,000 marks for the clothing and educating of poor children. He was tutor to Andrew Fletcher, who was born at Salton in 1655 and buried there in 1716. At Fletcher's instigation James Meikle, a neighbouring millwright, went to Holland to learn the construction of the iron-work of barley mills, and the mill which he erected at Salton after his return not only gave Salton barley a strong hold on the market, but was also for forty years the only mill of its kind in the British Isles. Meikle's son Andrew (1719–1811), inventor of the threshing machine, carried on his trade of millwright at Houston Mill near Dunbar. Andrew Fletcher, also of Salton (1692–1766), nephew of the elder Andrew, became lord justice clerk in 1735 under the style of Lord Milton. By his mother's energy the art of weaving and dressing holland linen was introduced into the village. She travelled in Holland with two skilled mechanics who contrived to learn the secrets of the craft. The British Linen Company laid down their first bleachfield at Salton under Lord Milton's patronage. Salton also lays claim to having been the birthplace of the poet William Dunbar.

TRANI, a seaport and episcopal see of Apulia, Italy, on the Adriatic, in the province of Bari, and 26 m. by rail W.N.W. of that town, 23 ft. above sea-level. Pop. (1901), 34,688. Trani has lost its old walls and bastions, but the 13th-century Gothic citadel is used as a prison. Some of the streets remain much as they were in the medieval period, and many of the houses display more or less of Norman decoration. The cathedral (dedicated to St Nichòlas the Pilgrim, a Greek assassinated at Trani in 1094 and canonized by Urban II.), on a raised open site near the sea, was consecrated, before its completion, in 1143; it is a basilica with three apses, a large crypt and a lofty tower, the latter erected in 1230–1239 by the architect whose name appears on the ambo in the cathedral of Bitonto, Nicolaus Sacerdos. It has an arch under it, being supported partly on the side wall of the church, and partly on a massive pillar. The arches of the Romanesque portal are beautifully ornamented, in a manner suggestive of Arab influence; the bronze doors, executed by Barisanus of Trani in 1175, rank among the best of their period in southern Italy. The capitals of the pillars in the crypt are fine examples of the Romanesque. The interior of the cathedral has been barbarously modernized, but the crypt is fine. Near the harbour is the Gothic palace of the doges of Venice, which is now used as a seminary. The church of the Ognissanti has a Romanesque relief of the Annunciation over the door. S. Giacomo and S. Francesco also have Romanesque façades and the latter and S. Andrea have "Byzantine" domes. The vicinity of Trani produces an excellent wine (Moscato di Trani); and its figs, oil, almonds and grain are also profitable articles of trade.

Trani is the *Turenum* of the itineraries. It first became a flourishing place under the Normans and during the crusades, but attained the acme of its prosperity as a seat of trade with the East under the Angevin princes. The harbour, however, has lost its importance.

TRANQUEBAR, a town of British India, in the Tanjore district of Madras, on the sea-coast, 18 m. N. of Negapatam. Pop. (1901), 13,142. A Danish factory was opened here as early as 1620. It was taken by the British in 1801, but restored in 1814, and finally purchased, with the other Danish settlements in India, in 1845. In Danish times Tranquebar was a busy port, but it lost its importance when the railway was opened to Negapatam. It was the first settlement of Protestant missionaries in India, founded by Ziegenbalg and Plutschau (Lutherans) in 1706; and there is still a Lutheran mission high school and mission press.

TRANSBAIKALIA (sometimes also known as *Dauria*), a province of Eastern Siberia, lying E. of Lake Baikal, with the government of Irkutsk on the N.W. and N., the provinces of Amur and Manchuria on the E. and Mongolia on the S. Its area (232,846 sq. m.) is nearly as large as that of Austria-Hungary, but its population does not much exceed half a million.

Transbaikalia forms an intermediate link between Siberia, Mongolia and the northern Pacific littoral. The Yablonoi Mountains, which run north-east from the sources of the Kerulen to the bend of the Olekma in 56° N., divide the province into two quite distinct parts; to the west, the upper terrace of the high east Asian plateau, continued from the upper Selenga and the Yenisei (4000 to 5000 ft. high) towards the plateau of the Vitim (3500 to 4000 ft.); and to the east the lower terrace of the same plateau (2800 ft.), forming a continuation of the eastern Gobi. Beginning at Lake Baikal, a valley, deep and broad, penetrates the north-western border-ridge of the plateau, and runs eastward up the river Uda, with an imperceptible gradient, like a gigantic railway cutting enclosed between two steep slopes, and it sends another branch south towards Kiakhta. After having served, through a succession of geological periods, as an outlet for the water and ice which accumulated on the plateau, it is now utilized for the two highways which lead from Lake Baikal across the plateau (3500–4000 ft.) to the Amur on the east and the Chinese depression on the south. Elsewhere the high and massive border-ridge on the north-western edge of the plateau can be crossed only by difficult footpaths. The border-ridge just mentioned, gapped by the wide opening of the Selenga, runs from south-west to north-east under different names, being known as Khamar-daban (6900 ft.) south of Lake Baikal, and as the Barguzin Mountains (7000 to 8000 ft.) along the east bank of the Barguzin river, while farther north-east it has been described under the names of the South Muya and the Chara Mountains (6000 to 7000 ft.). Resting its south-east base on the plateau, it descends steeply on the north-west to the lake and to the broad picturesque valleys of the Barguzin, Muya and Chara. Thick forests of larch, fir and cedar clothe the ridge, whose dome-shaped rounded summits (*goltsy*) rise above the limits of tree vegetation, but do not reach the snow-line (here above 10,000 ft.). The high plateau itself has the aspect of an undulating table-land, intersected by ranges, which rise some 1500 or 2000 ft. above its surface, and are separated by broad, flat, marshy valleys, traversed by sluggish meandering streams. The better drained valleys have fine meadow lands, while the hills are clothed with forests (almost exclusively of larch and birch). Numberless lakes and ponds occur along the river courses. Tunguses hunt in the forests and meadows, but permanent agricultural settlements are impossible, corn seldom ripening on account of the early frost. The lower parts of the broad, flat valley of the Jida have, however, a few Cossack settlements, and Mongolian shepherds inhabit the elevated grassy valleys about Lake Kosso-gol (5300 ft. above the sea). Quite different is the lower terrace of the plateau, occupied by the eastern Gobi and the Nerchinsk region, and separated from the upper terrace by the Yablonoi range. This last is the south-eastern border-ridge of the higher terrace. It rises to 8035 ft. in the Sokhondo peak, but elsewhere its dome-shaped summits do not exceed 5000 or 6000 ft. Numberless lakes, with flat undefined margins, feed streams which join the great north-going rivers or the Amur and the Pacific. Low hills rise above the edge of the plateau, but the slope is abrupt towards the south-east, where the foot-hills of the Yablonoi are nearly 1500 and 2000 ft. lower than on the north-west. Climate, flora and fauna change suddenly as soon as the Yablonoi has been crossed. The Siberian flora gives way to the Daurian flora, and this is in turn exchanged for the Pacific littoral flora on the Manchurian plains and lowlands.

The lower terrace has the character of a steppe, but is intersected by a number of ranges, plications of Silurian and Devonian rocks, all running south-west to north-east, and all containing silver, lead, copper and auriferous sands. Agriculture can be easily carried on in the broad prairies, the only drawbacks being droughts, and frosts in the higher closed valleys of the Nerchinsk or Gazimur Mountains. The lower terrace is in its turn fringed by a border-ridge—the Great Khingan—which occupies, with reference to the lower terrace, the same position that the Yablonoi does in relation to the upper, and separates Siberia from northern Manchuria. This important ridge does not run from south to north, as represented on the old maps, but from south-west to north-east; it is pierced by the Amur near Albazin, and joins the Okhotsk Mountains, which however do not join the Yoblonoi Mountains.

The rivers belong to three different systems—the affluents of Lake Baikal, of the Lena and of the Amur. Of the first the Selenga (800 m. long) rises in north-west Mongolia, one of its tributaries (the Egin-gol) being an emissary of Lake Kosso-gol. The Chikoi, Khilok and Uda are its chief tributaries in Transbaikalia. The Barguzin and the upper Angara enter Lake Baikal from the north-east. Of the tributaries of the Lena, the Vitim with its affluents (Karenga, Tsipa, and Muya) flows on the high plateau through uninhabited regions, as also does the Olekma. The tributaries of the Amur are much more important. The Arguñ, which at a quite recent epoch received the waters of the Dalai-nor, and thus had the Keruleñ for its source, is no longer in communication with the rapidly desiccating Mongolian lake, but has its sources in the Gan, which flows from the Great Khingan Mountains. It is not navigable, but receives the Gazimur and several other streams from the Nerchinsk mining district. The Shilka is formed by the union of the Onon and the Chita rivers, and is navigable from the town of Chita, thus being an important channel to the Amur.

Lake Baikal, with an area of 13,200 sq. m. (nearly equal to that of Switzerland), extends in a half crescent from south-west to north-east, with a length of nearly 400 m. and a width of 20 to 50 m. Its level is 1,500 ft. above the sea.[1] The wide delta of the Selenga narrows it in the middle, and renders it shallower in the east than in the west. The other lakes include the Gusinoye and Lake Ba-unt on the Vitim plateau. Many lakes yield common salt.

The high plateau is built up of granites, gneisses and syenites, overlain by Laurentian schists. Silurian and Devonian marine deposits occur only on the lower terrace. Since that epoch the region has not been under the sea, and only fresh-water Jurassic deposits and coal beds are met with in the depressions. During the Glacial period most of the high terrace and its border ridges were undoubtedly covered with vast glaciers. Volcanic rocks of more recent origin (Mesozoic?) are met with in the north-western border-ridge and on its slopes, as well as on the Vitim plateau. During the Glacial period the fauna of the lowest parts of Transbaikalia was decidedly arctic; while during the Lacustrine or post-Glacial periods this region was dotted over with numberless lakes, the shores of which were inhabited by Neolithic man. Only few traces of these survive, and they are rapidly drying up. Earthquakes are very frequent on the shores of Lake Baikal, especially at the mouth of the Selenga, and they extend as far as Irkutsk, Barguzin and Selenginsk; in 1862 an extensive area was submerged by the lake. Numerous mineral springs, some of them of high repute, exist all over Transbaikalia. The most important are the hot alkaline springs (130° F.) at Turka, at the mouth of the Barguzin, those of Pogromna on the Uda (very similar to the Seltzer springs), those of Molokova near Chita and those of Darasun in the Nerchinsk district.

The climate is, as a whole, exceedingly dry. The winter is cold and dry, the thermometer dropping as low as −58° F. But the snow is so trifling that the horses of the Buryats are able to procure food throughout the winter on the steppes, and in the very middle of the winter wheeled vehicles are used all over the west. To the east of the Yablonoi ridge the Nerchinsk district feels the influence of the North Pacific monsoons, and snow falls more thickly, especially in the valleys; but the summer is hot and dry. On the high plateau even the summer is cold, owing to the altitude and the humidity arising from the marshes, and the soil is frozen to a great depth. At Chita the daily range in summer and spring is sometimes as much as 33° to 46°. In the vicinity of Lake Baikal there is a cooler summer; in winter exceedingly deep snow covers the mountains around the lake.[2]

The estimated population in 1906 was 742,200. The Russian population is gathered around the mines of the Nerchinsk district, while the steppes are occupied by the Buryats. A string of villages has been planted along the Shilka between Chita and Stryetensk. The valleys of the Uda, the lower Selenga, and especially the Chikoi and the Khilok have been occupied since the beginning of the 19th century by Raskolniks, some of whom, living in a condition of prosperity such as is unknown in Russia proper, rank amongst the finest representatives of the Russian race. The remainder of the steppe of the Uda is occupied by Buryats, while the forests and marshes of the plateau are the hunting grounds of the nomad Tunguses. South of the Khamar-daban the only settled region is the lower valley of the Jida. On the Upper Arguñ the Cossacks are in features, character, language and manners largely Mongolian. The Russians along the Chinese frontier constitute a separate *voisko* or division of the Transbaikal Cossacks. The Buryats number about 180,000, the Tunguses over 30,000. The province is divided into five districts, the chief towns of which are Chita, the capital, Barguzin, Nerchinsk, Selenginsk and Verkhneudinsk.

Although a good deal of land has been cleared by the settlers, nearly one-half of the entire area is still covered with forests. The principal varieties are fir, larch, aspen, poplar and birch, with *Abies pectinata* in the north and the cedar in the south. Only about one-third of the surface is adaptable for cultivation, and of that only about one-tenth is actually under tillage.

Agriculture is carried on to a limited extent by the Buryats and in all the Russian settlements; but it prospers only in the valleys of West Transbaikalia, and partly in the Nerchinsk region, while in the steppes of the Arguñ and Onon even the Russians resort to pastoral pursuits and trade, or to hunting. Livestock rearing is extensively carried on, especially by the Buryats, but their herds and flocks are often destroyed in great numbers by the snowstorms of spring. Hunting is an important occupation, even with the Russians, many of whom leave their homes in October to spend six weeks in the *taiga* (forest region). The fisheries of Lake Baikal and the lower parts of its affluents are important. Enormous quantities of *Salmo omul* are taken every year; and *S. thymalus*, *S. oxyrhynchus* and *S. fluviatilis* are also taken. Mining, and especially gold mining, is important, but the production of gold has fallen off. Silver mines have only a very small output. Iron mining is gradually developing, and good coal mines are now being worked. Salt is raised from several lakes, and the extraction of Epsom salts has considerably developed. Manufactures, though insignificant, have increased. The trade is chiefly concentrated at Kiakhta. The Cossacks on the frontier traffic in brick-tea, cattle and hides with Mongolia. The export of furs is of considerable value.

Transbaikalia is crossed by the Trans-siberian railway from Mysovaya on Lake Baikal, via Chita, to Stryetensk, and from Kaidalovo, near Chita, to the Mongolian frontier; the latter section is continued across Manchuria to Vladivostok and Port Arthur. Regular steamer communication has been established along Lake Baikal, not only for the transport of passengers and goods between the two railway stations of Listvinichnoye and Mysovaya, but also with the object of developing the fishing industry, which is of great importance. Steamers ply up the Selenga river as far as Selenginsk, considerable cargoes of tea being transported along this line.

(P. A. K.; J. T. BE.)

[1] There is uncertainty as to the absolute altitude (see BAIKAL).

[2] See "Das Klima von Ost-Siberien," by A. Woyeikow, in *Meteorol. Zeitschrift* (1884).

TRANSCASPIAN REGION, a Russian territory on the E. of the Caspian, bounded S. by Khorasan and Afghanistan, N. by the Russian province of Uralsk, N.E. by Khiva and Bokhara and S.E. by Afghan Turkestan. Area, 212,545 sq. m. Some of the most interesting problems of geography, such as those relating to the changes in the course of the Jaxartes (Syr-darya) and the Oxus (Amu-darya), and the supposed periodical disappearance of Lake Aral, are connected with the Transcaspian deserts; and it is here that we must look for a clue to the physical changes which transformed the Euro-Asiatic Mediterranean—the Aral-Caspian and Pontic basin—into a series of separate seas, and desiccated them, powerfully influencing the distribution of floras and faunas, and centuries ago compelling the inhabitants of Western and Central Asia to enter upon their great migrations. But down to a comparatively recent date the arid, barren deserts, peopled only by wandering Turkomans, were almost a *terra incognita*.

A mountain chain, comparable in length to the Alps, separates the deserts of the Transcaspian from the highlands of Khorasan. It begins in the Krasnovodsk peninsula of the Caspian, under the names of Kuryanyn-kary and Great Balkans, whose masses of granite and other crystalline rock reach an altitude of some 5350 ft. Farther south-east they are continued in the Little Balkans (2000 ft.) and the Kopepet-dagh or Kopet-dagh. The latter rises steep and rugged above the flat deserts over a stretch of 600 m. In structure it is homologous with the Caucasus chain; it appears as an outer wall of the Khorasan plateau, and is separated from it by a broad valley, which, like the Rion and Kura valley of Transcaucasia, is drained by two rivers flowing in opposite directions—the Atrek, which flows north-west into the Caspian, and the Keshef-rud, which flows to the south-east and is a tributary of the Murghab. On the other side of this valley the Alla-dagh (Aladagh) and the Binalund border-ranges (9000 to 11,000 ft.) fringe the edge of the Khorasan plateau. Descending towards the steppe with steep stony slopes, the mountain barrier of the Kopet-dagh rises to heights of 6000–9000 ft. to the east of Kyzyl-arvat, while the passes which lead from the Turkoman deserts to the valleys of Khorasan are seldom as low as 3500, and usually rise to 5000, 6000 and even 8500 ft., and in most cases are very difficult. It is pierced by only one wide opening, that between the Great and Little Balkans, through which the sea, which once covered the steppe, maintained connexion with the Caspian.

While the Alla-dagh and Binalund border-ranges are chiefly composed of crystalline rocks and metamorphic slates, overlain by Devonian deposits, a series of more recent formations—Upper and Lower Cretaceous and Miocene—crops out in the outer wall of the Kopet-dagh. Here again we find that the mountains of Asia which stretch towards the north-west continued to be uplifted at a geologically recent epoch. Quarternary deposits have an extensive development on its slopes, and its foothills are bordered by a girdle of loess.

The loess terrace, called Atok (" mountain base "), 10 to 20 m. in width, is very fertile; but it will produce nothing without irrigation, and the streams flowing from the Kopet-dagh are few and scanty. The winds which impinge upon the northern slope of the mountains have been deprived of all their moisture in crossing the Kara-kum—the Black Sands of the Turkoman desert; and even such rain as falls on the Kopet-dagh (10½ in. at Kyzyl-arvat) too often reaches the soil in the shape of light showers which do not penetrate it, so that the average relative humidity is only 56 as compared with 62 at even so dry a place as Krasnovodsk. Still, at those places where the mountain streams run closer to one another, as at Geok-tepe, Askhabad, Lutfabad and Kaaka, the villages are more populous, and the houses are surrounded by gardens, every square yard and every tree of which is nourished by irrigation.

North of this narrow strip of irrigated land begins the desert—the Kara-kum—which extends from the mountains of Khorasan to Lake Aral and the plateau of Ust-Urt, and from the Caspian to the Amu-darya, interrupted only by the oases of Merv and Tejeñ. But the terrible shifting sands, blown into *barkhans*, or elongated hills, sometimes 50 and 60 ft. in height, are accumulated chiefly in the west, where the country has more recently emerged from the sea. Farther east the barkhans are more stable. Large areas amidst the sands are occupied by *takyrs*, or flat surfaces paved with clay, which, as a rule, is hard but becomes almost impassable after heavy rains. In these takyrs the Turkomans dig ditches, draining into a kind of cistern, where the water of the spring rains can be preserved for a few months. Wells also are sunk, and the water is found in them at depths of 10 to 50, or occasionally 100 ft. and more. All is not desert in the strict sense; in spring there is for the most part a carpet of grass.

The vegetation of the Kara-kum cannot be described as poor. The typical representative of the sandy deserts of Asia, the saksaul (*Anabasis ammodendron*), has been almost destroyed within the last hundred years, and occurs only sporadically, but the borders of the spaces covered with saline clay are brightened by forests of tamarisk, which are inhabited by great numbers of the desert warbler (*Atraphornis aralensis*)—a typical inhabitant of the sands—sparrows and ground-choughs (*Podoces*); the *Houbara macqueeni*, though not abundant, is characteristic of the region. Hares and foxes, jackals and wolves, marmots, moles, hedgehogs and one species of marten live in the steppe, especially in spring. As a whole, the fauna is richer than might be supposed, while in the Atok it contains representatives of all the species known in Turkestan, intermingled with Persian and Himalayan species.

The Uzboi.—A feature distinctive of the Turkoman desert is the very numerous *shors*, or elongated depressions, the lower portion of which are mostly occupied with moist sand. They are obviously the relics of brackish lakes, and, like the lakes of the Kirghiz steppes, they often follow one another in quick succession, thus closely resembling river-beds. As the direction of the *shors* is generally from the higher terraces drained by the Amu-darya towards the lowlands of the Caspian, they were usually regarded as old beds of the Amu-darya, and were held to support the idea of its once having flowed across the Turkoman desert towards what is now the Caspian Sea. It was formerly considered almost settled, not only that that river (see OXUS) flowed into the Caspian during historical times, but that after having ceased to do so in the 7th century, its waters were again diverted to the Caspian about 1221. A chain of elongated depressions, bearing a faint resemblance to old river-beds, was traced from Urgenj to the gap between the Great and the Little Balkans; this was marked on the maps as the Uzboi, or old bed of the Oxus.[1] The idea of again diverting the Amu into the Caspian was thus set afloat, but the investigations of Russian engineers, especially A. E. Hedroitz, A. M. Konshin, I. V. Mushketov, P. M. Lessar and Svintsov,[2] went to show that the Uzboi is no river-bed at all, and that no river has ever discharged its waters in that direction. The existence of an extensive lacustrine depression, now represented by the small Sary-kamysh lakes, was proved, and it was evident that this depression, having a length of more than 130 m., a width of 70 m., and a depth of 280 ft. below the present level of Lake Aral, would have to be filled by the Amu before its waters could advance farther to the south-west. The sill of this basin being only 28 ft. below the present level of Lake Aral, this latter could not be made to disappear, nor even be notably reduced in size, by the Amu flowing south-west from Urgenj. A more careful exploration of the Uzboi has shown that, while the deposits in the Sary-kamysh depression, and the Aral shells they contain, bear unmistakable testimony to the fact of the basin having once been fed by the Amu-darya, no such traces are found along the Uzboi below the Sary-kamysh depression;[3] on the contrary, shells of molluscs still inhabiting the Caspian are found in numbers all along it, and the supposed old bed has all the characteristics of a series of lakes which continued to subsist along the foothills of the Ust-Urt plateau, while the Caspian was slowly receding westwards during the post-Pliocene period. On rare occasions only did the waters of the Sary-kamysh, when raised by inundations above the sill just mentioned, send their surplus into the Uzboi. It appears most probable that in the 16th century the Sary-kamysh was confounded with a gulf of the Caspian;[4] and this gives much plausibility to Konshin's supposition that the changes in the lower course of the Amu (which no geologist would venture to ascribe to man, if they were to mean the alternative discharge of the Amu into the Caspian and Lake Aral) merely meant that by means of appropriate dams the Amu was made to flow in the 13th–16th centuries alternately into Lake Aral and into the Sary-kamysh.

The ancient texts (of Pliny, Strabo, Ptolemy) about the Jaxartes and Oxus only become intelligible when it is admitted that, since the epoch to which they relate, the outlines of the Caspian Sea and Lake Aral have undergone notable changes, commensurate with those which are supposed to have occurred in the courses of the Central Asian rivers. The desiccation of the Aral-Caspian basin proceeded with such rapidity that the shores of the Caspian cannot possibly have maintained for some twenty centuries the outlines which they exhibit at present. When studied in detail, the general configuration of the Transcaspian region leaves no doubt that both the Jaxartes and the Oxus, with its former tributaries, the Murghab and the Tejeñ, once flowed towards the west; but the Caspian of that time was not the sea of our days; its gulfs penetrated the Turkoman steppe, and washed the base of the Ust-Urt plateau. (See CASPIAN and ARAL.)

Kelif-Uzboi.—There is also no doubt that, instead of flowing north-westward of Kelif (on the present Bokhara-Afghan frontier), the Amu once bent south to join the Murghab and Tejeñ; the chain of depressions described by the Russian engineers as the Kelif-Uzboi[5] supports this hypothesis, which a geographer cannot avoid making when studying a map of the Transcaspian region; but the date at which the Oxus followed such a course, and the extension which the Caspian basin then had towards the east, are uncertain.

In 1897 the population numbered 377,416, of whom only 42,431 lived in towns; but, besides those of whom the census took account, there were about 25,000 strangers and troops.

[1] On the original Russian map of the Transcaspian, drawn immediately after the survey of the Uzboi had been completed, the Uzboi has not the continuity which is given to it on subsequent maps.

[2] Their original papers are printed in the *Izvestia* of the Russian Geographical Society, 1883 to 1887, also in the *Journal* of the Russian ministry of roads and communications.

[3] According to A. E. Hedroitz and A. M. Konshin the old Tonu-darya bed of the Amu contains shells of molluscs now living in the Amu (*Cyrena fluminalis*, *Dreissensia polymorpha* and *Anodonta*). The Sary-kamysh basin is characterized by deposits containing *Neritina liturata*, *Dreissensia polymorpha* and *Limnaeus*, characteristic of this basin. Below the Sary-kamysh there are no deposits containing shells characteristic of the Amu; *Anodontae* are found quite occasionally on the surface, not in beds, in company with the Caspian *Cardium* (*Didacna*) *trigonoides*, var. *crassum*, *Cardium piramidatum*. *Dreissensia polymorpha*, *D. rostriformis*, *Hydrobia caspia*, *Neritina liturata* and *Dreissensia beardii*; the red clays containing these fossils extend for 130 m. east of the Caspian (*Izvestia* of Russ. Geog. Soc., 1883 and 1886).

[4] As by Jenkinson, who mentions a freshwater gulf of the Caspian within six days' march from Khwarezm (or Khiva), by which gulf he could only mean the Sary-kamysh depression.

[5] The Turkomans call this southern " old bed " Unghyuz or Onguz (" dry old bed "), and there can be no doubt that when the *Bolshoi-Chertezh* of the 16th century (speaking from anterior information) mentions a river, Ughyuz or Ugus, flowing west from the Amu towards the Caspian, it is merely describing as a river what the very name shows to have been a dry bed, supposed to have been once occupied by a river. The similarity of the names Ongus and Ugus with Ogus and Ochus possibly helped to accentuate, if not to give rise to, the confusion. Cf. N. G. Petrusevich, " The South-east Shores of the Caspian," in *Zapiski* of the Caucasian Geographical Society (1880), vol. xi.

Included in the total were some 280,000 Turkomans, 60,000 Kirghiz, 12,000 Russians, 8000 Persians, 4250 Armenians, and some Tatars. The estimated population in 1906 was 397,100. The province is divided into five districts, the chief towns of which are Askhabad, the capital; Krasnovodsk; Fort Alexandrovskiy, in the district of Manghishlak, on the Caspian Sea; Merv and Tejeñ. Until a recent date the chief occupations of the Turkomans were cattle-rearing and robbery. Even those who had settled abodes on the oases of the Atok, Tejeñ and Merv were in the habit of encamping during the spring in the steppes, the khanates of Afghan Turkestan from Balkh to Meshhed being periodically devastated by them. The aspect of the steppe has, however, greatly changed since the Russian advance and the fall (1881) of the Turkoman stronghold of Geok-tepe. Their principal oases are situated along the Atok or loess terrace, the chief settlements being Askhabad, Kyzyl-arvat and Geok-tepe. The oasis of Merv is inhabited by Akhal-tekkes (about 240,000), mostly poor. In January 1887 they submitted to Russia. The oasis of Tejeñ has sprung up where the river Tejeñ (Heri-rud) terminates in the desert.

South-west Turcomania.—The region between the Heri-rud and the Murghab has the characteristics of a plateau, reaching about 2000 ft. above the sea, with hills 500 and 600 ft. high covered with sand, the spaces between being filled with loess. The Borkhut Mountains which connect the Kopet-dagh with the Sefid-kuh in Afghanistan reach 3000 to 4000 ft., and are cleft by the Heri-rud. Thickets of poplar and willow accompany both the Murghab and the Heri-rud. Pistachio and mulberry trees grow in isolated clumps on the hills; but there are few places available for cultivation, and the Saryk Turkomans (some 60,000 in number) congregate in only two oases—Yol-otan or Yelatan, and Penjdeh. The Sarakhs oasis is occupied by the Salor Turkomans, hereditary enemies of the Tekke Turkomans; they number about 3000 tents at Old Sarakhs, and 1700 more on the Murghab, at Chardjui, at Maimene (or Meimane), and close to Herat.

The Transcaspian Region is very rich in minerals. Rock-salt, petroleum, gypsum and sulphur are extracted. Nearly 300,000 acres are irrigated by the natives, and attempts are being made by the government to increase the irrigated area; it is considered that over 5,000,000 acres of land could be rendered suitable for agriculture. Several hundred thousand trees are planted every year, and a forest guard has been established to prevent useless destruction of the saksaul trees, which grow freely in the steppes. A model garden and a mulberry plantation have been established at Askhabad in connexion with the gardening school. The land in the oases, especially those of the Atrek River, is highly cultivated. Wheat and barley are grown, in addition to sorghum (a species of millet), maize, rice, millet and sesame for oil. Raw cotton is extensively grown in the Merv district. Gardening and fruit-growing are well developed, and attempts are being made to encourage the spread of viticulture. Livestock breeding is the chief occupation of the nomad Turkomans and Kirghiz. Considerable fishing is carried on in the Caspian Sea, and seals are killed off the Manghishlak peninsula. The natives excel in domestic industries, as the making of carpets, travelling bags, felt goods and embroidered leather. The Russian population is mostly limited to the military and the towns. Wheat, flour, wool, raw cotton and dried fruit are exported; while tea, manufactured goods, timber, sugar, iron and paraffin oil are imported, as also rice and fruit from Bokhara, Turkestan and Persia. The Transcaspian railway, constructed across the province from Krasnovodsk to Merv, with a branch to Kushk, and from Merv to Bokhara and Russian Turkestan, has effected quite a revolution in the trade of Central Asia. The old caravan routes via Orenburg have lost their importance, and goods coming from India, Persia, Bokhara and even China are now carried by rail. (For the history of the region see MERV.)

See the researches of Andrusov, Bogdanovich, Konshin, Mushketov and Obruchev in the *Memoirs*, the *Bulletin* (*Izvestia*) and the *Annuals* of the Russian Geographical Society (1890–1900); P. M. Lessar, *L'Ancienne jonction de l'Oxus avec la mer Caspienne* (1889); Zarudnoi (zoology) in *Bulletin de la société des naturalistes de Moscou* (1889 seq.). (P. A. K.; J. T. BE.)

TRANSCAUCASIA, a general name given to the governments and provinces of Russian Caucasia, excluding the steppe provinces of Kuban and Terek and the steppe government of Stavropol. It thus includes the governments of Baku, Elisavetpol, Erivan, Kutais and Tiflis; the provinces of Batum, Daghestan and Kars; and the military districts of the Black Sea (Chernomorsk) and Zakataly. Its area is 95,402 sq. m., and the estimated population in 1906 was 6,114,600. (See CAUCASIA and CAUCASUS.)

TRANSCENDENTALISM (Lat. *trans*, across, *scandere*, climb, whence *transcendere*, to pass a limit), in philosophy, any system which emphasizes the limited character of that which can be perceived by the senses and is based on the view that true knowledge is intuitive, or supernatural. The term is specially applied to Kant's philosophy and its successors which hold that knowledge of the a priori is possible. It is traceable as far back as the schoolmen of whom Duns Scotus describes as "transcendental" those conceptions which have a higher degree of universality than the Aristotelian categories. Thus *ens* (being) is more universal than God or the physical universe because it can be predicated of both. Kant distinguishes as "transcendent" the world of things-in-themselves as being without the limits of experience; while "transcendental" is his term for those elements which regulate human experience, though they are themselves beyond experience; such are the categories of space, time, causality.

In general use the term is applied rather promiscuously and frequently by way of criticism to an attitude of mind which is imaginative, aloof from mundane affairs and unmoved by practical considerations. The most famous example of the pseudo-philosophic use of the term is for a movement of thought which was prominent in the New England states from about 1830 to 1850. Its use originated in the Transcendental Club (1836) founded by Emerson, Frederic Henry Hedge (1805–1890), and others. This movement had several aspects: philosophical, theological, social, economic. Its main theme was regeneration, a revolt from the formalism of both Unitarian and Calvinist theology and a widening literary outlook. It took its rise to a large extent in the study of German (and to a less extent French) philosophy and spread widely among the cultured classes. In 1840 the club began to issue an official organ, *The Dial*, and the settlement of Brook Farm (*q.v.*) followed in 1841. These enterprises themselves did not receive general support even among the Transcendentalist leaders, and the real significance of the movement was the stimulus which it gave to philanthropy, to the Abolition movement, and to a new ideal of individual character. The chief names associated with it, besides those of Emerson and Hedge, are those of A. B. Alcott (*q.v.*), Margaret Fuller (*q.v.*), George Ripley (*q.v.*), W. E. Channing (*q.v.*), and H. D. Thoreau (*q.v.*).

TRANSEPT (from Lat. *trans*, across, and *septum*, enclosure; synonymous terms in other languages are Fr. *croisée*, *nef transversée*; Ital. *crociata*; Ger. *Querbau*, *Querschiff*), in architecture, the term given to the large and lofty structure which lies at right angles to the nave and aisles of a church. The first example is that which existed in the old St Peter's at Rome, but as a rule it is not found in the early basilicas. At the present day the transept might be better defined as that portion of a cruciform church which extends from north to south across the main body of the building and usually separates the choir from the nave; but to this there are some exceptions, as in Westminster Abbey, where the choir, with its rood screen, occupies the first four bays of the nave; in Norwich two bays; in Gloucester one bay; and Winchester one bay. In some of the English cathedrals there is an eastern transept, as in Canterbury, Lincoln, Salisbury and Worcester; at Durham that which might be regarded as an eastern transept is the chapel of the Nine Altars, and the same is found in Fountains Abbey. Four of the English cathedrals have aisles on east and west sides, viz. Ely, Wells, Winchester and York, while at Chester there are aisles to the south transept only, and at Lincoln, Peterborough and Salisbury on the east side only. In some cases the transept extends to the outer walls of the aisles only, but there are many instances in which it is carried beyond, as at Lincoln (225 ft. long), Ely (180 ft.), Peterborough (180 ft.), Durham (175 ft.) and Norwich (172 ft.); in all these cases the transept is carried three bays beyond; in York (220 ft.), St Albans (170 ft.), Lichfield (145 ft.) and Canterbury, east transept (165 ft.), two bays beyond; and in Canterbury, western transept (130 ft.), Chichester (160 ft.) and Worcester (130 ft.), only one bay on each side, the dimension in all cases being taken within the north and south walls of the transept.

TRANSFER (from Lat. *transferre*, to bear across, carry over), the handing over, removal or conveyance of anything from one person or place to another; also the subject of this transference or the form or method by which it is effected. The term is particularly used in law of the conveyance of property from one person to another, especially of the conveyance of real property (see CONVEYANCING). For the simplification of this process by means of registration of title, see LAND REGISTRATION. For the transference of designs, drawings, &c., by means of transfer-paper to the surface of pottery and porcelain, see CERAMICS; for their transfer to stones for printing, see LITHOGRAPHY.

TRANSFORMERS. An electrical transformer is the name given to any device for producing by means of one electric current another of a different character. The working of such an appliance is, of course, subject to the law of conservation of energy. The resulting current represents less power than the applied current, the difference being represented by the power dissipated in the translating process. Hence an electrical transformer corresponds to a simple machine in mechanics, both transforming power from one form into another with a certain energy-dissipation depending upon frictional losses, or something equivalent to them. Electrical transformers may be divided into several classes, according to the nature of the transformation effected. The first division comprises those which change the form of the power, but keep the type of the current the same; the second those that change the type of the current as well as the form of power. The power given up electrically to any circuit is measured by the product of the *effective value* of the current, the *effective value* of the difference of potential between the ends of the circuit and a factor called the *power factor*. In dealing with periodic currents, the effective value is that called the root-mean-square value (R.M.S.), that is to say, the square root of the mean of the squares of the time equidistant instantaneous values during one complete period (see ELECTROKINETICS). In the case of continuous current, the power factor is unity, and the effective value of the current or voltage is the true mean value. As the electrical measure of a power is always a product involving current and voltage, we may transform the character of the power by increasing or diminishing the current with a corresponding decrease or increase of the voltage. A transformer which raises voltage is generally called a *step-up* transformer, and one which lowers voltage a *step-down* transformer.

Again, electric currents may be of various types, such as continuous, single-phase alternating, polyphase alternating, undirectional but pulsating, &c. Accordingly, transformers may be distinguished in another way, in accordance with the type of transformation they effect. (1) *An alternating current transformer* is an appliance for creating an alternating current of any required magnitude and electromotive force from another of different value and electromotive force, but of the same frequency. An alternating current transformer may be constructed to transform either single-phase or polyphase currents. (2) *A continuous current transformer* is an appliance which effects a similar transformation for continuous currents, with the difference that some part of the machine must revolve, whereas in the alternating current transformer all parts of the machine are stationary; hence the former is generally called a rotatory transformer, and the latter a static transformer. (3) *A rotatory or rotary transformer* may consist of one machine, or of two separate machines, adapted for converting a single-phase alternating current into a polyphase current, or a polyphase current into a continuous current, or a continuous current into an alternating current. If the portions receiving and putting out power are separate machines, the combination is called a *motor-generator*. (4) A transformer adapted for converting a single-phase alternating current into a unidirectional but pulsatory current is called a *rectifier*, and is much used in connexion with arc lighting in alternating current supply stations. (5) *A phase transformer* is an arrangement of static transformers for producing a polyphase alternating current from a single-phase alternating current. Alternating current transformers may be furthermore divided into (*a*) single-phase, (*b*) polyphase. Transformers of the first class change an alternating current of single-phase to one of single-phase identical frequency, but different power; and transformers of the second class operate in a similar manner on polyphase currents. (6) The ordinary induction or spark coil may be called an intermittent current transformer, since it transforms an intermittent low-tension primary current into an intermittent or alternating high-tension current.

Alternating Current Transformer.—The typical alternating current transformer consists essentially of two insulated electric circuits wound on an iron core constituting the magnetic circuit. They may be divided into (1) open magnetic circuit static transformers, and (2) closed magnetic circuit static transformers, according as the iron core takes the form of a terminated bar or a closed ring. A closed circuit alternating current transformer consists of an iron core built up of thin sheets of iron or steel, insulated from one another, and wound over with two insulated conducting circuits, called the primary and secondary circuits. The core must be laminated or built up of thin sheets of iron to prevent local electric currents, called eddy currents, from being established in it, which would waste energy. In practical construction, the core is either a simple ring, round or rectangular, or a double rectangular ring, that is, a core whose section is like the figure 8. To prepare the core, thin sheets of iron or very mild steel, not thicker than ·014 of an inch, are stamped out of special iron (see ELECTROMAGNETISM) and carefully annealed.

The preparation of the particular sheet steel or iron used for this purpose is now a speciality. It must possess extremely small hysteresis loss (see MAGNETISM), and various trade names, such as "stalloy," "lohys," are in use to describe certain brands. Barrett, Brown and Hadfield have shown (*Journ. Inst. Elec. Eng. Lond.*, 1902, 31, p. 713) that a silicon iron containing 2·87% of silicon has a hysteresis loss far less than that of the best Swedish soft iron. In any case the hysteresis loss should not exceed 3·0 watts per kilogram of iron measured at a frequency of 50 ∼ and a flux-density of 10,000 lines per square centimetre. This is now called the "figure of merit" of the iron.

Examples of the shapes in which these stampings are supplied are shown in fig. 1. The plates when annealed are varnished or covered with thin paper on one side, and then piled up so as to make an iron core, being kept together by bolts and nuts or by pressure plates. The designer of a transformer core has in view, first, economy in metal, so that there may be no waste fragments, and second, a mode of construction that facilitates the winding of the wire circuits. These consist of coils of cotton-covered copper wire which are wound on formers and baked after being well saturated with shellac varnish. The primary and secondary circuits are sometimes formed of separate bobbins which are sandwiched in between each other; in other cases they are wound one over the other (fig. 2).

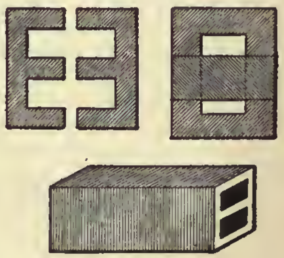

FIG. 1.

In any case the primary and secondary coils must be symmetrically distributed. If they were placed on opposite sides of the iron circuit the result would be considerable magnetic leakage. It is usual to insert sheets or cylinders of micanite between the primary and secondary windings. The transformer is then well baked and placed in a cast-iron case sometimes filled in with heavy insulating oil, the ends of the primary and secondary circuits being brought out through water-tight glands. The most ordinary type of alternating current transformer is one intended to transform a small electric current produced by a large electromotive force (2000 to 10,000 volts) into a larger current of low electromotive force (100 to 200 volts). Such a step-down transformer may be obviously employed in the reverse direction for raising pressure and reducing current, in which case it is a step-up transformer. A transformer when manufactured has to be carefully tested to ascertain, first, its power of resisting breakdown, and, second, its energy-dissipating qualities. With the first object, the transformer is subjected to a series of pressure tests. If it is intended that the primary shall carry a current

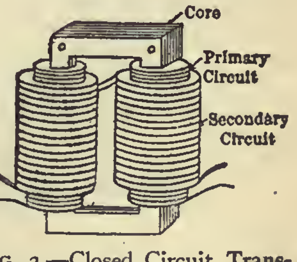

FIG. 2.—Closed Circuit Transformer.

produced by an electromotive force of 2000 volts, an insulation test must be applied with double this voltage between the primary and the secondary, the primary and the case, and the primary and the core, to ascertain whether the insulation is sufficient. To prevent electric discharges from breaking down the machine in ordinary work, this extra pressure ought to be applied for at least a quarter of an hour. In some cases three or four times the working pressure is applied for one minute between the primary and secondary circuits. When such an alternating current transformer has an alternating current passed through its primary circuit, an alternating magnetization is produced in the core, and this again induces an alternating secondary current. The secondary current has a greater or less electromotive force than the primary current according as the number of windings or turns on the secondary circuit is greater or less than those on the primary. Of the power thus imparted to the primary circuit one portion is dissipated by the heat generated in the primary and secondary circuits by the currents, and another portion by *the iron core losses* due to the energy wasted in the cyclical magnetization of the core; the latter are partly eddy current losses and partly hysteresis losses.

In open magnetic circuit transformers the core takes the form of a laminated iron bar or a bundle of iron wire. An ordinary induction coil is an instrument of this description. It has been shown, however, by careful experiments, that for alternating current transformation there are very few cases in which the closed magnetic circuit transformer has not an advantage. An immense number of designs of closed circuit transformers have been elaborated since the year 1885. The principal modern types are the Ferranti, Kapp, Mordey, Brush, Westinghouse, Berry, Thomson-Houston and Ganz. Diagrammatic representations of the arrangements of the core and circuits in some of these transformers are given in fig. 3.

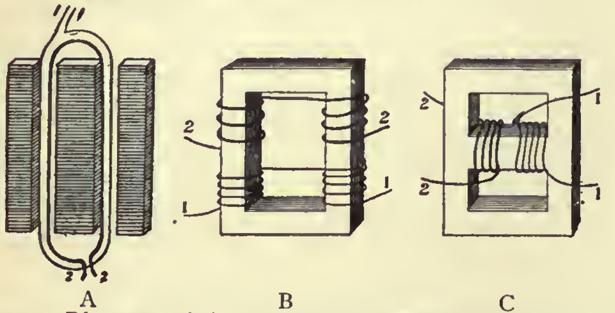

FIG. 3.—Diagrams of (A) Mordey (in section), (B) Kapp and (C) Ganz Transformers.

1, 1 Primary circuit; 2, 2 Secondary circuit.

Alternating current transformers are classified into (i.) *Core* and (ii.) *Shell* transformers, depending upon the arrangements of the iron and copper circuits. If the copper circuits are wound on the outside of what is virtually an iron ring, the transformer is a core transformer; if the iron encloses the copper circuits, it is a shell transformer. Shell transformers have the disadvantage generally of poor ventilaton for the copper circuits. Berry, however, has overcome this difficulty by making the iron circuit in the form of a number of bunches of rectangular frames which are set in radial fashion and the adjacent legs all embraced by the two copper circuits in the form of a pair of concentric cylinders. In this manner he secures good ventilation and a minimum expenditure in copper and iron, as well as the possibility of insulating the two copper circuits well from each other and from the core. An important matter is the cooling of the core. This may be effected either by ordinary radiation, or by a forced draught of air made by a fan or else by immersing the transformer in oil, the oil being kept cool by pipes through which cold water circulates immersed in it. This last method is adopted for large high-tension transformers.

Efficiency.

The ratio between the power given out by a transformer and the power taken up by it is called its *efficiency*, and is best represented by a curve, of which the ordinate is the efficiency expressed as a percentage, and the corresponding abscissae represent the fractions of the full load as decimal fractions. The output of the transformer is generally reckoned in kilowatts, and the load is conveniently expressed in decimal fractions of the full load taken as unity. The efficiency on one-tenth of full load is generally a fairly good criterion of the economy of the transformer as a transforming agency. In large transformers the one-tenth load efficiency will reach 90% or more, and in small transformers 75 to 80%. The general form of the efficiency curve for a closed circuit transformer is shown in fig. 4. The horizontal distances represent fractions of full secondary load (represented by unity), and the vertical distances efficiency in percentages. The efficiency curve has a maximum value corresponding to that degree of load at which the copper losses in the transformer are equal to the iron losses.

In the case of modern closed magnetic circuit transformers the copper losses are proportional to the square of the secondary current (I_2) or to qI_2^2, where $q = R_1a^2 + R_2$; R_1 being the resistance of the primary and R_2 that of the secondary circuit, while a is the ratio of the number of secondary and primary windings of the transformer. Let C stand for the core loss, and V_2 for the secondary terminal potential difference (R.M.S. value). We can then write as an expression for the efficiency (η) of the transformer ($\eta = I_2V_2/(C + qI_2^2 + I_2V_2)$. It is easy to show that if C_1, V_2 and q are constants, but I_2 is variable, the above expression for η has a maximum value when $C - qI_2^2 = O$, that is, when the iron core loss C = the total copper losses qI_2^2.

Iron and Copper Losses.

The iron core energy-waste, due to the hysteresis and eddy currents, may be stated in watts, or expressed as a fraction of the full load secondary output. In small transformers of 1 to 3 kilowatts output it may amount to 2 or 3%, and in large transformers of 10 to 50 kilowatts and upwards it should be 1 or less than 1%. Thus the core loss of a 30-kilowatt transformer (one having a secondary output of 30,000 watts) should not exceed 250 watts.

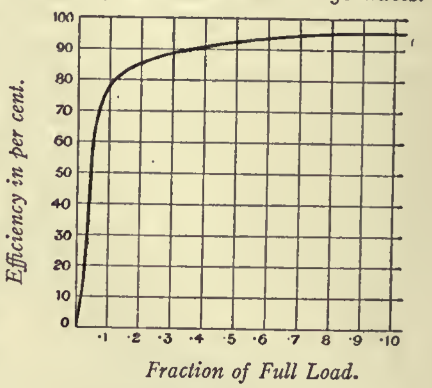

FIG. 4.—Typical Efficiency Curve of Closed Circuit Transformer.

It has been shown that for the constant potential transformer the iron core loss is constant at all loads, but diminishes slightly as the core temperature rises. On the other hand, the copper losses due to the resistance of the copper circuits increase about 0·4% per degree C. with rise of temperature. The current taken in at the primary side of the transformer, when the secondary circuit is unclosed, is called the *magnetizing current*, and the power then absorbed by the transformer is called the *open circuit loss* or magnetizing watts. The ratio of the terminal potential difference at the primary and secondary terminals is called the *transformation ratio* of the transformer. Every transformer is designed to give a certain transformation ratio, corresponding to some particular primary voltage. In some cases transformers are designed to transform, not potential difference, but current in a constant ratio. The product of the root-mean-square (R.M.S.), effective or virtual, values of the primary current, and the primary terminal potential difference, is called the *apparent power* or apparent watts given to the transformer. The true electrical power may be numerically equal to this product, but it is never greater, and is sometimes less. The ratio of the true power to the apparent power is called the *power factor* of the transformer. The power factor approaches unity in the case of a closed circuit transformer, which is loaded non-inductively on the secondary circuit to any considerable fraction of its full load, but in the case of an open circuit transformer the power factor is always much less than unity at all loads. Power factor curves show the variation of power factor with load. Examples of these curves were first given by J. A. Fleming, who suggested the term itself (see *Jour. Inst. Elec. Eng. Lond.*, 1892, 21, p. 606). A low power factor always implies a magnetic circuit of large reluctance.

The operation of the alternating current is then as follows: the periodic magnetizing force of the primary circuit creates a periodic magnetic flux in the core, and this being linked with the primary circuit creates by its variation what is called the back electromotive force in the primary circuit. The variation of the particular portion of this periodic flux, linked with the secondary circuit, originates in this last a periodic electromotive force. The whole of the flux linked with the primary circuit is not interlinked with the secondary circuit. The difference is called the *magnetic leakage* of the transformer. This leakage is increased with the secondary output of the transformer and with any disposition of the primary and secondary coils which tends to separate them. The leakage exhibits itself by increasing the *secondary drop*. If a transformer is worked at a constant primary potential difference, the secondary terminal potential difference at no load or on open secondary circuit is greater than it is when the secondary is closed and the transformer giving its full output. The difference between these last two differences of potential is called the secondary drop. This secondary drop should not exceed 2 % of the open secondary circuit potential difference.

Appraisement.

The facts required to be known about an alternating current transformer to appraise its value are (1) its full load secondary output or the numerical value of the power it is designed to transform, on the assumption that it will not rise in temperature more than about 60° C. above the atmosphere when in normal use; (2) the primary and secondary terminal voltages and currents, accompanied by a statement whether the transformer is intended for producing a constant secondary voltage or a constant secondary current; (3) the efficiency at various fractions on secondary load from one-tenth to full load taken at a stated frequency; (4) the power factor at one-tenth of full load and at full load; (5) the secondary drop between full load and no load; (6) the iron core loss, also the magnetizing current, at the normal frequency; (7) the total copper losses at full load and at one-tenth of full load; (8) the final temperature of the transformer after being left on open secondary circuit but normal primary potential for twenty-four hours, and at full load for three hours.

The matters of most practical importance in connexion with an alternating current transformer are (1) the iron core loss, which affects the efficiency chiefly, and must be considered (*a*) as to its initial value, and (*b*) as affected by "ageing" or use; (2) the secondary drop or difference of secondary voltage between full and no load, primary voltage being constant, since this affects the service and power of the transformer to work in parallel with others; and (3) the temperature rise when in normal use, which affects the insulation and life of the transformer. The shellacked cotton, oil and other materials with which the transformer circuits are insulated suffer a deterioration in insulating power if continuously maintained at any temperature much above 80° C. to 100° C. In taking the tests for core loss and drop, the temperature of the transformer should therefore be stated. The iron losses are reduced in value as temperature rises and the copper losses are increased. The former may be 10 to 15 % less and the latter 20 % greater than when the transformer is cold. For the purpose of calculations we require to know the number of turns on the primary and secondary circuits, represented by N_1 and N_2; the resistances of the primary and secondary circuits, represented by R_1 and R_2; the volume (V) and weight (W) of the iron core; and the mean length (L) and section (S) of the magnetic section. The hysteresis loss of the iron reckoned in watts per lb per 100 cycles of magnetization per second and at a maximum flux density of 2500 C.G.S. units should also be determined.

Testing.

The experimental examination of a transformer involves the measurement of the efficiency, the iron core loss, and the secondary drop; also certain tests as to insulation and heating, and finally an examination of the relative phase position and graphic form of the various periodic quantities, currents and electromotive forces taking place in the transformer. The efficiency is best determined by the employment of a properly constructed wattmeter (see WATTMETER). The transformer T (fig. 5) should be so arranged that, if a constant potential transformer, it is supplied with its normal working pressure at the primary side and with a load which can be varied, and which is obtained either by incandescent lamps, L, or resistances in the secondary circuit. A wattmeter, W, should be placed with its series coil, Se, in the primary circuit of the transformer, and its shunt coil, Sh, either across the primary mains in series, with a suitable non-inductive resistance, or connected to the secondary circuit of another transformer, T^1, called an *auxiliary transformer*, having its primary terminals connected to those of the transformer under test. In the latter case one or more incandescent lamps, L, may be connected in series with the shunt coil of the wattmeter so as to regulate the current passing through it. The current through the series coil of the wattmeter is then the same as the current through the primary circuit of the transformer under test, and the current through the shunt coil of the wattmeter is in step with, and proportional to, the primary voltage of the transformer. Hence the wattmeter reading is proportional to the mean power given up to the transformer. The wattmeter can be standardized and its scale reading interpreted by replacing the transformer under test by a non-inductive resistance or series of lamps, the power absorption of which is measured by the product of the amperes and volts supplied to it. In the secondary circuit of the transformer is placed another wattmeter of a similar kind, or, if the load on the secondary circuit is non-inductive, the secondary voltage and the secondary current can be measured with a proper alternating current ammeter, A_2, and voltmeter, V_2, and the product of these readings taken as a measure of the power given out by the transformer. The ratio of the powers, namely, that given out in the external secondary circuit and that taken in by the primary circuit, is the efficiency of the transformer.

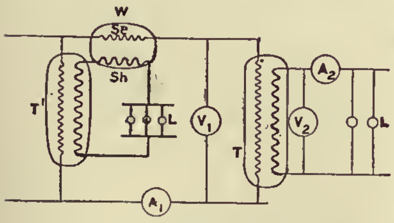

FIG. 5.—Arrangement for Testing Transformers.

In testing large transformers, when it is inconvenient to load up the secondary circuit to the full load, a close approximation to the power taken up at any assumed secondary load can be obtained by adding to the value of this secondary load, measured in watts, the iron core loss of the transformer, measured at no load, and the copper losses calculated from the measured copper resistances when the transformer is hot. Thus, if C is the iron core loss in watts, measured on open secondary circuit, that is to say, is the power given to the transformer at normal frequency and primary voltage, and if R_1 and R_2 are the primary and secondary circuit resistances when the transformer has the temperature it would have after running at full load for two or three hours, then the efficiency can be calculated as follows: Let O be the nominal value of the full secondary output of the transformer in watts, V_1 and V_2 the terminal voltages on the primary and secondary side, N_1 and N_2 the number of turns, and A_1 and A_2 the currents for the two circuits; then O/V_2 is the full load secondary current measured in amperes, and N_2N_1 multiplied by O/V_2 is to a sufficient approximation the value of the corresponding primary current. Hence O^2R_2/V_2^2 is the watts lost in the secondary circuit due to copper resistance, and $O^2R_1N_2^2/V_2^2N_1^2$ is the corresponding loss in the primary circuit. Hence the total power loss in the transformer (=L) is such that

$$L = C + \frac{O^2}{V_2^2}R_2 + \left(\frac{N_2}{N_1}\right)^2 \frac{O^2}{V_2^2}R_1 = C + (R_2 + R_1a^2)O^2/V_2^2.$$

Therefore the power given up to the transformer is O+L, and the efficiency is the fraction O/(O+L) expressed as a percentage. In this manner the efficiency can be determined with a considerable degree of accuracy in the case of large transformers without actually loading up the secondary circuit. The secondary drop, however, can only be measured by loading the transformer up to full load, and, while the primary voltage is kept constant, measuring the potential difference of the secondary terminals, and comparing it with the same difference when the transformer is not loaded. Another method of testing large transformers at full load without supplying the actual power is by W. E. Sumpner's differential method, which can be done when two equal transformers are available (see Fleming, *Handbook for the Electrical Laboratory and Testing Room*, ii. 602).

Ageing.

No test of a transformer is complete which does not comprise some investigation of the "ageing" of the core. The slow changes which take place in the hysteretic quality of iron when heated, in the case of certain brands, give rise to a time-increase in iron core loss. Hence a transformer which has a core loss, say, of 300 watts when new, may, unless the iron is well chosen, have its core loss increased from 50 to 300 % by a few months' use. In some cases specifications for transformers include fines and deductions from price for any such increase; but there has in this respect been great improvement in the manufacture of iron for magnetic purposes, and makers are now able to obtain supplies of good magnetic iron or steel with non-ageing qualities. It is always desirable, however, that in the case of large sub-station transformers tests should be made at intervals to discover whether the core loss has increased by ageing. If so, it may mean a very considerable increase in the cost of magnetizing power. Consider the case of a 30-kilowatt transformer connected to the mains all the year round; the normal core loss of such a transformer should be about 300 watts, and therefore, since there are 8760 hours in the year, the total annual energy dissipated in the core should be 2628 kilowatt hours. Reckoning the value of this electric energy at only one penny per unit, the core loss costs £10, 19s. per annum. If the core loss becomes doubled, it means an additional annual expenditure of nearly £11. Since the cost of such a transformer would not exceed £100, it follows that it would be economical to replace it by a new one rather than continue to work it at its enhanced core loss.

In Great Britain the sheet steel or iron alloy used for the transformer cores is usually furnished to specifications which state the maximum hysteresis loss to be allowed in it in watts per lb (avoirdupois) at a frequency of 50, and at a maximum flux-density during the cycle of 4000 C.G.S. units. When plates having a thickness t mils are made up into a transformer core, the total energy loss in the core due to hysteresis and eddy current loss when worked at a frequency n and a maximum flux-density during the cycle B is given by the empirical formulae

$$T = \cdot 0032nB^{1\cdot 55}10^{-7} + (tnB)^2 10^{-16},$$

or

$$T^1 = 0\cdot 88nB_1^{1\cdot 55}10^{-9} + 1\cdot 4(t_1 nB_1)^2 10^{-10},$$

where T stands for the loss per cubic centimetre, and T_1 for the same in watts per pound of iron core, B for the maximum flux-density in lines per square centimetre, and B_1 for the same in lines per square inch, t for the thickness of the plates in thousandths of an inch (mils), and t_1 for the same in inches. The hysteresis loss varies as some power near to 1·6 of the maximum flux-density during the cycle as shown by Steinmetz (see ELECTROMAGNETISM). Since the hysteresis loss varies as the 1·6th power of the maximum flux-density during the cycle (B max.), the advantages of a low flux-density are evident. An excessively low flux-density increases, however, the cost of the core and the copper by increasing the size of the transformer. If the form factor (f) of the primary voltage curve is known, then the maximum value of the flux-density in the core can always be calculated from the formula $B = E_1/4fnSN_1$, where E is the R.M.S. value of the primary voltage, N_1 the primary turns, S the section of the core, and n the frequency.

Curve Tracing. The study of the processes taking place in the core and circuits of a transformer have been greatly facilitated in recent years by the improvements made in methods of observing and recording the variation of periodic currents and electromotive forces. The original method, due to Joubert, was greatly improved and employed by Ryan, Bell, Duncan and Hutchinson, Fleming, Hopkinson and Rosa, Callendar and Lyle; but the most important improvement was the introduction and invention of the oscillograph by Blondel, subsequently improved by Duddell, and also of the ondograph of Hospitalier (see OSCILLOGRAPH). This instrument enables us, as it were, to look inside a transformer, for which it, in fact, performs the same function that a steam engine indicator does for the steam cylinder.[1] Delineating in this way the curves of primary and secondary current and primary and secondary electromotive forces, we get the following result: Whatever may be the form of the curve of primary terminal potential difference, or primary voltage, that of the secondary voltage or terminal potential difference is an almost exact copy, but displaced 180° in phase. Hence the alternating current transformer reproduces on its secondary terminals all the variations of potential on the primary, but changed in scale. The curve of primary current when the transformer is an open secondary circuit is different in form and phase, lagging behind the primary voltage curve (fig. 6); but if the transformer is loaded up on its secondary side, then the primary current curve comes more into step with the primary voltage curve. The secondary current curve, if the secondary load is non-inductive, is in step with the secondary voltage curve (fig. 7). These transformer diagrams yield much information as to the nature of the operations proceeding in the transformer.

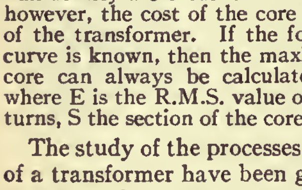

FIG. 6.—Transformer Curves at no load.

e_1, Primary voltage curve; i_1, Primary current curve; e_2, Secondary voltage curve.

[1] For a useful list of references to published papers on alternating current curve tracing, see a paper by W. D. B. Duddell, read before the British Association, Toronto, 1897; also *Electrician* (1897), xxxix. 636; also *Handbook for the Electrical Laboratory and Testing Room* (J. A. Fleming), i. 407.

The form of the curve of primary current at no secondary load is a consequence of the hysteresis of the iron, combined with the fact that the form of the core flux-density curves of the transformer is always not far removed from a simple sine curve. If e_1 is at any moment the electromotive force, i_1 the current on the primary circuit, and b_1 is the flux-density in the core, then we have the fundamental relation $e_1 = R_1 i_1 + SN_1\ db_1/dt$, where R_1 is the resistance of the primary, and N_1 the number of turns, and S is the cross-section of the core. In all modern closed circuit transformers the quantity $R_1 i_1$ is very small compared with the quantity $SNdb/dt$ except at one instant during the phase, and in taking the integral of the above equation, viz. in finding the value of $\int e_1 dt$, the integral of the first term on the right-hand side may be neglected in comparison with the second. Hence we have approximately $b_1 = (SN_1)^{-1}\int e_1 dt$. In other words, the value of the flux-density in the core is obtained by integrating the area of the primary voltage curve. In so doing the integration must be started from the time point through which passes the ordinate bisecting the area of the primary voltage curve. When any curve is formed such that its ordinate y is the integral of the area of another curve, viz. $y = \int y^1 dx$, the first curve is always smoother and more regular in form than the second. Hence the process above described when applied to a complex periodic curve, which can by Fourier's theorem be resolved into a series of simple periodic curves, results in a relative reduction of the magnitude of the higher harmonics compared with the fundamental term, and hence a wiping out of the minor irregularities of the curve. In actual practice the curve of electromotive force of alternators can be quite sufficiently reproduced by employing three terms of the expansion, viz. the first three odd harmonics, and the resulting flux-density curve is always very nearly a simple sine curve.

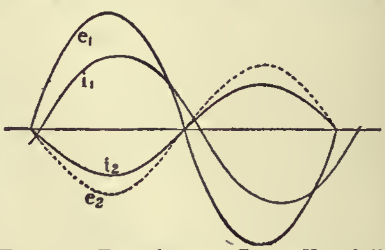

FIG. 7.—Transformer Curves at full load.

e_1, Primary voltage curve; i_1, Primary current curve; e_2, Secondary voltage curve; i_2, Secondary current curve.

We have then the following rules for predetermining the form of the current curve of the transformer at no load, assuming that the hysteresis curve of the iron is given, set out in terms of flux-density and ampere-turns per centimetre, and also the form of the curve of primary electromotive force. Let the time base line be divided up into equal small elements. Through any selected point draw a line perpendicular to the base line. Bisect the area enclosed by the curve representing the half wave of primary electromotive force and the base line by another perpendicular. Integrate the area enclosed between the electromotive force curve and these two perpendicular lines and the base. Lastly, set up a length on the last perpendicular equal to the value of this area divided by the product of the cross-section of the core and the number of primary turns. The resulting value will be the core flux-density b at the phase instant corresponding. Look out on the hysteresis loop the same flux-density value, and corresponding to it will be found two values of the magnetizing force in ampere-turns per centimetre, one the value for increasing flux-density and one for decreasing. An inspection of the position of the point of time selected on the time line will at once show which of these to select. Divide that value of the ampere-turns per centimetre by the product of the values of the primary turns and the mean length of the magnetic circuit of the core of the transformer, and the result gives the value of the primary current of the transformer. This can be set up to scale on the perpendicular through the time instant selected. Hence, given the form of the primary electromotive force curve and that of the hysteresis loop of the iron, we can draw the curves representing the changes of flux-density in the core and that of the corresponding primary current, and thus predict the root-mean-square value of the magnetizing current of the transformer. It is therefore possible, when given the primary electromotive force curve and the hysteresis curve of the iron, to predetermine the curves depicting all the other variables of the transformer, provided that the magnetic leakage is negligible.

Elementary Theory. The elementary theory of the closed iron circuit transformer may be stated as follows: Let N_1, N_2 be the turns on the primary and secondary circuits, R_1 and R_2 the resistances, S the section of the core, and b_1 and b_2 the co-instantaneous values of the flux-density just inside the primary and secondary windings. Then, if i_1 and i_2 and e_1 and e_2 are the primary and secondary currents and potential differences at the same instant, these quantities are connected by the equations

$$e_1 = R_1 i_1 + SN_1 \frac{db_1}{dt},\ e_2 = SN_2 \frac{db_2}{dt} - R_2 i_2.$$

Hence, if $b_1 = b_2$, and if $R_1 i_1$ is negligible in comparison with $SN_1 db/dt$, and $i = 0$, that is, if the secondary circuit is open, then $e_1/e_2 = N_1/N_2$, or the transformation ratio is simply the ratio of the windings. This, however, is not the case if b_1 and b_2 have not the same value; in other words, if there is magnetic leakage. If the magnetic leakage can be neglected, then the resultant magnetizing force, and therefore the iron core loss, is constant at all loads. Accordingly, the relation between the primary current (i_1), the secondary current (i_2), and the magnetizing current (i), or primary current at no load, is given by the equation $N_1 i_1 - N_2 i_2 = N_1 i$. Then, writing b for the instantaneous value of the flux-density in the core, everywhere supposed to be the same, we arrive at the identity

$$e_1 i_1 = e_2 i_2 + (R_1 i_1^2 + R_2 i^2) + S\frac{db}{dt}(N_1 i_1 - N_2 i_2).$$

This equation merely expresses the fact that the power put into the transformer at any instant is equal to the power given out on the secondary side together with the power dissipated by the copper losses and the constant iron core loss.

The efficiency of a transformer at any load is the ratio of the mean value, during the period, of the product $e_1 i_1$ to that of the product $e_2 i_2$. The efficiency of an alternating current transformer is a function of the form of the primary electromotive force curve. Experiment has shown[1] that if a transformer is tested for efficiency on various alternators having electromotive force curves of different forms, the efficiency values found at the same secondary load are not identical, those being highest which belong to the alternator with the most peaked curve of electromotive force, that is, the curve having the largest *form factor.* This is a consequence of the fact that the hysteresis loss in the iron depends upon the manner in which the magnetization (or what here comes to the same thing, the flux-density in the core) is allowed to change. If the primary electromotive force curve has the form of a high peak, or runs up suddenly to a large maximum value, the flux-density curve will be more square-shouldered than when the voltage curve has a lower form factor. The hysteresis loss in the iron is less when the magnetization changes its sign somewhat suddenly than when it does so more gradually. In other words, a diminution in the form factor of the core flux-density curve implies a diminished hysteresis loss. The variation in core loss in transformers when tested on various forms of commercial alternator may amount to as much as 10%. Hence, in recording the results of efficiency tests of alternating current transformers, it is always necessary to specify the form of the curve of primary electromotive force. The power factor of the transformer or ratio of the true power absorption at no load, to the product of the R.M.S. values of the primary current and voltage, and also the secondary drop of the transformer, vary with the form factor of the primary voltage curve, being also both increased by increasing the form factor. Hence there is a slight advantage in working alternating current transformers off an alternator giving a rather peaked or high maximum value electromotive force curve. This, however is disadvantageous in other ways, as it puts a greater strain upon the insulation of the transformer and cables. At one time a controversy arose as to the relative merits of closed and open magnetic circuit transformers. It was, however, shown by tests made by Fleming and by Ayrton on Swinburne's "Hedgehog" transformers, having a straight core of iron wires bristling out at each end, that for equal secondary outputs, as regards efficiency, open as compared with closed magnetic circuit transformers had no advantage, whilst, owing to the smaller power factor and consequent large R.M.S. value of the magnetizing current, the former type had many disadvantages (see Fleming, "Experimental Researches on Alternate Current Transformers," *Journ. Inst. Elec. Eng.*, 1892).

Magnetic Leakage. The discussion of the theory of the transformer is not quite so simple when magnetic leakage is taken into account. In all cases a certain proportion of the magnetic flux linked with the primary circuit is not linked with the secondary circuit, and the difference is called the magnetic leakage. This magnetic leakage constitutes a wasted flux which is non-effective in producing secondary electromotive force. It increases with the secondary current, and can be delineated by a curve on the transformer diagram in the following manner. The curves of primary and secondary electromotive force, or terminal potential difference and current, are determined experimentally, and then two curves are plotted on the same diagram which represent the variation of $(e_1 - R_1 i_1)/N_1$ and $(e_2 + R_2 i_2)/N_2$; these will represent the time differentials of the total magnetic fluxes Sb_1 and Sb_2 linked respectively with the primary and secondary circuits. The above curves are then progressively integrated, starting from the time point through which passes the ordinate bisecting the area of each half wave, and the resulting curves plotted to express by their ordinates Sb_1 and Sb_2. A curve is then plotted whose ordinates are the differences $Sb_1 - Sb_2$, and this is the curve of magnetic leakage.

The existence of magnetic leakage can be proved experimentally by a method due to Mordey, by placing a pair of thermometers, one of mercury and the other of alcohol, in the centre of the core aperture. If there is a magnetic leakage, the mercury bulb is heated not only by radiant heat, but by eddy currents set up in the mercury, and its rise is therefore greater than that of the alcohol thermometer. The leakage is also determined by observing the secondary voltage drop between full load and no load, and deducting from it the part due to copper resistance; the remainder is the drop due to leakage. Thus if V_2 is the secondary voltage on open circuit, and V_2^1 that when a current A_2 is taken out of the transformer, the leakage drop v is given by the equation

$$v = (V_2 - V_2^1) - \{R_2 A_2 + R_1 A_2 (N_2/N_1)^2\}.$$

The term in the large bracket expresses the drop in secondary voltage due to the copper resistance of the primary and secondary circuits.

In drawing up a specification for an alternating current transformer, it is necessary to specify that the maximum secondary drop between full and no load to be allowed shall not exceed a certain value, say 2% of the no-load secondary voltage; also that the iron core loss as a percentage of the full secondary output shall not exceed a value, say, of 1% after six months' normal work.

Transformer Design. In the design of large transformers one of the chief points for attention is the arrangement for dissipating the heat generated in their mass by the copper and iron losses. For every watt expended in the core and circuit, a surface of 3 to 4 sq. in. must be allowed, so that the heat may be dissipated. In large transformers it is usual to employ some means of producing a current of air through the core to ventilate it. In these, called *air-blast transformers*, apertures are left in the core by means of which the cooling air can reach the interior portions. This air is driven through the core by a fan actuated by an alternating current motor, which does not, however, take up power to a greater extent than about $\frac{1}{4}$ or $\frac{1}{10}$% of the full output of the transformer, and well repays the outlay.

In some cases transformers are *oil-insulated*, that is to say, included in a cast-iron box which is filled in with a heavy insulating oil. For this purpose an oil must be selected free from mineral acids and water: it should be heated to a high temperature before use, and tested for dielectric strength by observing the voltage required to create a spark between metal balls immersed in it at a distance of 1 millimetre apart. Oils, however, are inferior in dielectric strength or spark-resisting power to solid dielectrics, such as micanite, ebonite, &c., as shown by the above table of dielectric strengths (see T. Gray, *Phys. Rev.*, 1898, p. 199).

Material.	Dielectric strength in kilowatts per centimetre.	Material.	Dielectric strength in kilowatts per centimetre.
Glass	285	Lubricating oil . .	83
Ebonite	538	Linseed oil . . .	67
Indiarubber . . .	492	Cotton-seed oil. .	57
Mica	2000	Air film ·02 cm. thick	27
Micanite	4000	Air film 1·6 cm. thick	48

Polyphase Transformers are appliances of similar construction to the single-phase transformers already described, but modified so as to enable them to transform two or more phase-related primary alternating currents into similar secondary currents. Thus, a three-phase transformer may be constructed with a core, as shown in fig. 8. Each core leg is surrounded with a primary coil, and these are joined up either in star or delta fashion, and connected to the three or four line wires. The secondary circuits are then connected in a similar fashion to three or four secondary lines. In the case of two-phase transmission with two separate pairs of leads, single-phase transformers may be

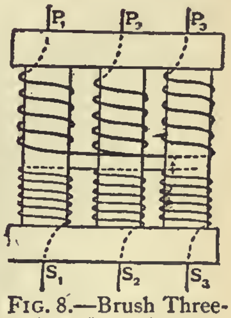

FIG. 8.—Brush Three-phase Transformer.

[1] See Dr G. Roessler, *Electrician* (1895), xxxvi. 150; Beeton, Taylor and Barr, *Journ. Inst. Elec. Eng.* xxv. 474; also J. A. Fleming, *Electrician* (1894), xxxiii. 580.

employed in each branch, but with two-phase three-wire supply, two-phase transformers must be supplied.

Phase Transformers are arrangements of static or rotary transformers intended to transform single-phase alternating currents into polyphase currents. An important system of phase transformation has been described by C. F. Scott.[1] It is known that if two alternating electromotive forces differing in phase are connected in series, the resulting electromotive force will in general differ in phase and value from either of the components. Thus, if two alternating electromotive forces differing 90° in phase, and having magnitudes in the ratio of $1 : \sqrt{3}$, are connected in series, the resulting electromotive force will have a magnitude represented by 2, and the three can be represented by the sides of a triangle which is half an equilateral triangle. If then a two-phase alternator, D (fig. 9), provides two-phase currents, and if the two circuits are connected, as shown, to a pair of single-phase transformers, T_1 and T_2, we can obtain three-phase alternating currents from the arrangement. The primaries of both transformers are the same. The secondary circuit of one transformer, T_2, has, say, 100 turns, and a connexion is made to its middle point O, and this is connected to the secondary of the other transformer which has 87 ($=50\sqrt{3}$) turns. From the points A, B, C we can then tap off three-phase alternating currents. The advantages of the Scott system are that we can transform two-phase alternating currents into three-phase for transmission, and then by a similar arrangement retransform back again into two-phase for use. In this manner an economy of 25% in copper is effected, for instead of four transmission lines we have only three. The system adapts itself for the transmission of currents both for power in driving three-phase motors and for working incandescent lamps. A somewhat similar system has been designed by C. P. Steinmetz for producing three-phase currents from single-phase (see *Electrician*, xliii. 236). When a number of alternating electromotive forces are maintained in a closed circuit, the sum of all must be zero, and may be represented by the sides of a closed polygon. The fundamental principle of Mr Steinmetz's invention consists in so choosing the number of these electromotive forces that the polygon must remain stable. Thus, if three single-phase alternators are driven independently at constant speed and excitation, and if they are joined in series, then three wires led away from the junction points will provide three-phase currents to a system from which lamps and motors may be worked.

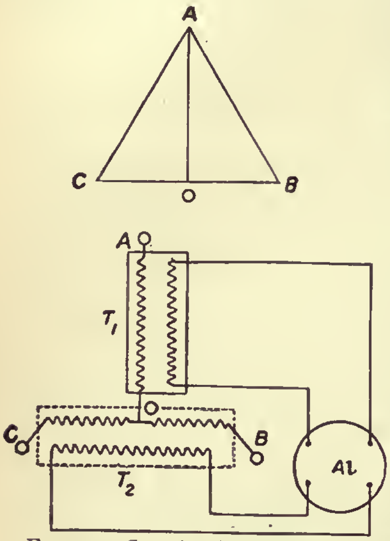

FIG. 9.—Scott's Arrangement for Transformation of Two-phase to Three-phase Currents.

Reference must be made to the continuous current transformer. The conversion of a continuous current supplied, say, at 100 volts, into one having an electromotive force of 10 volts, can of course be achieved by coupling together on the same bedplate a suitable electric motor and a dynamo. The combination is called a *motor-dynamo set*, and each machine preserves its own identity and peculiarity. The same result may, however, be accomplished by winding two separate armature circuits on one iron core, and furnishing each with its own commutator. The two circuits are interlaced or wound on together. An arrangement of this kind constitutes a *rotatory* or *rotary transformer*, or continuous current transformer. It has the advantage of greater cheapness and efficiency, because one field magnet serves for both armature windings, and there is only one armature core and one pair of bearings; moreover, no shift or lead of the brushes is required at various loads. The armature reactions of the two circuits annul each other. Machines of this description are self-starting, and can be constructed to take in primary current at high pressures, say 1000 to 2000 volts, and yield another larger current of much lower voltage, say 100 or 150 volts, for use with electric lamps. They are used in connexion with public electric supply by continuous current in many places.

Continuous Current Transformers.

Another important class of rotatory transformer is that also called a *rotatory converter*, by means of which continuous current is translated into alternating current of one-, two- or three-phase, or vice versa. The action of such an appliance may best be understood by considering the simple case of a Gramme ring armature (see DYNAMO) having, in addition to its commutator, a pair of insulated rings on its shaft connected with opposite ends of the armature winding (fig. 10). If such a ring is placed in a bipole field magnet, and if a pair of brushes make contact with the commutator C and another pair with the two rings called slip rings, S_1 S_2, and if continuous current at a constant voltage is supplied to the commutator side, then the armature will begin to revolve in the field, and from the brushes in contact with the slip rings we can draw off an alternating current. This reaches its maximum value when the points of contact of the rings with the armature circuit pass the axis of commutation, or line at right angles to the direction of the magnetic field, for it has at this moment a value which is double the steady value of the continuous current being poured into the armature. The maximum value of the electromotive force creating this alternating current is nearly equal to the electromotive force on the continuous current side. Hence if A is the maximum value of the continuous current put into the armature and V is the value of the brush potential difference on the continuous current side, then 2A is the maximum value of the outcoming alternating current and V is the maximum value of its voltage. Hence $2AV/2 = AV$ is the maximum value of the outcoming alternating current power, and if we neglect the loss in the armature for the moment, the power given out is equal to the power put in. Hence, assuming a simple harmonic law of variation, the effective value of the alternating current voltage is $V/\sqrt{2}$, and that of the alternating current is $2A\sqrt{2}$. This conclusion follows at once from the fact that the mean value of the square of a sine function is half its maximum value, and hence the R.M.S. value is $1/\sqrt{2}$ times the maximum value. The outcoming alternating current has its zero value at the instant when the ends of the diameter of the axis to which the rings are connected are in the direction of the magnetic field of the transformer. Hence the power output on the alternating current side varies from a maximum value AV to zero. The rotatory transformer thus absorbs continuous current power and emits it in a periodic form; accordingly, there is a continual storage and emission of energy by the armature, and therefore its kinetic energy is periodically varying during the phase. The armature is also creating a back-electromotive force which acts at some instants against the voltage driving the current into the armature and at others is creating an electromotive force that assists the external impressed voltage in driving a current through the alternating current side. If we put on another pair of insulated rings and connect them to points of the insulated diameter at right angles to the points of connexion of the first pair of rings, we can draw off another alternating current, the phase of which differs 90° from that of the first. Similarly, if we provide three rings connected to points removed 120° apart on the armature circuit, we can tap off a three-phase alternating current.

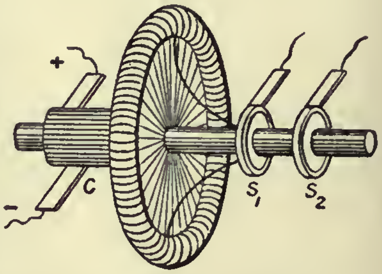

FIG. 10.—Rotary Converter, continuous to two-phase.

Returning to the case of the single-phase rotatory transformer, we may notice that at the instant when the outcoming alternating current is zero the armature is wholly engaged in absorbing power and is acting entirely as a motor. When the alternating current is a maximum, the armature on the other hand is acting as a generator and adds current to the current put into it. The ratio between the potential difference of the brushes on the continuous current side and the root-mean-square or effective value of the voltage between any pair of rings on the alternating current side is called the transformation ratio of the converter.

The following table, taken from a paper upon rotatory converters by S. P. Thompson (*Proc. Inst. Elec. Eng.*, November 1898), gives the voltage ratio or conversion ratio in the case of various forms of rotatory transformer:—

Number of slip rings.	Angle between points of connexions to armatures.	Type of current generated.	Voltage ratio.	Effective voltage on alternating current side as percentage of voltage on continuous current side.
2	180°	Single-phase	$\sqrt{2}:1$	70·71
3	120°	Three-phase	$2\sqrt{2}:\sqrt{3}$	61·23
4	90°	Two-phase	$\sqrt{2}:1$	70·71
4	90°	Four-phase	2:1	50
6	60°	Three-phase	$3\sqrt{3}:\sqrt{3}$	61·23
6	60°	Six-phase	$2\sqrt{2}:1$	35·35

[1] *Proceedings of the National Electric Light Association* (Washington, U.S.A., 1894); also *Electrician* (1894), xxxii. 640.

Neglecting the energy losses in the armature, and assuming that the continuous current side of the transformer is supplied with 100 amperes, the following table, also taken from a paper by S. P. Thompson, shows the effective value of the current on the alternating side put out into each line:—

Number of slip rings.	Angle between points of connexion to armature.	Type of current generated.	Effective current put out on each line in amperes.
2	180°	Single-phase	141·4
3	120°	Three-phase	94·3
4	90°	Two-phase	70·7
6	60°	Six-phase	47·2

It is obvious that the same results of conversion can be obtained by coupling together two separate machines on the same shaft; thus we might obtain a single-phase alternating current from a continuous current by coupling together mechanically a continuous current motor and a single-phase alternator. Such a combination is generally called a *motor-dynamo*. In this case there are two field magnets and two separate armatures, and the hysteresis eddy current and copper losses are all in duplicate. If, however, the same armature winding is made to serve both purposes, the resulting machine is called a *rotatory* or *rotary converter*. In the former combination the brushes of the continuous current part require to be set with the usual lead or lag according as that part is generator or motor, but in the latter the armature reactions nearly annul each other, and lead or lag is no longer necessary.

Rectifiers.

Rectifiers are devices for transforming an alternating (generally single-phase) current into a continuous but pulsatory current. They may shortly be described as appliances for separating out each alternate current flux in an alternating current. An immense number of more or less imperfect methods of doing this have been proposed, and here we shall describe two which may be called respectively the mechanical and the electrolytic methods. Of the first class a good example is the Ferranti rectifier (fig. 11). This consists of a synchronous alternating current motor which is started up and driven in step with the alternator supplying the current. The

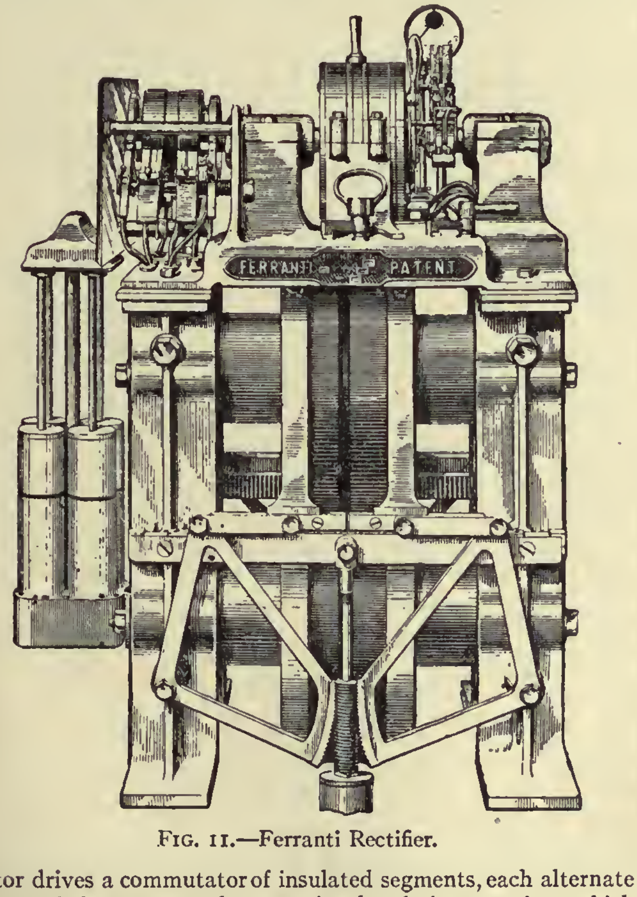

Fig. 11.—Ferranti Rectifier.

motor drives a commutator of insulated segments, each alternate segment being connected to two insulated rings, against which press a pair of brushes. Another pair of brushes, so adjusted as to be in contact simultaneously with a pair of adjacent commutator segments, are in connexion with the alternator supplying the current to be commutated. The insulated rings are in connexion with the external circuit. It will easily be seen that when the commutator revolves at proper speed the currents delivered from the insulated rings are unidirectional. The Ferranti rectifier is much employed for rectifying alternating current for arc lighting purposes. With this object it is associated with a constant current transformer which converts alternating current supplied at constant potential to one supplied at constant current. This is achieved by taking advantage of the repulsive force existing between the primary and secondary circuits of a transformer. These are wound separately, and so balanced that any increase in the current presses them away from each other and so reduces the secondary current to normal value. Such an appliance is useful for rectifying currents up to 10 or 15 amperes.

The electrolytic rectifier is based upon the fact that if plates of aluminium and carbon are placed in an electrolyte, say a solution of alum or dilute acids which yield oxygen on electrolysis, it is found that a current can be sent through the liquid from the carbon to the aluminium, but that great counter-electromotive force is created to a current in the opposite direction. Grätz and Pollak (*Elektrotechnische Zeitschrift*, 1897, 25, p. 359), taking advantage of this fact, have constructed a rectifying arrangement by arranging two series of carbon aluminium (CAl) cells with alum or hydro-potassic phosphate solution as electrolyte. In one set the order of the plates is (CAl), (CAl), &c., and in the other series (AlC), (AlC), counting from the same end. These series being connected in parallel, it follows that if an alternating current is sent through the parallel series all the currents in one direction pass through one battery and all those in the opposite direction through the other. Thus the constituents of the alternating current are separated out. By using very large cells so as to reduce the internal resistance, an efficiency of 95% is said to be obtained.

Theory of Electrolytic Rectifier.

There are many points in the operation of the electrolytic rectifier which have as yet been imperfectly explained. The action of the aluminium electrolytic rectifier, consisting as it does of an aluminium plate and a lead or carbon plate placed in an aqueous electrolyte, is to oppose a great obstruction to a current passing out of the aluminium plate, but little or no obstruction to the current passing into the aluminium plate, especially if the aluminium has been subjected to a previous treatment called *formation*. This unilateral conductivity is dependent on a certain voltage or potential difference between the plates not being exceeded, but within these limits a plate of carbon and aluminium placed in a solution, say of hydro-sodic phosphate, acts as an electrical *valve*, allowing current to pass in one direction but not in another. An examination of the aluminium plate after it has been so used shows that its appearance has changed and that its surface is covered by a thin film, the thickness of which varies with the electrolyte and the time of formation. After a certain period of use this film is seen as a grey, dull coating traversed by dark lines. It is impossible that the unilateral conductivity can be due to a true electrolytic polarization, because we know of no polarization of this latter kind which exceeds three volts, and the film can be made to resist the flow of a current under an electromotive force of 140 to 200 volts. The resistance of this film has been measured and found to be very high, so high as to be practically an insulation. Light was thrown upon the subject by F. Kohlrausch's discovery of the polarization capacity of metallic electrodes, and this discovery was applied to develop the theory of the aluminium cell by Streintz (1888), Scott (1899) and others.

This theory was expounded by K. Norden (*Electrician*, xlviii. 107). According to this view, the deposit covering the aluminium electrode forms the dielectric of a condenser. One plate of the condenser is formed by the aluminium plate and the other by an opposite layer of electrically-charged ions in the electrolyte. The dielectric film on the aluminium having been formed, the electromotive force of the circuit then charges the resulting condenser to the value of its own voltage, but immediately the impressed electromotive force is removed this condenser discharges itself. This condenser theory receives support from the behaviour of the aluminium cell when placed in the circuit of an alternating current dynamo, for it is found that in these circumstances the current through the cell is in advance in phase of the difference of potential. The question then arises, What is the nature of this insulating film? The first discoverer of the phenomenon (Buff) considered it to consist of silicon. Later Professor Beetz disproved this by experiment, and, with many others, assumed that a sub-oxide of aluminium was formed; but this has never been demonstrated in a satisfactory manner. By forming a sufficient quantity of the film Dr K. Norden was able to obtain sufficient of the material to make a chemical analysis, and this revealed the fact that it consists of normal aluminium hydroxide, $Al_2(OH)_6$.

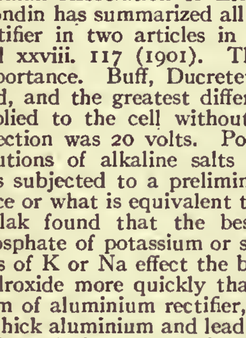
According to the facts above stated, one wave of the alternating current produces the insulating film by converting the surface of the aluminium into hydroxide, practically, therefore, blocking its own path very quickly by the creation of this film. If, then, the electromotive force reverses its direction the current immediately flows. According to Dr Norden, the rapid removal of the insulating film is due to the action of the electrolyte corroding or dissolving the weak points in the coating and thus breaking down its insulating power. The insulating film is therefore a conductor in one direction, but when the current is reversed and flows out of the aluminium plate the insulating film is renewed and is continually being repaired and kept in order. Thus different electrolytes yield aluminium valves having very different efficiencies.

Rectifying cells have been made by Pollak which will bear a voltage of over 140 volts, and which are said to have an efficiency of 75%. The plates, however, must be removed when not in use, otherwise the film of hydroxide is destroyed by the electrolyte. One great practical difficulty in connexion with the aluminium rectifier is the tendency to heat in working.

The historical development of the discovery of this unilateral conductivity of an electrolytic cell with an aluminium electrode is as follows. The effect was first noticed by Buff in 1857, but was not applied technically until 1874, when Ducretet employed it in telegraphy. Beret in 1877 and Streintz in 1887 discussed the theory of the cell and sought for an explanation. In 1891 Hutin and Leblanc, in their study of alternating current, showed its uses in rectifying an alternating current. Pollak and Grätz laboured to give it a practically useful form. Pollak took out patents in 1895, and made a communication to the Academy of Sciences in Paris in June 1897; and Grätz presented a memoir at a meeting of the German Association of Electrochemists in Munich in 1897. M. Blondin has summarized all the work so far done on the aluminium rectifier in two articles in *L'Éclairage électrique* (1898), xiv. 293, and xxviii. 117 (1901). The choice of an electrolyte is of great importance. Buff, Ducretet and Grätz employed dilute sulphuric acid, and the greatest difference of potential which could then be applied to the cell without breaking down its insulation in one direction was 20 volts. Pollak in 1896 found that when aqueous solutions of alkaline salts were used, and when the aluminium was subjected to a preliminary formation, the back electromotive force or what is equivalent to it could be raised to 140 or 200 volts. Pollak found that the best results were given by the use of phosphate of potassium or sodium. It appears, therefore, that the ions of K or Na effect the breaking down of the film of aluminium hydroxide more quickly than the ion of hydrogen. The practical form of aluminium rectifier, according to Pollak, consists of plates of thick aluminium and lead placed in a large deep glass vessel filled with a solution of potassium hydrogen phosphate.

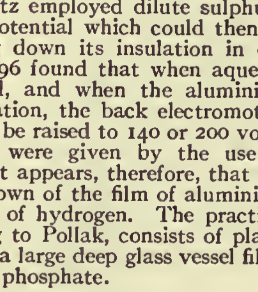
Nodon Valve.

In 1899 Albert Nodon of Paris began experimenting with an electric rectifier which is now on a commercial footing. It is known as the Nodon electric valve, and it is claimed that it will give an efficiency of 75 to 80% when used to transform single or polyphase currents into continuous currents. In the form used for transforming single-phase currents the valve is made up of 4 cells, each consisting of an iron cylinder with an insulating plug at the bottom through which is passed a cylinder formed of an alloy of zinc and aluminium. This cylinder is concentric with the iron tube and provided with a terminal at the lower end. The cell is filled with a saturated solution of ammonium phosphate, and a non-conducting shielding tube can be slid over the aluminium electrode to alter the exposed area.



(From the *Electrical Times*, by permission.)

Fig. 12.—Section through Nodon Valve.



(From the *Electrical Times*, by permission.)

Fig. 13.—Method of connecting the cells.

The valve is shown in section in fig. 12, and the 4 cells are arranged in a Wheatstone's Bridge fashion, as shown in fig. 13. A and A^1 are the terminals to which the alternating current is supplied, C and C^1 the terminals from which the continuous current is drawn off. The electrolytic actions which take place in the cells are as follows: When the alternating current passes in the positive direction from the zinc-aluminium cylinder to the iron cylinder there is formed instantly on the former a film of aluminium hydroxide; this film, presenting an enormous resistance, opposes the passage of the current. On the other hand, if the current passes in the opposite direction the film is reduced instantly and the current now flows. When used with polyphase currents the valve comprises as many times two cells as there are wires in the distribution. The cells must stand a pressure varying from 50 to 140 volts, and for higher pressures two or more valves in series are employed.

The aluminium-iron electrolytic rectifier is not suitable for the rectification of very high frequency currents, because the chemical actions on which it depends involve a time element.

Vacuum or Vapour Rectifiers.

It was, however, discovered by J. A. Fleming that an oscillation valve could be constructed for rectifying electrical oscillations, as follows (see *Proc. Roy. Soc. Lond.*, 1905, 74, p. 476): In a glass bulb similar to that of an incandescent lamp a carbon filament is fixed. Around the carbon filament, but not touching it, is placed a cylinder of nickel connected to an external terminal by means of platinum wire sealed through the glass. If the carbon filament is made incandescent by an insulated battery (and for this purpose it is convenient to have the filament adjusted to be fully incandescent at a pressure of about 12 volts), then the space between the incandescent filament and the embracing cylinder possesses a unilateral conductivity such that negative electricity can pass from the incandescent filament to the cylinder but not in the opposite direction. Hence if the negative terminal of the filament and the terminal attached to the cylinder are connected to an oscillation transformer (see Induction Coil) which supplies a high frequency alternating oscillatory current, the flow of electricity in one direction is cut out and the oscillatory current is therefore converted into a continuous current. Such valves have been employed by Fleming in connexion with wireless telegraphy. Wehnelt discovered that if a platinum wire was covered with oxide of barium or any of the oxides of rare earth metals, it possessed in the same manner, when used in a valve of the above type, an even greater power than incandescent carbon. The explanation of this action is to be sought for in the fact that incandescent carbon in a vacuum or incandescent earthy oxides copiously emit negative electrons.

A rectifier dependent upon the peculiar qualities of mercury vapour has been devised by Cooper-Hewitt for the transformation of polyphase currents into continuous currents. The three-phase transformer is made as follows: A large glass bulb (see fig. 14) has four iron electrodes sealed through the walls as positive electrodes and a negative electrode consisting of a pool of mercury in the bottom of the bulb connected with platinum wires sealed through the glass; the bulb is highly exhausted and contains only mercury vapour. The three iron electrodes are connected to the terminals of a star-connected polyphase transformer and one of them to the positive pole of a continuous current starting current, the connexions being shown as in fig. 15. The mercury vapour is a non-conductor for low voltages, but if a sufficiently high voltage is placed on the mercury bulb by means of the continuous current it begins to conduct and if the three-phase current is then switched on the mercury vapour will allow the components of the three-phase current to pass when the mercury electrode is negative, not when it is positive. Hence for alternate current wave of the three-phase, supply is cut down and a continuous current can be drawn by the connexions as shown in fig. 15 for the purposes of supplying secondary batteries, arc lamps, &c.

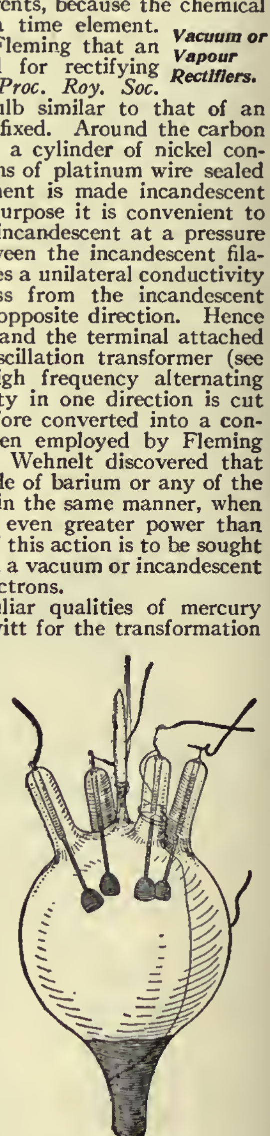


Fig. 14.
Cooper-Hewitt Rectifier.

Owing to the fact that the mercury vapour ceases to conduct when the electromotive force on it falls below a certain critical value the valve will not work with single-phase currents but will work with polyphase currents at all voltage from 100 to 1000 or more and can transform as much as 100 amperes. It is stated to have an efficiency of 88 to 89%. (See *The Electrician*, 1903, 50, p. 510.)

A mechanical polyphase rectifier or rotary devised by Bragstad and La Cour is described in *Der Kaskadenumformer*, by E. Arnold and J. L. La Cour, Stuttgart, 1904. It consists of a three-phase induction motor coupled direct to a continuous current dynamo, the armatures of the two machines being electrically connected so that the three-phase current created in the rotor of the induction

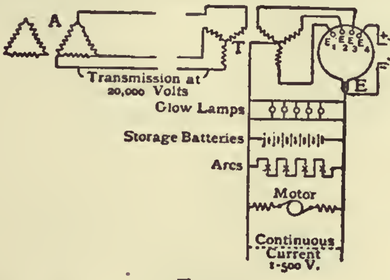

FIG. 15.

motor enters the continuous current armature and creates around it a rotary field. The connexions are such that the rotating field turns in a direction opposite to that in which the armature is turning, so that the field is stationary in space. From the continuous current armature can therefore be drawn off a continuous current and the device acts as a transformer of three-phase alternating current to a continuous current.

The ordinary induction coil (*q.v.*) may be regarded as the transformer for converting continuous current at low voltage into high voltage intermittent continuous current, but the difficulties of interrupting the primary current render it impossible to transform in this way more than a small amount of power. Where, however, high voltages are required, high potential transformers are used which are now built for the purpose of wireless telegraphy and the transformation of power to give secondary voltages up to 20,000, 30,000 or 60,000 volts. Transformers have even been built to give secondary voltages of half a million volts capable of giving a 14 in. spark in air. These machines, however, must be regarded as more physical laboratory instruments than appliances for technical work. For description of one such extra high potential transformer see H. B. Smith, on "Experiments on Transformers for Very High Potentials," *The Electrician* (1904), 54, p. 358. A transformer of this kind must invariably be an oil insulated transformer, as under extremely high voltage the air itself becomes a conductor and no solid insulator that can be put upon the wires is strong enough to stand the electric strain.

TRANSIT CIRCLE, or MERIDIAN CIRCLE, an instrument for observing the time of a star's passing the meridian, at the same time measuring its angular distance from the zenith. The idea of having an instrument (quadrant) fixed in the plane of the meridian occurred even to the ancient astronomers, and is mentioned by Ptolemy, but it was not carried into practice until Tycho Brahe constructed a large meridian quadrant. This instrument enabled the observer to determine simultaneously right ascension and declination, but it does not appear to have been much used for right ascension during the 17th century, the method of equal altitudes by portable quadrants or measures of the angular distance between stars with a sextant being preferred. These methods were, however, very inconvenient, which induced Römer to invent the transit instrument about 1690. It consists of a horizontal axis in the direction east and west resting on firmly fixed supports, and having a telescope fixed at right angles to it, revolving freely in the plane of the meridian. At the same time Römer invented the altitude and azimuth instrument for measuring vertical and horizontal angles, and in 1704 he combined a vertical circle with his transit instrument, so as to determine both co-ordinates at the same time. This latter idea was, however, not adopted elsewhere, although the transit instrument soon came into universal use (the first one at Greenwich was mounted in 1721), and the mural quadrant continued till the end of the century to be employed for determining declinations. The advantage of using a whole circle, as less liable to change its figure, and not requiring reversal in order to observe stars north of the zenith, was then again recognized by Ramsden, who also improved the method of reading off angles by means of a micrometer microscope as described below. The making of circles was shortly afterwards taken up by Troughton, who in 1806 constructed the first modern transit circle for Groombridge's observatory at Blackheath, but he afterwards abandoned the idea, and designed the mural circle to take the place of the mural quadrant. In the United Kingdom the transit instrument and mural circle continued till the middle of the 19th century to be the principal instrument in observatories, the first transit circle constructed there being that at Greenwich (mounted in 1850) but on the continent the transit circle superseded them from the years 1818–1819, when two circles by Repsold and by Reichenbach were mounted at Göttingen, and one by Reichenbach at Königsberg.[1] The firm of Repsold was for a number of years eclipsed by that of Pistor and Martins in Berlin, who furnished various observatories with first-class instruments, but since the death of Martins the Repsolds have again taken the lead, and have of late years made many transit circles. The observatories of Harvard College (United States), Cambridge and Edinburgh have large circles by Troughton and Simms, who also made the Greenwich circle from the design of Airy.[2]

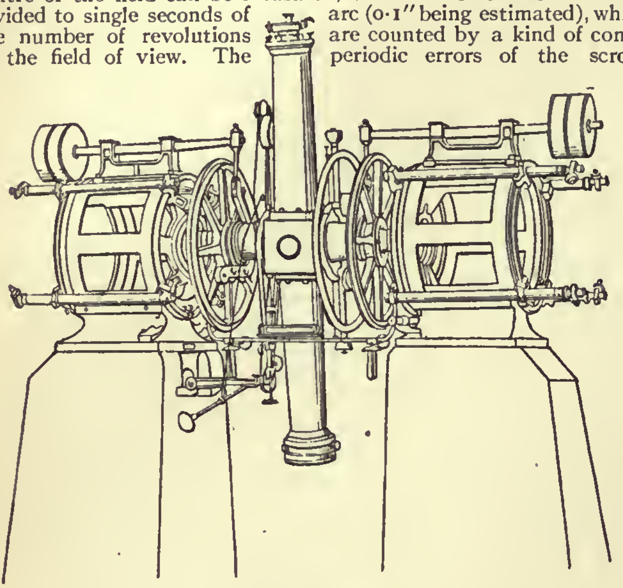
In the earliest transit instrument the telescope was not placed in the middle of the axis, but much nearer to one end, in order to prevent the axis from bending under the weight of the telescope. It is now always placed in the centre of the axis. The latter consists of one piece of brass or gun-metal with carefully turned cylindrical steel pivots at each end. Several recent instruments have been made entirely of steel, which is much more rigid than brass. The centre of the axis is shaped like a cube, the sides of which form the basis of two cones which end in cylindrical parts. The pivots rest on V-shaped bearings, either let into the massive stone or brick piers which support the instrument or attached to metal frameworks bolted on the tops of the piers. In order to relieve the pivots from the weight of the instrument, which would soon destroy their figure, the cylindrical part of each end of the axis is supported by a hook supplied with friction rollers, and suspended from a lever supported by the pier and counterbalanced so as to leave only about 10 ℔ pressure on each bearing. Near each end of the axis is attached a circle or wheel (generally of 3 or $3\frac{1}{2}$ ft. diameter) finely divided to 2′ or 5′ on a slip of silver let into the face of the circle near the circumference. The graduation is read off by means of microscopes, generally four for each circle at 90° from each other, as by taking the mean of the four readings the eccentricity and the accidental errors of graduation are to a great extent eliminated.[3] In the earlier instruments by Pistor and Martins the microscopes were fixed in holes drilled through the pier, but afterwards they let the piers be made narrower, so that the microscopes could be at the sides of them, attached to radial arms starting from near the bearings of the axis. This is preferable, as it allows of the temporary attachment of auxiliary microscopes for the purpose of investigating the errors of graduation of the circle, but the plan of the Repsolds and of Simms, to make the piers short and to let the microscopes and supports of the axis be carried by an iron framework, is better still, as no part of the circle is

[1] The most notable exception was the transit instrument and vertical circle of the Pulkovo observatory, specially designed by the elder Struve for fundamental determinations.

[2] This instrument differs in many particulars from others: the important principle of symmetry in all the parts (scrupulously followed in all others) is quite discarded; there is only one circle; and the instrument cannot be reversed. There is a similar instrument at the Cape observatory.

[3] On Reichenbach's circles there were verniers instead of microscopes, and they were attached to an alidade circle, the immovability of which was tested by a level.

exposed to radiation from the pier, which may cause strain and thereby change the angular distance between various parts of the circle. Each microscope is furnished with a micrometer screw, which moves a frame carrying a cross, or better two close parallel threads of spider's web, with which the distance of a division line from the centre of the field can be measured, the drum of the screw being divided to single seconds of arc (0·1″ being estimated), while the number of revolutions are counted by a kind of comb in the field of view. The periodic errors of the screw



Transit Circle.

must be investigated and taken into account, and care must be taken that the microscopes are placed and kept at such a distance from the circle that one revolution will correspond to 1′, the excess or defect (error of run) being determined from time to time by measuring standard intervals of 2′ or 5′ on the circle.

The telescope consists of two slightly conical tubes screwed to the central cube of the axis. It is of great importance that this connexion should be as firm and the tube as stiff as possible,[1] as the flexure of the tube will affect the declinations deduced from the observations. The flexure in the horizontal position of the tube may be determined by means of two collimators or telescopes placed horizontally in the meridian, north and south of the transit circle, with their object glasses towards it. If these are pointed on one another (through holes in the central tube of the telescope), so that the wire-crosses in their foci coincide, then the telescope, if pointed first to one and then to the other, will have described exactly 180°, and by reading off the circle each time the amount of flexure will be found. M. Loewy has constructed a very ingenious apparatus[2] for determining the flexure in any zenith distance, but generally the observer of standard stars endeavours to eliminate the effect of flexure in one of the following ways: either the tube is so arranged that eyepiece and object-glass can be interchanged, whereby the mean of two observations of the same star in the two positions of the object-glass will be free from the effect of flexure, or a star is not only observed directly (in zenith distance Z), but also by reflection from a mercury trough (in zenith distance $180°—Z$), as the mean result of the Z.D. of the direct and reflection observations, before and after reversing the instrument east and west, will only contain the terms of the flexure depending on $\sin 2Z$, $\sin 4Z$, &c. In order to raise the instrument a reversing carriage is provided which runs on rails between the piers, and on which the axis with circles and telescope can be raised by a kind of screw-jack, wheeled out from between the piers, turned exactly 180°, wheeled back, and gently lowered on its bearings.

The eye end of the telescope has in a plane through the focus a number of vertical and one or two horizontal wires (spider lines). The former are used for observing the transits of the stars, each wire furnishing a separate result for the time of transit over the middle wire by adding or subtracting the known interval between the latter and the wire in question. The intervals are determined by observing the time taken by a star of known declination to pass from one wire to the other, the pole star being best on account of its slow motion.[3] Instead of vertical wires, the eye end may be fitted with Repsold's self-registering micrometer with one movable wire to follow the star (see MICROMETER). The instrument is provided with a clamping apparatus, by which the observer, after having beforehand set to the approximate declination of a star, can clamp the axis so that the telescope cannot be moved except very slowly by a handle pushing the end of a fine screw against the clamp arm, which at the other side is pressed by a strong spring. By this slow motion, the star is made to run along one of the horizontal wires (or if there are two close ones, in the middle between them), after which the microscopes are read off. A movable horizontal wire or declination-micrometer is also often used. The field or the wires can be illuminated at the observer's pleasure; the lamps are placed at some distance from the piers in order not to heat the instrument, and the light passes through holes in the piers and through the hollow axis to the cube, whence it is directed to the eye-end by a system of prisms.[4]

The time of the star's transit over the middle wire is never exactly equal to the actual time of its meridian passage, as the plane in which the telescope turns never absolutely coincides with the meridian. Let the production of the west end of the axis meet the celestial sphere in a point of which the altitude above the horizon is b (the error of inclination), and of which the azimuth is $90°-a$ (the azimuth being counted from south through west), while the optical axis of the telescope makes the angle $90° + c$ with the west end of the axis of the instrument, then the correction to the observed time of transit will be $\{a \sin(\phi-\delta) + b \cos(\phi-\delta) + c\} / \cos\delta$, where ϕ is the latitude of the station and δ the declination of the star. This is called Tobias Mayer's formula, and is very convenient if only a few observations have to be reduced. Putting $b \sin\phi - a \cos\phi = n$, we get Hansen's formula, which gives the correction $= b \sec\phi + n (\tan\delta - \tan\phi) + c \sec\delta$, which is more convenient for a greater number of observations. The daily aberration is always deducted from c, as it is also multiplied by $\sec\delta$ (being $0{\cdot}31'' \cos\phi \sec\delta$). The above corrections are for upper culmination; below the pole $180° - \delta$ has to be substituted for δ. The constant c is determined by pointing the instrument on one of the collimators, measuring the distance of its wire-cross from the centre wire of the transit circle by a vertical wire movable by a micrometer screw, reversing the instrument and repeating the operation, or (without reversing) by pointing the two collimators on one another and measuring the distance of first one and then the other wire-cross from the centre wire. The inclination b is measured directly by a level which can be suspended on the pivots.[5] Having thus found b and c, the observation of two stars of known right ascension will furnish two equations from which the clock error and the azimuth can be found. For finding the azimuth it is most advantageous to use two stars differing as nearly 90° in declination as possible, such as a star near the pole and one near the equator, or better still (if the weather permits it) two successive meridian transits of a close circumpolar star (one above and one below the pole), as in this case errors in the assumed right ascension will not influence the result.

The interval of time between the culminations or meridian transits of two stars is their difference of right ascension, 24 hours corresponding to 360° or 1 hour to 15°. If once the *absolute right ascensions* of a number of *standard stars* are known, it is very simple by means of these to determine the R.A. of any number of stars. The absolute R.A. of a star is found by observing the interval of time between its culmination and that of the sun. If the inclination of the ecliptic (ϵ) is known, and the declination of the sun (δ) is observed at the time of transit, we have $\sin\alpha \tan\epsilon = \tan\delta$, which gives the R.A. of the sun, from which, together with the observed interval of time corrected for the rate of the clock, we get the R.A. of the star. Differentiation of the formula shows that observations near the equinoxes are most advantageous, and that errors in the assumed ϵ and the observed δ will have no influence if the $\Delta\alpha$ is observed at two epochs when the sun's R.A. is A and $180°-$A or as near thereto as possible. A great number of observations of this kind will furnish materials for a standard catalogue; but the right ascensions of many important catalogues have been found by making use of the R.A.'s of a previous catalogue to determine the clock error and thus to improve the individual adopted R.A.'s of the former catalogue.

In order to determine absolute declinations or polar distances, it is first necessary to determine the co-latitude (or distance of the pole from the zenith) by observing the upper and lower culmination of a number of circumpolar stars. The difference between the circle reading after observing a star and the reading corresponding to the zenith is the zenith distance of the star, and this plus the co-latitude is the north polar distance or $90° - \delta$. In order to

[1] Reichenbach supplied his tubes with counterpoising levers like those on the Dorpat refractor (see TELESCOPE).

[2] *Comptes rendus*, lxxxvii. 24.

[3] The transits are either observed by "eye and ear," counting the second beats of the clock and comparing the distance of the star from the wire at the last beat before the transit over the wire with the distance at the first beat after the transit, in this way estimating the time of transit to $0{\cdot}1^s$; or the observer employs a "chronograph," and by pressing an electric key causes a mark to be made on a paper stretched over a uniformly revolving drum, on which the clock beats are at the same time also marked electrically.

[4] The idea of illuminating through the axis is due to H. Ussher, professor of astronomy in Dublin (d. 1790).

[5] To avoid the use of a very large level, the pivots of the new transit circle at Kiel are supplied with small "riders" carrying a wire-cross; these can in turn be observed through a horizontal telescope with a hanging mirror in front of its object-glass, whereby the difference in height of the two pivots above a horizontal line may be measured.

determine the zenith point of the circle, the telescope is directed vertically downwards and a basin of mercury is placed under it, forming an absolutely horizontal mirror. Looking through the telescope the observer sees the horizontal wire and a reflected image of the same, and if the telescope is moved so as to make these coincide, its optical axis will be perpendicular to the plane of the horizon, and the circle reading will be 180° + zenith point. In observations of stars refraction has to be taken into account as well as the errors of graduation and flexure, and, if the bisection of the star on the horizontal wire was not made in the centre of the field, allowance must be made for curvature (or the deviation of the star's path from a great circle) and for the inclination of the horizontal wire to the horizon. The amount of this inclination is found by taking repeated observations of the zenith distance of a star during the one transit, the pole star being the most suitable owing to its slow motion.

Attempts have been made in various places to record the transits of a star photographically; with most success at the Georgetown College Observatory, Washington (since 1889). A sensitive plate is placed in the focus of a transit instrument and a number of short exposures made, their length and the time they are made being registered automatically by a clock. The exposing shutter is a thin strip of steel, fixed to the armature of an electromagnet. The plate thus gives a series of dots or short lines, and the vertical wires are photographed on the plate by throwing light through the object-glass for one or two seconds. This seems to give better results than the method adopted at the Paris observatory, where the plate is moved by clock-work and the exposure is comparatively long, while the image of a fixed slit is photographed at different recorded instants.

Literature.—The methods of investigating the errors of a transit circle and correcting the results of observations for them are given in Brünnow's and Chauvenet's manuals of spherical astronomy. For detailed descriptions of modern transit circles, see particularly the *Washington Observations* for 1865, the *Publications* of the Washburn Observatory (vol. ii.) and *Astronomische Beobachtungen zu Kiel* (1905). The Greenwich circle is described in an appendix to the *Greenwich Observations* for 1852. Accounts of photographic transit instruments will be found in *The Photochronograph* (Washington, 1891), *Annales de l'observatoire de Tokyo*, tome iii. and *Comptes rendus* (July 16, 1906). (J. L. E. D.)

TRANSKEI, one of the divisions of the Cape province, South Africa, east of the Kei River, being part of the country known variously as Kaffraria ((*q.v.*), " the Native Territories " (of the Cape) and the Transkeian Territories. The majority of the inhabitants are Fingo (*q.v.*).

TRANSLATION (Lat. *trans*, across, and *latus*, the participle of *ferre*, to carry), literally a carrying over or transference from one to another, and so from one medium to another. Among the more literal usages is the translation of Enoch in the Bible (Heb. xi. 5), or the ecclesiastical removal of a bishop to another see. But the commonest sense of the word is in connexion with the rendering of one language into another.

The characteristics of a good translation in the literary sense, and the history of the influence, through translations, of one literature on another, are worth more detailed notice. Dryden has prescribed the course to be followed in the execution of the ideal translation: " A translator that would write with any force or spirit of an original must never dwell on the words of his author. He ought to possess himself entirely, and perfectly comprehend the genius and sense of his author, the nature of the subject, and the terms of the art or subject treated of; and then he will express himself as justly, and with as much life, as if he wrote an original; whereas, he who copies word for word loses all the spirit in the tedious transfusion." Comparatively few translators have satisfied this canon. A writer capable of attaining the standard set up by Dryden is naturally more disposed to use his powers to express his own views than those of his foreign predecessors. No doubt at all times, and in all countries, translations have usually been produced for utilitarian purposes, and not from artistic motives. In the first instance we may assume that translations were undertaken in a spirit of educational propaganda as a means of communicating new ideas and new facts to a somewhat uninstructed and uncritical public, indifferent as to matters of form. But, though the translator's primary motive is didactic, he is insensibly led to reproduce the manner as well as the matter of his original as closely as possible. Montaigne warns aspirants of the difficulty in dealing with authors remarkable for the finish of their execution. " Il faict bon," he writes in the *Apologie de Raimond Sebonde*, " traduire les aucteurs comme celuy-là ou il n'y a guères que la matière à représenter; mais ceux qui ont donné beaucoup à la grace et à l'élégance de langage ils sont dangereux à entreprendre nommément pour les rapporter à un idiome plus foible." As it happens, however the task of translating foreign masterpieces has frequently been undertaken by writers of undisputed literary accomplishment whose renderings have had a permanent effect on the literature of their native country.

It was certainly the case when Rome, having conquered Greece, was captured by her captive. There is much point and little exaggeration in the statement that " when the Greek nation became a province of Rome, the Latin literature became a province of the Greek "; and this peaceful victory was initiated by a series of translations made by writers of exceptional ability and, in some cases, of real genius. The first translator whose name is recorded in the history of European literature is L. Livius Andronicus, a manumitted Greek slave who about 240 B.C., rendered the *Odyssey* into Saturnian verse. This translation, of which some fragments are preserved, was long in use as a school text, for Horace studied it under the formidable Orbilius; but Andronicus appears to have recognized his mistake in using the native Latin measure as a vehicle of literary expression, and is said to have rendered Greek tragedies and comedies into metres corresponding to those of his Greek originals. The decision was momentous, for it influenced the whole metrical development of Latin poetry. The example set by Andronicus was followed by Naevius and Ennius, both of whom laid the foundations of the Latin theatre by translating Greek plays—especially those of Euripides—and naturalized in Rome the hexameter, which, as practised later by Lucretius and Virgil, was destined to become " the stateliest measure ever moulded by the lips of man." The tradition of translating more or less freely was continued by Pacuvius, the nephew of Ennius, as well as by Plautus and Terence, whose comedies are skilful renderings or adaptations from the New Attic Comedy of Philemon, Diphilus and Menander. A persistent translator from the Greek was Cicero, who interpolates in his prose writings versified renderings of passages from Homer, Aeschylus, Sophocles and Euripides which prove the injustice of the popular verdict on his merits as a poet. Cicero not only translated the oration of Demosthenes *On the Crown*, but also made Latin versions of Plato's *Timaeus* (part of which survives), of Xenophon's *Oeconomicus*, and of the *Phaenomena*, an astronomical poem by Aratus of Soli, an Alexandrian imitator of Hesiod. This last performance was a tribute to the prevailing fashion of the moment, for the Alexandrian poets had supplanted the early Greek school in favour among the literary circles of Rome. To the foregoing list may be added the great name of Catullus, whose *Coma Berenices* is translated from Callimachus, and Cornelius Gallus is mentioned as a translator of Euphorion. Complete translations became less and less necessary as a knowledge of Greek spread among the educated class. But the practice of translating fragments of Greek verse continued throughout the classic period of Latin literature, and the translations of Greek originals incorporated by Virgil were duly pointed out by Octavius Avitus.

The knowledge of Greek declined with the empire, and translations were accordingly produced for the benefit of students who were curious concerning the philosophic doctrines of the Athenians and the Neoplatonists. Porphyry's introduction to Aristotle's *Categories* was translated by Victorinus about the reign of Julian the Apostate; at the end of the 5th century this introduction was once more translated by Boetius, whose translations of Aristotle's *Categories* and other logical treatises began the movement which ended in establishing the Greek philosopher as the most profound and authoritative exponent of intellectual problems during the middle ages. Plato was less fortunate, for he was known to students chiefly by the Latin version of the *Timaeus* made by Chalcidius (it is said) for Hosius, the bishop of Cordova. Cassiodorus, the contemporary of Boetius, went farther afield when he ordered a Latin translation of Josephus to be prepared; but the interest in Aristotle extended to the

East, and in the 6th century he was translated into Syriac by Sergius of Resaina. The Syrians acted as interpreters of Greek learning to the Arabs, and during the 8th and 9th centuries—chiefly through the staff of translators organized at Bagdad by Honein ibn Ishak—the works of Plato and Aristotle, as well as those of Hippocrates and Galen, were translated into Arabic. These translations are of capital importance in the history of European thought. Many of them were introduced into Spain by the Arabs, and were rendered—in some cases through the intermediary of a Castilian-speaking Jew—into Latin at the college of translators founded in 1130 (or shortly afterwards) at Toledo by Raymund, archbishop of that city. Circulating widely throughout western Europe, these Latin translations supplied the learned with a third- or fourth-hand knowledge of Greek philosophy. When Albertus Magnus, St Thomas Aquinas, or any other early light of the schools refers to Aristotle, it must be borne in mind that he often had no more exact acquaintance with the text which he expounds or confutes than could be gathered from an indirect Latin version of an Arabic rendering of a Syriac translation of a Greek original. This accounts for many misunderstandings and errors which would otherwise be incomprehensible. Among the earliest European translators who made their way to Toledo were Adelard of Bath, who rendered an Arabic version of Euclid into Latin; the Englishman known as Robert de Retines, afterwards archdeacon of Pamplona, the first translator of the Koran, which he did into Latin in 1141–1143 by order of Peter the Venerable; and Gerard of Cremona, who, towards the end of the 12th century, was responsible for over seventy translations from the Arabic, including Ptolemy's *Almagest* and many of Aristotle's treatises, as well as works by Galen, Hippocrates and Avicenna. Early in the 13th century Michael Scot, who had begun his Arabic studies at Palermo, visited Toledo and (perhaps with the help of the Jew Andreas, if we are to believe the statement of Hermann the German, repeated by Roger Bacon) translated into Latin various works of Aristotle, Avicenna, and—more especially—Averroes. These Latin translations by Michael Scot introduced Averroes to the notice of Western scholars, and the fact that they were used at the universities of Paris and Bologna gave the first impetus to the vogue of Averroistic doctrine which lasted from the time of St Thomas Aquinas to the rise of Martin Luther. At Toledo, between 1240 and 1256, Hermann the German translated into Latin the commentaries of Averroes on Aristotle's *Ethics*, together with abridgments of the *Poetic* and the *Rhetoric* made respectively by Averroes and Alfarabi. But, at the very period of Hermann the German's residence at Toledo, a more satisfactory method of translation was begun. Within half a century of the conquest of Constantinople in 1204 a visit to Spain was no longer indispensable for a would-be translator of Greek philosophical treatises. The original texts slowly became more available, and a Latin translation of Aristotle's *Ethics* seems to have been made from the Greek by order of Robert Grosseteste, bishop of Lincoln, between 1240–1244. Towards the end of the century the indefatigable William of Moerbeke (near Ghent)—mentioned as " William the Fleming " by Roger Bacon—produced, amongst numerous other Latin renderings from the Greek, versions of Aristotle's *Rhetoric* and *Politics* which have commended themselves to more exact scholars of the modern German type. The Latin renderings from the Arabic were current till a much later date; but it was henceforth accepted, at least in principle, that translations of the Greek classics should be made direct from the original text.

Meanwhile the work of translating foreign productions into the local vernacular had been begun in the north and west of Europe. Towards the end of the 9th century an illustrious English translator appeared in the person of King Alfred, who rendered St Gregory the Great's *Cura pastoralis* into West Saxon " sometimes word for word, sometimes sense for sense." Alfred is also regarded, though with less certainty, as the translator of Bede's *Historia ecclesiastica* and the *Historia adversus paganos* of Orosius. The version of St Gregory's treatise is the most literal of the three; omissions are frequent in the renderings of Bede and Orosius, and in all the diction is disfigured by latinisms. A larger conception of a translator's function is noticeable in Alfred's version of Boetius's *De consolatione philosophiae*, a famous Neoplatonic treatise which was the delight of the middle ages, and was translated later into German by Notker Labeo, into French by Jean de Meung, and twice again into English by Chaucer and by Queen Elizabeth respectively. In translating Boetius, Alfred deals more freely with his author, interpolates passages not to be found in the extant texts of the original, and yet succeeds in giving an adequate interpretation which is also an excellent specimen of English prose. If the alliterative verses found in one manuscript of Alfred's translation are accepted as his work, it is clear that he had no poetic faculty; but he has the credit of opening up a new path, of bringing England into contact with European thought, and of stimulating such writers as Werferth, bishop of Worcester—the translator of St Gregory's *Dialogues*—to proceed on the same line. Some forty years earlier John Scotus (Erigena) had won celebrity as a translator by his Latin renderings of works ascribed to the mysterious 5th century Neoplatonist who passes under the name of Dionysius the Areopagite. Towards the close of Alfred's reign some countrymen of Erigena bettered his example by producing Irish versions of Hippocrates and Galen at St Gallen. St Gallen became a centre of translation, and there, at the beginning of the 11th century, Notker Labeo presided over a committee of interpreters who issued German renderings of certain treatises by Aristotle, Terence's *Andria* and Virgil's *Eclogues*. Far greater literary importance attaches to *Syntipas*, the title given by Michael Andreopulos to a collection of ancient Oriental tales which he translated from an intermediate Syriac version into Greek at the request of the Armenian duke of Melitene about the end of the 11th century. These stories were retranslated into French verse and (by Jean de Haute-Seille) into Latin during the course of the 12th century under the respective titles of the *Sept sages de Rome* and *Dolopathos*; they were utilized in the *Cento novelle antiche*, in the *Libro dei sette savj*, and in the *Decamerone*, and were finally absorbed by every literature in Europe. Immense popularity was won by the *Liber gestorum Barlaam et Josaphat*, a Latin translation made in the 11th or 12th century from the Greek, and recast in many European languages during the 13th century. The book is in fact a legendary life of Buddha adapted to the purposes of Christianity by a monk; but it was accepted as an historical record, the undiscerning credulity of the faithful informally canonized Barlaam and Josaphat, and ultimately compelled the Latin Church to include these two fictitious beings as saints in the *Martyrologium romanum*. This is perhaps the most curious result attained by any translation. The interest in Eastern apologues and moralizing stories, which was early shown in Marie de France's translation of Aesopic fables, was further demonstrated by the Castilian translations of *Kalilah and Dimnah* and *Sindibad* made about the middle of the 13th century, by (or at the command of) Alphonso the Learned and his brother the Infante Fadrique respectively.

The enthusiasm for these Oriental stories was communicated to the rest of Europe by John of Capua's *Directorium humanae vitae* (1270), a Latin translation of *Kalilah and Dimnah*; but, in the meanwhile, as the younger European literatures grew in power and variety, the field of translation necessarily widened to such an extent that detailed description becomes impossible. Geoffrey of Monmouth's *Historia regum Britanniae*, which purports to be a free version of an unnamed Breton book, is the source of the Arthurian legends which reappeared transformed in elaborate French versions, and were transmitted to the rest of Europe during the 12th and 13th centuries. During this period of French literary supremacy instances of bilingual faculty are not wanting in the form of translations: shortly after the middle of the 13th century Brunetto Latini translated passages of Cicero into Italian, and selections from Sallust into French. A hundred years later there are unmistakable indications that the middle ages are departing, that the French suzerainty over literature is at an end, and that the advent of the New Humanism is an accomplished fact. The early Renaissance had already dawned in Italy: a renewed interest in the Latin classics (Greek was not yet generally cultivated by scholars) proved that there was a revival of learning in France. Livy was done into French by Bersuire, Seneca by Bauchant, Boccaccio by Laurent de Premier Fait, and a celebrated translator appeared in the person of Nicolas Oresme, who, however, rendered Aristotle from a Latin version. In England Chaucer executed translations of Boetius and part of the *Roman de la rose*, and succeeded equally in interpreting the philosophic treatise and the allegorical poem. A still further advance is discernible in the book of travels ascribed to Sir John Mandeville: this work, which seems to have been originally written in French, is rendered into English with an exceptional felicity which has won for the translator the loose-fitting but not altogether inappropriate title of " the father of English prose." The English version of Mandeville is assigned to the beginning of the 15th century. About 1470 Sir Thomas Malory produced from French originals his *Morte d'Arthur*, a pastiche of different texts translated with a consummate art which amounts to originality. Malory's inspired version, together with the numerous renderings from the French issued (and often made personally) by Caxton, stimulated the public taste for romantic narrative, raised the standard of execution, and invested the translator with a new air of dignity and importance.

Yet the 15th century has a fair claim to be regarded as the golden age of translation. The Gothic version of the Bible, made by Ulfilas during the 4th century almost simultaneously with St Jerome's Vulgate, is invaluable as the sole literary monument of a vanished language; the 14th century English version by Wycliffe and the 15th century English versions which bear the names of Tyndale and Coverdale are interesting in themselves, and are also interesting as having contributed to the actual Authorized Version of 1611. But they are incomparably less important than Luther's German translation of the Bible (1522–1534) which, apart from its significance as indicating the complete victory of the liberal middle class and the irremediable downfall of the feudal and ecclesiastical autocracy, supplanted minor dialects and fixed the norm of literary expression in German-speaking countries. Luther, it has been truly said, endowed Germany with a uniform literary language, a possession which she had lost for nearly three hundred years. The effect of profane literature was speedily visible in Fischart's translations of Rabelais's *Pantagruéline* (1572) and the first book of *Gargantua* (1575). But before this date France had produced a prince of translators in Jacques Amyot, bishop of Auxerre. In 1548 Nicolas de Herberay had published a French translation of *Amadis de Gaule* which enchanted the polite world at the court of Henry II., had its day, and is forgotten. But Amyot's translation of Plutarch (1559) remains an acknowledged masterpiece, surviving all changes of taste and all variations of the canon of translation. Montaigne writes: " Je donne la palme avecque raison, ce me semble, â Jacques Amyot, sur tous nos escripvains François." If " escripvain " be understood to mean " translator," this judgment is beyond appeal.

Lord Berners will not bear comparison with Amyot in achievement or influence; but. though less completely equipped and less uniformly happy in his choice of texts (for Amyot translated the *Aethiopian History* and *Daphnis and Chloe* as well as Plutarch), Lord Berners holds a distinguished place in the ranks of English translators. His renderings of Fernández de San Pedro's *Cârcel de amor* and of Guevara's *Libro aureo* are now read solely by specialists engaged in tracing English euphuism to its remoter sources, and some of his other translations—the *Boke of Duke Huon of Burdeux* and *Arthur of Little Britain*—are too poor in substance to be interesting nowadays. But Lord Berners is justly remembered by his notable translation of Froissart (1523–1525). Froissart offers fewer opportunities than Guevara for the display of that " fecundious art of rhetoric " in which the English translator thought himself deficient, and, with this temptation removed, Lord Berners is seen at his best. In his version of Froissart, apart from endless confusion of proper names, he makes few mistakes of any real importance, and, if he scarcely equals his original in *brio*, he is almost invariably adequate in reproducing the French blend of simplicity with stateliness. Such translations as Phaer's *Virgil* (1557) and Golding's *Ovid* (1561) have not the historical importance of William Painter's *Palace of Pleasure*, a miscellaneous collection of stories rendered from the Italian, nor of Jasper Heywood's version of Seneca (1581) whose plays had exercised immense influence upon the methods of Garnier and Montchrétien in France. Though Kyd translated Garnier's *Cornélie*, the Senecan system was destined to defeat in England, and Heywood's translation did not even postpone the catastrophe. On the other hand Marlowe found the subject of his *Tamburlaine* in Painter's collection, and thus began the systematic exploitation of the *Palace of Pleasure* which was continued by his successors on the stage. A translator of the rarest excellence was forthcoming in Sir Thomas North, who rendered Guevara (1557) from the French (revising his second edition from the Spanish), and *The Morall Philosophie of Doni*—" a worke first compiled in the Indian tongue "—from the Italian (1570). But, good as they are, both these versions are overshadowed by the famous translation of Plutarch which North published in 1579. He may have referred occasionally to the Greek, or perhaps to some intermediate Latin rendering; but the basis of his work is Amyot, and his English is not inferior to the French in sonority and cadence of phrase. This retranslation of a translation is a masterpiece of which fragments are incorporated with scarcely any change in *Coriolanus*, *Julius Caesar* and *Antony and Cleopatra*; and touches from North have been noted also in the *Midsummer Night's Dream* and in *Timon of Athens*. Amyot greatly influenced the development of French prose, and his translation was the source of Racine's *Mithridate*; but, if we reflect that Shakespeare not only took some of his subjects from the English Plutarch and found nothing to amend in the diction of many passages, North's triumph may be reckoned as even more signal than Amyot's. Very little below North's translation of Plutarch comes John Florio's translation of Montaigne (1603), a fantastically ingenious performance which contributed a celebrated passage to *The Tempest* and introduced the practice of the essay into England. It is impossible to cope with the activity of English translators during the last half of the 16th century and the first half of the 17th. To this period belongs Chapman's impressive and resounding translation (1598–1616) of Homer, which was to enrapture Keats two hundred years later. Adlington's version of Apuleius, Underdown's renderings of Heliodorus and Ovid, the translations of Livy, Pliny, Suetonius and Xenophon issued in quick succession by Philemon Holland are vivid and often extravagantly picturesque in their conveyance of classic authors into Elizabethan prose. With them must be named the translator of Tacitus (1591), Sir Henry Savile, who served later on the committee which prepared the Authorized Version of the Bible, and must therefore be counted amongst those who have exercised a permanent influence on English prose style. Thomas Shelton produced the earliest translation (1612) of *Don Quixote*, a version which, in spite of its inaccuracies and freakishness, preserves much of the tone and atmosphere of the original. Mabbe's translation (1622) of *Guzmán de Alfarache* was lauded by Ben Jonson, and widely read during the 17th century, and his version of the *Celestina* deserved a success which it failed to obtain. It compares most favourably with a version of Tasso (1600) by Edward Fairfax, who has been persistently overpraised. But the Puritanical instinct of the English people, powerful even when not in the ascendant, was an insuperable obstacle to the acclimatization of Spanish literature in England. The *Leviathan* has obscured Hobbes's fame as a translator, but he is known to scholars by his sound but crabbed rendering of Thucydides (1629), and by a wholly unnecessary version of Homer which he published at the very end of his career (1674). Sir Roger L'Estrange is responsible for translations of Seneca, Cicero and Josephus, which are usually lively enough to be readable and unfaithful enough to be misleading; the most popular of his renderings is a translation of Quevedo's *Sueños* (made through the French) which owes most of its vogue during the Restoration rather to its reckless indecency than to its intrinsic merit. Dryden's free translations of Juvenal (1693) and Virgil (1697) treat the original authors with a cavalier freedom, but at least they preserve the meaning, if not the conciseness and point, of the Latin.

Among the multitudinous English translations of the 18th century it is only necessary to mention Pope's versions of the *Iliad* (1715–1720) and the *Odyssey* (1725–1726), and Cowper's rendering of Homer, issued in 1791. These neat translations necessarily fail to convey any impression of Homer's epical grandeur, and they set a mischievous fashion of artificial "elegance" which has been too often adopted by their successors; but both Pope and Cowper conform faithfully to the mistaken canon of their age, and both have fugitive moments of felicity. A posthumous translation of *Don Quixote* bearing the name of Charles Jarvis appeared in 1742, has been reprinted times innumerable ever since, and has helped to make Cervantes's masterpiece known to generations of English-speaking people. Defective in point of exact scholarship, it has the merit of agreeable perspicuity, and there seems no reason to believe the remark, ascribed by Warburton to Pope, that Jarvis "translated *Don Quixote* without knowing Spanish": the available evidence is strongly against this malicious theory. The most remarkable translations of the 18th century, however, appeared in Germany: these are the versions of the *Odyssey* (1781) and *Iliad* (1793) by Voss, and A. W. von Schlegel's rendering of Shakespeare (1797–1810), which gave a powerful impulse to the romantic movement on the Continent.

Byron's version of a Spanish ballad and Shelley's renderings of Calderón are interesting exhibitions of original genius voluntarily accepting a subordinate rôle. More importance attaches to Carlyle's translation of *Wilhelm Meister* (1824), a faithful rendering free from the intolerable mannerisms and tricks which the translator developed subsequently in his original writings. William Taylor had long before translated Bürger's *Lenore*, Lessing's *Nathan* and Goethe's *Iphigenia*; but such interest as the English nation has been induced to take in German literature dates from the appearance of Carlyle's translation. If he did nothing more, he compelled recognition of the fact that Germany had at last produced an original genius of the highest class. Calderón found accomplished translators in Denis Florence MacCarthy (1848–1873) and in Edward FitzGerald (1853), who also attempted to render Sophocles into English; but these are on a much lower plane than the translation of the *Rubaiyát* (1859) of Omar Khayyam, in which, by a miracle of intrepid dexterity, a half-forgotten Persian poet is transfigured into a pessimistic English genius of the 19th century. Versions of Dante by Longfellow (whose translations of poems by minor authors are often admirable), of Latin or Greek classics by Conington, Munro, Jowett and Jebb, maintain the best traditions of the best translators. William Morris was less happy in his poetical versions of *Virgil* (1875) and the *Odyssey* (1887) than in his prose translations of *The Story of Grettir the Strong* (1869) and *The Volsunga Saga* (1870)—both made in collaboration with Magnússon—and in his rendering of *Beowulf* (1895). In his *Lays of France* (1872) Arthur O'Shaughnessy skirts the borders of translation without quite entering into the field; he elaborates, paraphrases and embroiders rather than translates the *lais* of Marie de France.

Most versions of modern foreign writers are mere hackwork carelessly executed by incompetent hands, and this is even more true of England than of France and Germany. But, with the development of literature in countries whose languages are unfamiliar, the function of the translator increases in importance, and in some few cases he has risen to his opportunity. Through translations the works of the great Russian novelists have become known to the rest of Europe, and through translations of Ibsen the dramatic methods of the modern stage have undergone a revolution. (J. F.-K.)

TRANSOM (probably a corruption of Lat. *transtrum*, a thwart, in a boat; equivalents are Fr. *traverse, croisillon*, Ger. *Losholz*), the architectural term given to the horizontal lintel or beam which is framed across a window, dividing it into stages or heights. In early Gothic ecclesiastical work transoms are only found in belfry unglazed windows or spire lights, where they were deemed necessary to strengthen the mullions in the absence of the iron stay bars, which in glazed windows served a similar purpose. In domestic work, on account of the opening casements, they are more frequently found. In the later Gothic, and more especially the Perpendicular period, the introduction of transoms became very general in windows of all kinds.

TRANSUBSTANTIATION, the term adopted by the Roman Catholic Church to express her teaching on the subject of the conversion of the Bread and Wine into the Body and Blood of Christ in the Eucharist. Its signification was authoritatively defined by the Council of Trent in the following words: "If any one shall say that, in the Holy Sacrament of the Eucharist there remains, together with the Body and Blood of Our Lord Jesus Christ, the substance of the Bread and Wine, and shall deny that wonderful and singular conversion of the whole substance of the Bread into (His) Body and of the Wine into (His) Blood, the species only of the Bread and Wine remaining—which conversion the Catholic Church most fittingly calls Transubstantiation—let him be anathema." [1] The word Transubstantiation is not found earlier than the 12th century. But in the Eucharistic controversies of the 9th, 10th and 11th centuries the views which the term embodies were clearly expressed; as, for example, by Radbertus Paschasius (d. 865), who wrote that "the substance of the Bread and Wine is efficaciously changed interiorly into the Flesh and Blood of Christ," and that after the consecration what is there is "nothing else but Christ the Bread of Heaven." [2] The words "substantially converted" appear in the formula which Berengarius was compelled to sign in 1079. Assuming that the *Expositio canonis missae* ascribed to St Pietro Damiani (d. 1072) is doubtful, we may take it that the first use of the word is in a passage of Hildebert de Savardin [3] (d. 1133), who brings it into an exhortation quite informally, as if it were in common use.[4] It is met with in a Decretal of Innocent III.[5] The fourth Council of Lateran fully adopted it (1215). It is clear from the treatise of Radbertus Paschasius already quoted that the word "substance" was used for *reality* as distinguished from *outward appearance*, and that the word "species" meant *outward appearance* as opposed to *reality*. The terms, therefore, were not invented by St Thomas Aquinas, and are not mere scholastic subtlety. The definition of the Council of Trent was intended both to enforce the accepted Catholic position and to exclude the teaching of Luther, who, whilst not professing to be certain whether the "substance" of the Bread and Wine could or could not be said to remain, exclaimed against the intolerance of the Roman Catholic Church in defining the question.[6]

For a full and recent exposition of the Catholic teaching on Transubstantiation the reader may consult *De ecclesiae sacramentis*, auctore Ludovico Billot, S.J. (Rome, Propaganda Press, 1896). The Abbé Pierre Batifol, in his *Études d'histoire et de théologie positive*, 2me série (*Elaboration de la notion de conversion*, and *Conversion et transubstantiation*) treats it from the point of view of development (V. Lecoffre, Paris, 1905). (✠ J. C. H.)

TRANSVAAL, an inland province of the Union of South Africa between the Vaal and Limpopo rivers. It lies, roughly, between $22\frac{1}{2}°$ and $27\frac{1}{2}°$ S. and 25° and 32° E., and is bounded S. by the Orange Free State and Natal, W. by the Cape province and the Bechuanaland Protectorate, N. by Rhodesia, E. by Portuguese East Africa and Swaziland. Save on the south-west the frontiers, for the main part, are well defined natural features. From the south-west to the north-east corners of the colony is 570 m.; east

[1] *Concil trident.* Sess. XIII. Can. 2.

[2] P. L. Migne. CXX. *De corpore et sanguine Domini*, cap. viii. 2, cf. xv. 2.

[3] Sometimes called of Tours, or of Le Mans.

[4] See Batifol, *Études d'histoire et de théologie positive*, 2me série.

[5] Lib. III. *Decretalium*, tit. 41, n. 6.

[6] *De captivitate babylonica ecclesiae.* De coenâ Domini. But Luther elsewhere professed Consubstantiation; that is, in modern Lutheran phraseology, the "presence of our Lord's Body" in, with and under the bread.

to west its greatest extent is 397 m. The total area is 111,196 sq. m., a little less than the area of Great Britain and Ireland. The boundaries of the Transvaal have varied from time to time. The most important alteration was made in January 1903 when the districts of Utrecht and Vryheid, which then formed the south-eastern part of the country were annexed to Natal. The area thus lost to the Transvaal was 6970 sq. m. (For map see South Africa.)

Physical Features.—About five-sixths of the country lies west of the Drakensberg (*q.v.*), the mountain range which forms the inner rim of the great tableland of South Africa. For a few miles on the Natal-Transvaal frontier the Drakensberg run east and west and here is the pass of Laing's Nek. Thence the mountains sweep round to the north, with their precipitous outer slopes facing east. For some 250 m. within the province the mountains form a more or less continuous range, the highest point being the Mauchberg (8725 ft.) in 24° 20′ 10″ S. 30° 35′ E., while there are several heights of 7000 or more feet. Eastward from the foot of the Drakensberg stretches a broad belt of low land beyond which rise the Lebombo hills running north and south along the parallel of 32° E. and approaching within 35 m. of the sea at Delagoa Bay. The Lebombo hills are flat topped but with a well-defined break on their seaward side. This eastern edge forms the frontier between Transvaal and Portuguese territory.

The country west of the Drakensberg, though part of the main South African tableland, is not uniform in character, consisting of (1) elevated downs, (2) their slopes, (3) the flat "bottom" land. The downs or plateaus occupy all the southern part of the country, sloping gradually westward from the Drakensberg. That part of the plateau east of Johannesburg is from 5000 to 6400 ft. high; the western and somewhat larger half is generally below 5000 ft. and sinks to about 4000 ft. on the Bechuanaland border. This plateau land is called the high veld,[1] and covers about 34,000 sq. m. The northern edge of the plateau follows an irregular line from somewhat north of Mafeking on the west to the Mauchberg on the east. This edge is marked by ranges of hills such as the Witwatersrand, Witwatersberg and Magaliesberg; the Witwatersrand, which extends eastward to Johannesburg, forming the watershed between the rivers flowing to the Atlantic and Indian Ocean. Farther north, beyond the intervening slopes and low bush, are two elevated regions covering together over 4000 sq. m. They are the Waterberg, and, more to the east, separated from the Waterberg by the valley of the Magalakwane tributary of the Limpopo, the Zoutpansberg. The Zoutpansberg has steep slopes and is regarded as the northern termination of the Drakensberg. An eastern offshoot of the Zoutpansberg is known as the Murchison Range. The low land between the high veld and the Waterberg and Zoutpansberg is traversed by the Olifants River, an east flowing tributary of the Limpopo.

The true high veld, extending east to west 120 m. and north to south 100 m., consists of rolling grass covered downs, absolutely treeless, save where, as at Johannesburg, plantations have been made by man, the crest of the rolls being known as *builts* and the hollows as *laagtes* or *vleys*. The surface is occasionally broken by kopjes—either table-shaped or pointed—rising sometimes 100 ft. above the general level. Small springs of fresh water are frequent and there are several shallow lakes or pans—flat bottomed depressions with no outlet. The largest of these pans, Lake Chrissie, some 5 m. long by 1 m. broad, is in the south-eastern part of the high veld. The water in the pans is usually brackish. The middle veld is marked by long low stony ridges, known as rands, and these rands and the kopjes are often covered with scrub, while mimosa trees are found in the river valleys.

The banken veld, formed by the denudation of the plateau, is much broken up and is rich in romantic scenery. It covers about 27,000 sq. m., and has an average breadth of 40 m. In places, as between Mafeking and Johannesburg, the descent is in terrace-like steps, each step marked by a line of hills; in other places there is a gradual slope and elsewhere the descent is abrupt, with outlying hills and deep well-wooded valleys. The rocks at the base of the slopes are granite, the upper escarpments are of sedimentary rocks. Thence issue many streams which in their way to the ocean have forced their way through the ranges of hills which mark the steps in the plateau, forming the narrow passes or *poorts* characteristic of South African scenery.

As in the middle veld, rands and kopjes occur in the low or bush veld, but the general characteristic of this part of the country, which covers over 50,000 sq. m., is its uniformity. The low veld east of the Drakensberg begins at about 3000 ft. above the sea and slopes to 1000 ft. or less until it meets the ridge of the Lebombo hills. The lowest point is at Komati Poort, a gorge through the Lebombo hills only 476 ft. above the sea. West and north of the Drakensberg the general level of the low veld is not much below that of the lowest altitudes of the middle veld, though the climatic conditions greatly differ. North of the Zoutpansberg the ground falls rapidly, however, to the Limpopo flats which are little over 1200 ft. above the sea. Near the north-west foot of the Zoutpansberg is the large saltpan from which the mountains get their name. The low veld is everywhere covered with scrub, and water is scarce, the rivers being often dry in the winter season.

River Systems.—There are four separate river basins in the Transvaal. Of these the Komati (*q.v.*) and its affluents, and the Pongola and its affluents rise in the high veld and flowing eastward to the Indian Ocean drain but a comparatively small area of the province, of which the Pongola forms for some distance the south-eastern frontier. The rest of the country is divided between the drainage areas of the Vaal and Limpopo. The Vaal (*q.v.*) rises in the nigh veld in the Ermelo district not far from the source of the Komati and that of the Usuto tributary of the Pongola. The Vaal drains the greater part of the plateau, flowing westward towards the Atlantic. The waters of the northern escarpments of the plateau and of all the region farther north are carried to the Indian Ocean by the Limpopo (*q.v.*) and its tributaries the Olifants, Great Marico, Great Letaba, &c. Both the Vaal and the Limpopo in their main course have high steep banks. They carry an immense volume of water during the summer rains, but are very small streams in the winter, when several of their tributaries are completely dry.[2] None of the rivers is navigable within the limits of the province. The absence of alluvial deposits of any size is another characteristic of the Transvaal rivers. For a considerable distance the Vaal forms the frontier between the province and the Orange Free State and in similar manner the Limpopo separates the Transvaal from Bechuanaland and Rhodesia. Since the first advent of white colonists many springs and pans and small streams have dried up, this desiccation being attributed, not so much to decreased rainfall, as to the burning off of the grass every winter, so that the water, instead of soaking in, runs off the hard, baked ground into the larger rivers. (F. R. C.)

Geology.

A broad ring of crystalline rocks (Swaziland schists) encircles the Transvaal except on the south, where the Karroo formation extends over the Vaal River. Within this nearly complete circle of crystalline rocks several geological formations have been determined, of which the age cannot be more definitely fixed than that they are vastly older than the Karroo formation and newer than the Swaziland schists.

The following subdivisions have been recognized by Molengraaff: Karroo System, Transvaal System, Vaal River System, South African Primary System. Each of these systems is separated from the other by a strong unconformity.

South African Primary System.—The South African Primary System includes a complex of rocks as yet little understood. According to Molengraaff it includes the two following series:—

Witwatersrand Series.	An upper group including the auriferous conglomerates of the Rand: a lower group (Hospital Hill series) of quartzites, shales and conglomerates.
Barberton and Swaziland Series.	Crystalline schists, quartzites, conglomerates, intrusive granites.

Barberton Series.—Molengraaff considers the Barberton series to be the metamorphosed equivalent of the Hospital Hill series, while Hatch regards it to be older and to form a portion of his Archaean series (Swaziland schists) to which position it is here assigned. The chief outcrops are in the south-western Transvaal, around Zoutpansberg and in Swaziland. They show a great variety of type made up of slates, quartzites, occasional conglomerates, schists with large masses of intrusive granites and gneiss.

Witwatersrand Series.—It is now generally acknowledged that this important series consists of two main groups. Their chief occurrences are in the districts of Witwatersrand, Heidelberg, Klerksdorp and Venterskroon. The lower group (Hospital Hill slates) consists of quartzites and shales, resting on the eroded surface of the older granites and schists, and estimated to be from 10,000 to 12,000 ft. thick. There are occasional bands of conglomerates, sometimes auriferous. In the absence of fossils their age cannot be determined. The upper group consists of conglomerates, grits and quartzites with a few bands of shales. It has obtained notoriety from the conglomerates along certain bands containing gold, when they constitute the famous "banket." The thickness varies from 2300 to over 11,000 ft. The conglomerate beds occur in belts forming in descending order the Elsburg series, Kimberley series, Bird Reef series, Livingstone Reef series, Main Reef series. The richest in gold are to be found among the Main Reef series, which yields by far the greater part of the total output of gold from the Transvaal. The individual beds, seldom more than a few feet in thickness and sometimes only a few inches, are interstratified with an immense thickness of quartzites. The conglomerates consist almost entirely of pebbles of quartz set in a hard

[1] By the Boers the western and less elevated part of the plateau is known as the middle veld.

[2] At the Standerton gauge on the Vaal in 1905–1906, a year of extreme drought, the total flow was 8,017,000,000 cub. ft., of which 7,102,000,000 was storm water.

matrix consolidated by the deposition of secondary silica. The conglomerate bands and quartzites contain large quantities of iron pyrites deposited subsequent to their formation, that in the conglomerates containing the gold. Sericite in the form of scales and films characterizes those portions which have been faulted, squeezed or sheared. Sheets of diabase, apparently volcanic flows, and numerous dykes interfere with the regularity of the stratification. The theory of the subsequent infiltration of the gold is that generally accepted. No fossils have been discovered, and except that they represent some portion or portions of rocks of the Pre-Cape formation the age of the upper Witwatersrand beds, as well as that of the lower division, remains an open question. They may safely be considered to be among the oldest auriferous sediments of the world.

Vaal River System.—This consists largely of rocks of igneous origin, of which the amygdaloidal diabase of Klipriversberg forms the type. The other rocks include igneous breccias, shales, coarse conglomerates and grits. Near Reitzburg the coarse conglomerates reach a thickness of 400 ft. and about 500 ft. at Kroomdraai. This system rests unconformably on the Witwatersrand series and is unconformably overlain by the Transvaal system. It must, however, be acknowledged that these relationships are very imperfectly understood. Compared with other formations they occupy restricted areas, being only met with south of Johannesburg, around Wolmaransstad, Lichtenburg and east of Marico.

Transvaal System.—This is a very definite sequence of rocks covering immense areas in the centre of the country. The following groups are recognized: Waterberg Series, Pretoria Series, Dolomite Series, Black Reef Series.

The Black Reef Series is composed of quartzites, sandstone, slates and conglomerate. It varies in thickness from 100 ft. in the southern Transvaal to 1000 ft. at Lydenburg. Thin bands of conglomerate, sometimes auriferous, occur near the base.

The Dolomite Series, known to the Dutch as "Olifants Klip," consists of a bluish-grey magnesian limestone with bands of chert. The thickness varies from 2600 ft. in the Witwatersrand area to 5000 ft. around Pretoria; and is about 2600 ft. about Lydenburg. It is worn by solution into caves and swallow-holes (*Wondergarten*). Gold, lead, copper and iron ores occur as veins. So far it has proved to be unfossiliferous. Dykes and intrusive rocks are common.

The Pretoria Series, formerly known as the Gatsrand series, consists of repeated alternations of flagstones and quartzites, shales and sheets of diabase. These follow conformably on the Dolomite series. In the Marico district the shales become highly ferruginous and resemble the Hospital Hill slates of the Witwatersrand series. Near Pretoria duplications of the beds, due to overthrusting, are not uncommon.

The Waterberg Series lies unconformably on the Pretoria series. The colour is usually red, forcibly recalling the Old Red Sandstone and Trias of England. Sandstones, quartzites, conglomerates and breccia make up the formation. They occur to the north-east of Pretoria and occupy still wide areas in the Waterberg district.

A complex of igneous rocks of different ages covers immense areas in the central Transvaal. Various types of granite are the predominant variety. Syenites, gabbros, norites and volcanic rocks are also represented. The granite contains two varieties. One is a red granite intruded subsequently to the Waterberg sandstones; another is a grey variety considered to be older than the Black Reef series and possibly older than the Witwatersrand series.

The Karroo System attains its chief development in the south-eastern Transvaal in the districts of Ermelo, Standerton and Wakkerstroom.

The latest classification of Molengraaff subdivides the beds as follows:—

Hoogeveld Series	=	Beaufort beds of Cape Colony. Contains coal-seams.
Ecca shales.		Not present at Vereeniging.
Dwyka conglomerate.		Sandstones and conglomerates with coal-seams at Vereeniging.

The Dwyka conglomerate resembles the same bed in the Cape province. The boulders consist of very various rocks often of large size. Many of them show glacial striae. The direction of striae on the underlying quartzitic rocks, particularly well seen near the Douglas colliery, Balmoral, point to an ice movement from the north-north-west to south-south-east.

The Ecca series, as in the Cape, consists of sandstones and shales. Seams of coal lie near the base, some of them exceeding 20 ft. in thickness, but in this case layers of shaly coal are included. The overlying sandstones afford good building stones, and frequently, as at Vereeniging, yield many fossil plants. These include among others, *Glossopteris browniana, Gangamopteris cyclopteroides, Sigillaria Brardi, Bothrodendron Leslii, Noeggerathiopsis Hislopi.*

The Karroo beds lie almost horizontally, in marked contrast to the highly inclined older rocks. Their distribution, other than in the south-eastern districts, is imperfectly understood. Remnants have been found of their former existence in the neighbourhood of Pretoria; and portions of the Bushveld Sandstone have recently been relegated to the Karroo formation.

The diamond pipes probably represent some of the most recent rocks of the Transvaal. They may be of Cretaceous age or even later, and in any case belong to the same class as those of Kimberley. The recent deposits of the Transvaal may be considered to be insignificant. They include the gravels and alluviums of the present streams and the almost ubiquitous red sand of aeolian origin.[1] (W. G.*)

Climate.—Although lying on the border of and partly within the tropics, the Transvaal, owing to its high general elevation, and to the absence of extensive marshy tracts, enjoys on the whole a healthy invigorating climate, well suited to the European constitution. The climate of the high veld is indeed one of the finest in the world. The air is unusually dry, owing to the proximity of the Kalahari Desert on the west and to the interception on the east by the Drakensberg of the moisture bearing clouds from the Indian Ocean. The range of temperature is often considerable—in winter it varies from about 100° F. in the shade at 1 p.m. to freezing point at night. During summer (Oct.–April) the mean temperature is about 73°; during winter about 53°. Nov.–Jan. are the hottest and June–July the coldest months. The chief characteristic of the rainfall is its frequent intensity and short duration. During May to August there is practically no rain, and in early summer (Sept.–Dec.) the rainfall is often very light. The heaviest rain is experienced between January and April and is usually accompanied by severe thunderstorms. On the eastern escarpment of the Drakensberg the rainfall is heavy, 50 or 60 in. in the year, but it diminishes rapidly towards the centre of the plateau where it averages, at Johannesburg about 30 in.,[2] while in the extreme west as the Kalahari is approached it sinks to about 12 in. The winds in winter are uniformly dry while dust storms are frequent at all seasons—a fact which renders the country unsuitable for persons suffering from chest complaints. In the eastern part of the plateau snow occasionally falls, and frost at night is common during winter.

The banken veld district is also generally healthy though hotter than the plateaus, and malarial fever prevails in the lower valleys. Malarial fever is also prevalent throughout the low veld, but above 3000 ft. is usually of a mild type. Nearly all the country below that elevation is unsuitable for colonization by whites, while the Limpopo flats and other low tracts, including the district between the Drakensberg and the Lebombo hills are extremely unhealthy, blackwater fever being endemic. In the low veld the shade temperature in summer rises to 113° F., but the nights are generally cool, and down to 2000 ft. frost occurs in winter. The rainfall in the low country is more erratic than on the plateau, and in some districts a whole year will pass without rain.

Flora.—The general characteristic of the flora is the prevalence of herbaceous over forest growths; the high veld is covered by short sweet grasses of excellent quality for pasturage; grass is mingled with protea scrub in the middle veld; the banken veld has a richer flora, the valley levels are well wooded, scattered timber trees clothe their sides and the hills are covered with aloe, euphorbia, protea and other scrub growths. Among the timber trees of this region is the bolkenhout of terblanz (*Faurea Saligna*) which yields a fine wood resembling mahogany. The scrub which covers the low veld consists mainly of gnarled stunted thorns with flattened umbrella shaped crowns, most of the species belonging to the sub-order mimoseae. A rare species is the acacia erioloba Rameel doorn, akin to the acacia giraffae of Bechuanaland. The wild seringa (*Burkea africana*) is also characteristic of the low veld and extends up the slopes of the plateau. The meroola (*sclerocarya caffra*) a medium sized deciduous tree with a rounded spreading top is found in the low veld and up the slopes to a height of 4500 ft. It is common in the lower slopes of the rands of the low veld. Cotton and cotton-like plants and vines are also native to the low veld. Few of the low veld bushes are large or straight enough to furnish any useful wood, and timber trees are wholly absent from the level country. The forest patches are confined to the deep kloofs of the mountains, to the valleys of the larger rivers and to the sea-slopes of the Drakensberg and other ranges, where they flourish in regions exposed to the sea mists. These patches, called "wood-bushes," contain many hardwood trees of great size, their flora and fauna being altogether different from that immediately outside the wood. Common species in the woodbush are three varieties of yellow wood (*Podocarpus*), often growing to an enormous size, the Cape beech (*myrsine*), several varieties of the wild pear (*Olinia*) and of stinkwood (*Oreodaphne*) ironwood and ebony. The largest forest areas are in the Pongola district and the Haenertsburg and

Kynaston, *The Geology of the Transvaal and the Orange River Colony, Handbook, British Association* (Cape Town, 1905); *Trans. Geol. Soc. S. Africa* (Johannesburg).

[2] Exceptionally very heavy rain is experienced on the Rand. In January 1907 seven inches of rain fell in 24 hours.

Woodbush districts north of the Olifants river. Mimosa and the wild wilge-boom (*Salix capensis*) are the common trees on the banks and rivers, while the weeping willow is frequent round the farmsteads.

Many trees have been introduced and considerable plantations made, as for instance on the slopes between Johannesburg and Pretoria. Among the most successful of the imported trees are citrus trees, the Australian wattle and the eucalyptus. Tobacco and the vine both flourish and most European fruits and vegetables thrive. Of native fruits the misple (*Vangueria infausta*), miscalled the wild medlar, is of excellent flavour. It is common on the rands and kopjes of the bush veld. Rose and other flowering shrubs and trees grow well on the banken veld and in the valleys. A large yellow tulip (*Homerica pallida*) is one of the most abundant flowers on moist vlei lands on the high veld and is occasionally met with in the low veld; slangkop (*Urginea Burkei*) with red bulbs like a beetroot is a low bush plant apparently restricted to the Transvaal and adjacent Portuguese territory. Both these and many other plants such as gift-blaar and drouk-gras are poisonous to cattle. These poisonous plants are found chiefly in the banken and low veld.

Fauna.—When first entered by white men the Transvaal abounded in big game, the lion, leopard, elephant, giraffe, zebra and rhinoceros being very numerous, while the hippopotamus and crocodile were found in all the rivers. The indiscriminate destruction of these animals has greatly reduced their numbers and except in the Pongola district, at one or two other places on the Portuguese frontier, and along the Limpopo the hippopotamus, rhinoceros and crocodile are now extinct in the province. A few elephants, giraffes and zebras (*equus burchelli*—the true zebra is extinct) are still found in the north and north-eastern districts and in the same regions lions and leopards survive in fair numbers. Other animals fairly numerous are the spotted hyena, long-eared fox, jackal, aard wolf, red lynx, wild cat, wild dog and wart hog. Many species of antelope are found, mostly in small numbers, including the kudu, hartebeest, the sable and roan antelope, the white tailed and the brindled gnu, waterbuck, red buck, duiker, blesbok, palla, springbuck (numerous), steinbok, grysbok and klipspringer. The Africander breed of cattle is a well-marked variety, and a characteristic native domestic animal. Whether originally imported from Europe by the Portuguese or brought from the north by Africans is not certain. It is not found in a wild state and the buffalo (*bos caffer*) is almost if not quite extinct in the Transvaal. Among edentata the ant-bear, scaly ant-eater and porcupine are plentiful. The spring hare (*pedetes capensis*) abounds. Baboons and other apes are fairly common and there are several species of snakes. The ostrich is found in the Marico and Limpopo districts, and more rarely elsewhere; the great kori bustard and the koorhaan are common.

Insects abound, the greatest pest being the tsetse fly, common in the low veld. Six species of tick, including the blue tick common throughout South Africa, are found, especially in the low veld, where they are the means of the transmission of disease to cattle. Mosquitoes, locusts and ants are also common.

The baba or cat fish and the yellow fish are plentiful in the rivers and the trout has been acclimatized.

To preserve the native fauna the low country on the Portuguese frontier has been made a game reserve. It is nearly 300 m. long with an average breadth of 50 m. Other reserves have been constituted in the north of the province.

Inhabitants.—The population of the Transvaal, on the 17th of April 1904, when the first complete census of the country was taken, was 1,269,951 (including 8215 British soldiers in garrison),[1] or 11·342 persons per sq. m. Of these 20·67%, namely 297,277, were European or white. Of the coloured population 937,127 were aboriginals; and 35,547 were of mixed or other coloured races. Of the whites 178,244 (59·95%) were males. The white population is broadly divisible into the British and Dutch elements, the percentage of other whites in 1904 being but 8·6. The Dutch, as their usual designation, Boers, implies, are mainly farmers and stock-raisers and are still predominant elsewhere than in the Witwatersrand and Pretoria districts. They speak the patois of Dutch known as the *Taal.* The British element is chiefly gathered in Johannesburg and other towns on the Rand and in Pretoria. The total white population in the Witwatersrand and in Pretoria in 1904 was 135,135, and the strength of the British in these districts is shown by the fact that only 20% was Transvaal born. Of those born outside the Transvaal 24·6% came from other British possessions in Africa and 24·92% from Great Britain or British colonies other than African. Of the non-British or Boer whites Russians form 3·01%, Germans 1·62% and Dutch (of Holland) 1·14%.

The natives are found chiefly in Zoutpansberg district, where there were 314,797 at the 1904 census, and the adjoining districts of Lydenburg and Waterberg, *i.e.* in the northern and north-eastern region of the country. The natives belong to the Bantu negro race and are represented chiefly by Basuto, Bechuana, Bavenda, and Xosa-Zulu tribes. None of these peoples has any claim to be indigenous, and, save the Bavenda, all are immigrants since *c.* 1817–1820, when the greater part of the then inhabitants were exterminated by the Zulu chief Mosilikatze (see § *History*). After that event Basuto entered the country from the south, Bechuana from the west and Swazi, Zulu, Shangaan and other tribes from the east and south-east.

The Basuto, who number 410,020 and form 40% of the total population, are now found mostly in the central, northern and north-eastern districts, forming in Lydenburg about 67%, and in Zoutpansberg about 50% of the inhabitants. The Bechuana, who number 64,751, are almost confined to the western and south-western districts.

Next, numerically, to the Basuto and Bechuana peoples are the tribes known collectively as Transvaal Kaffirs, of whom there were 159,860 enumerated at the 1904 census. Altogether the Transvaal Kaffirs form 50% of the inhabitants of Waterberg district, 30% of Zoutpansberg district and 18% of Middelburg district. Zulus number 75,601 and form 54% of the population in Wakkerstroom district and 18% in Standerton district. Elsewhere they are very thinly represented. Swazis form more than half the total population of the Barberton and Ermelo districts and are also numerous in Wakkerstroom. In Barberton, Lydenburg and Zoutpansberg districts Shangaan and other east coast tribes are settled, 80,834 being returned as born in the Transvaal. The Shangaan are members of a Bantu tribe from the Delagoa Bay region who took refuge in the Transvaal between 1860 and 1862 to escape Zulu raids. They were for some time ruled by a Portuguese, Joao Albasini, who had adopted native customs. Since 1873 Swiss Protestant missionaries have lived among them and many of the Shangaans are Christians and civilized. Several other east coast tribes, such as the Bankuna, are of mixed Zulu and Shangaan blood. Among the mixed and other coloured races in the census returns figure 1592 Bushmen, 3597 Hottentots and 1147 Koranna; these people are found chiefly in the south-western regions and are remnants of the true aboriginal population.

Besides the tribes whose home is in the Transvaal considerable numbers of natives, chiefly members of east coast tribes, Cape Kaffirs and Zulus, go to the Witwatersrand to work in the gold and other mines. In all there were, in 1904, 135,042 Bantus in the country born elsewhere. Many east coast natives after working in the mines settle in the northern Transvaal. Of the aboriginal South Africans in the Transvaal, at the 1904 census, 77·69% were born in the Transvaal. Among the aborigines the number of females to males was 114 to 100. (See further KAFFIRS; BECHUANAS; ZULULAND; BUSHMEN; HOTTENTOTS; and for languages, BANTU LANGUAGES).

The number of Asiatics in the Transvaal in April 1904 was 12,320, including 904 Malays, natives of South Africa, and 9986 British Indians. They were nearly all domiciled in the Witwatersrand and in the towns of Pretoria and Barberton, where they are engaged mainly in trade.

Administrative Divisions and Chief Towns.—The province is divided into sixteen magisterial districts. Zoutpansberg, 25,654 sq. m.; Waterberg, 15,503 sq. m.; Lydenburg, 9868 sq. m., occupy the north and north-eastern parts of the country and include most of the low veld areas. Barberton district, 5106 sq. m., is east central. Piet Retief district (in the south-east), 1673 sq. m., lies between Swaziland and Natal. Along the southern border, going east to west from Piet Retief, are the districts of Wakkerstroom, 2128 sq. m.; Standerton, 1959 sq. m.; Heidelberg, 2410 sq. m.; Potchefstroom, 4805 sq. m.; Wolmaransstad, 2169 sq. m., and, occupying the south-western corner of the province, Bloemhof, 3003 sq. m. In the west are the districts of Lichtenburg, 4487 sq. m.; Marico, 3626 sq. m. and Rustenberg, 9511 sq. m. The central regions are divided into the districts of Witwatersrand, 1653 sq. m.; Pretoria, 6525 sq. m.; Middelburg, 4977 sq. m.; Carolina, 1877 sq. m.; Ermelo, 2995 sq. m. and Bethel, 1959 sq. m. It will be seen that twenty districts are enumerated, these being the divisions under the Boer government and still commonly used. In 1904 Bloemhof was officially included in Wolmaransstad; Bethel in Standerton; Piet Retief in Wakkerstroom, and Carolina in Ermelo. Each district is sub-divided into field-cornetcies, the cornetcies being themselves divided, where necessary, into urban and rural areas. For parliamentary purposes the districts are divided into single member constituencies. The capital of the

[1] For most purposes this military element is omitted in the census returns.

province, and of the Union is Pretoria, with a population (1904) of 36,839 (of whom 21,114 were whites). Johannesburg, the centre of the gold-mining industry, had a population, within the municipal boundary, of 155,642 (83,363 whites). Other towns within the Witwatersrand district are Germiston (29,477), Boksburg (14,757) and Roodepoort-Maraisburg (19,949), virtually suburbs of Johannesburg, and Krugersdorp (20,073) and Springs (5270), respectively at the western and east ends of the district. Besides Pretoria and the towns in the Witwatersrand district, there are few urban centres of any size. Potchefstroom, in the south near the Vaal (pop. 9348), is the oldest town in the Transvaal. Klerksdorp (4276) is also near the Vaal, S.S.W. of Potchefstroom. Middelburg (5085) is the largest town on the railway between Pretoria and Delagoa Bay; Barberton (2433), the centre of the De Kaap gold-fields, lies on the slopes of the Drakensberg overlooking the De Kaap valley.

Communications.—Before 1888 the only means of communication was by road. In that year the government sanctioned the building of a "steam tramway"—a railway in all but name—from the Boksburg collieries to the Rand gold mines. In 1890 the construction of the Transvaal section of the railway to connect Pretoria with Delagoa Bay was begun, the line from Lourenço Marques having been completed to Komati Poort in December 1887. The line to Pretoria was not opened until July 1895. Meantime, in September 1892, the Cape railway system had been extended to Johannesburg and in December 1895 the through line between Durban and Pretoria was completed. Since that date many other lines have been built. The majority of the railways are the property of and are worked by the state. With the exception of a few purely local lines they are of the standard South African gauge—3 ft. 6 in. The lines all converge on Johannesburg. The following table gives the distances from that city to other places in South Africa[1]:—

Inland Centres—		
To Pretoria	46	miles.
,, Kimberley	310	,,
,, Bloemfontein	263	,,
,, Bulawayo (via Fourteen Streams)	979	,,
,, Salisbury (,, ,,)	1279	,,
Seaports—		
To Cape Town (via Kimberley)	957	,,
,, ,, (via Bloemfontein)	1013	,,
,, Port Elizabeth	714	,,
,, East London	665	,,
,, Durban	483	,,
,, Lourenço Marques (via Pretoria)	396	,,

Besides the lines enumerated the other railways of importance are: (1) A line from Johannesburg eastward via Springs and Breyten to Machadodorp on the Pretoria-Delagoa Bay railway. (2) A line, 68 m. long from Witbank, a station on the Pretoria-Delagoa Bay line, to Brakpan on the Springs line. By (1) the distance between Johannesburg and Lourenço Marques is 364 m., by (2) 370 m. A continuation of the Springs-Breyten line eastward through Swaziland to Delagoa Bay will give a second independent railway from that port to the Rand, some 60 m. shorter than the route via Pretoria, while from Breyten a line (90 m. long) runs south and east to Ermelo and Piet Retief. (3) A line from Krugersdorp to Zeerust (128 m.). (4) A line from Pretoria to Rustenburg (61 m.). (5) A line from Pretoria to Pietersburg (177 m.). This line was continued (1910) north-west to effect a junction with (6) the "Selati" railway, which, starting from Komati Poort, runs north-west and was in 1910 continued to Leydsdorp. North of the junction with the Pietersburg line the railway goes towards the Limpopo. (7) A line from Belfast on the Pretoria-Delagoa Bay railway to Lydenburg (65 m.). (8) A line from Potchefstroom to Lichtenburg (70 m.).

There is an extensive telegraphic system linking the towns of the province to one another, and, through the surrounding countries, with Europe and the rest of the world. There is inland communication via Rhodesia with British Central Africa and Ujiji on Lake Tanganyika. The telegraph lines within the Transvaal have a length of about 3000 m. There is a well-organized postal service with about 400 offices. In connexion with the postal services to outlying districts there is a public passenger service by mailcarts. In the Pietersberg district zebras are occasionally employed.

Mineral Resources.—The Transvaal, the principal gold producing country in the world, is noted for the abundance and variety of its mineral resources. The minerals chiefly mined besides gold are diamonds and coal, but the country possesses also silver, iron, copper, lead, cobalt, sulphur, saltpetre and many other mineral deposits.

Gold.—The principal gold-bearing reefs are found along the Witwatersrand ("The Rand"). Probably connected with the Rand reefs are the gold-bearing rocks in the Klerksdorp, Potchefstroom and Venterskroon districts. Other auriferous reefs are found all along the eastern escarpment of the Drakensberg and are worked in the De Kaap (Barberton) district, on the Swaziland frontier, in the Lydenburg district, in the Murchison Range and in other places in the Zoutpansberg. Goldfields also exist in the Waterberg and on the western frontier in the Marico district (the Malmani fields). The total value of the gold extracted from mines in the Transvaal up to the end of 1909 was about £246,000,000.

a. The Witwatersrand and Neighbouring Mines.—The Rand reefs, first mined in 1886, cover a large area. The main reef, continuously traced, measures about 62 m. and runs in an east and west direction. The gold is found in minute particles and in the richest ores the metal is rarely in visible quantities before treatment. In many places the main reef lies at a great depth and some bore-holes are over 5500 ft. deep. The yield of the Rand mines, in 1887 but 23,000 oz.. rose in 1888 to 208,000 oz. In 1892 the yield was 1,210,000 oz.: in 1896 it exceeded 2,280,000 oz. and in 1898 was 4,295,000 oz. The war that followed prevented the proper working of the mines. In 1905 when a full supply of labour was again available the output was 4,760,000 oz., in which year the sum distributed in dividends to shareholders in the Rand mines was over £4,800,000. The total output from the Rand mines up to the end of 1908 was 56,477,240 oz. (see GOLD, and JOHANNESBURG). The Klerksdorp and Potchefstroom goldfields, known also as the Western Rand, were proclaimed in 1887 and up to the close of 1908 had yielded 446,224 oz.

b. The De Kaap (Barberton) Fields.—Gold was discovered in this district of the Drakensberg in 1875, but it was not until 1884 that the fields attracted much attention. The mines are, in general, situated on the slopes of the hills and are easily opened up by adits. The reefs are narrower than those of the Rand, and the ore is usually very hard. The output, 35,000 oz. in 1889, was 121,000 oz. in 1896, but only 43,000 oz. in 1905. The total production (including the Komati and Swaziland fields) to the end of 1908 was 1,097,685 oz.

c. The Lydenburg and other Fields.—The Lydenburg fields, reported to have been worked by the Portuguese in the 17th century, and rediscovered in 1869, though lying at an elevation of 4500 to 5000 ft. are alluvial—and the only rich alluvial goldfields in South Africa. The ground containing the gold is soil which has escaped denudation. Though several large nuggets have been found (the largest weighing 215 oz.), the total production is not great, the highest output obtained by washing being worth about £300,000 in one year. Besides the alluvial deposits a little mining is carried on, gold being present in the thin veins of quartz which cross the sandstone. The chief centres of the fields are Lydenburg, Pilgrims Rest and Spitzkop. The total output of the Lydenburg fields up to the end of 1908 is estimated at 1,200,000 oz. Farther north, in the Zoutpansberg and on its spurs are the little-worked mines generally known as the Low Country goldfields. Near Pietersburg in the Zoutpansberg is the Eersteling, the first mine worked in the Transvaal. Operations began in 1873 but in 1880 the machinery was destroyed by the Boers. It was not until 1904 that prospecting in the neighbourhood was again undertaken. The fields in the Waterberg and along the Malmani river are very small producers. The total yield to the end of 1908 of the Zoutpansberg, Low Country and other minor fields was 160,535 oz.

Diamonds.—The chief diamond fields are in the Pretoria district. The ground was discovered to be diamondiferous in 1897, but it was not until 1903, when mining began on the Premier mine, situated 20 m. north-east of Pretoria, that the wealth of the fields was proved. The site of the Premier mine had been recognized as diamond-bearing in March 1898. The owner of the land, a Boer named Prinsloo, refused to allow experimental spade work, but after the conclusion of the Anglo-Boer War in 1902 sold his property for £55,000 to T. Cullinan (a Cape colonist and one of the chief contractors in the building of Johannesburg), whose faith in the richness of the ground was speedily justified. In June 1903 mining began and the diamonds found in the first five months realized over £90,000. On the 27th of January 1905, the largest diamond in the world, weighing 3025¾ carats, over 1½ lb avoirdupois, was found in the mine and named the Cullinan. The Premier mine is of the same character as the diamond mines at Kimberley (see DIAMOND), and is considerably larger. The area of the "pipe" containing blue ground is estimated at 350,000 sq. yds.

Besides the Pretoria fields there are diamondiferous areas (alluvial diggings) in the Bloemhof district on the Vaal river north-east of Kimberley, and in other regions. In 1898 the output for the whole of the Transvaal was valued at £44,000. The output since the opening of the Premier mine has been: 1903–1904, £685,720; 1904–1905, £1,198,530; 1905–1906, £968,229; 1906–1907, £2,203,511; 1907–1908, £1,879,551; 1908–1909, £1,295,296.

Coal and other Minerals.—There are extensive beds of good coal, including thick seams of steam coal near the Rand and other goldfields. Coal appears to have been first discovered in the neighbourhood of Bronkhorst Spruit between the Wilge and Olifants rivers, where it was so near the surface that farmers dug it up for their own use. In 1887 coal was found at Boksburg in the East Rand, and a mine was at once started. The principal collieries are those

[1] For projected routes, shortening the journey between Europe and Johannesburg, see the *Geog. Journ.*, Dec. 1910.

at Boksburg and at Brakpan, also on the East Rand, with a coal area of 2400 acres; at Vereeniging and Klerksdorp, near the Vaal; at Watervaal, 12 m. north of Pretoria; and in the Middelburg district, between Pretoria and Lourenço Marques. Like that of Natal the Transvaal coal burns with a clear flame and leaves little ash. The mines are free from gas and fire damp and none is more than 500 ft. deep. The output in 1893, the first year in which statistics are available, was 548,534 tons (of 2000 lb); in 1898 it was 1,907,808 tons, and for the year ending 30th of June 1909 was 3,312,413 tons, valued at £851,150.

Iron and copper are widely distributed. The Yzerberg near Marabastad in the Zoutpansberg consists of exceedingly rich iron ore, which has been smelted by the natives for many centuries. Silver is found in many districts, and mines near Pretoria have yielded in one year ore worth £30,000.

Salt is obtainable from the many *pans* in the plateaus, notably in the Zout(salt)pansberg, and was formerly manufactured in considerable quantities.

Agriculture.—Next to mining agriculture is the most important industry. At the census of 1904 over 500,000 persons (excluding young children), or 37 % of the population, were returned as engaged in agriculture. Some 25 % more women than men were so employed, this preponderance being due to the large number of Kaffir women and the few native men who work in the mealie fields. The chief occupation of the majority of the white farmers is stock-raising. The high veld is admirably adapted for the raising of stock, its grasses being of excellent quality and the climate good. Even better pasture is found in the low veld, but there stock suffers in summer from many endemic diseases, and in the more northerly regions is subject to the attack of the tsetse fly. The banken veld is also unsuited in summer for horses and sheep, though cattle thrive. Much of the stock is moved from the lower to the higher regions according to the season. Among the high veld farmers the breeding of merino sheep is very popular.

The amount of land under cultivation is very small in comparison with the area of the province. In 1904 only 951,802 acres, or 1·26 % of the total acreage was under cultivation, and of the cultivated land nearly half was farmed by natives. The small proportion of land tilled is due to many causes, among which paucity of populations is not the least. Moreover while large areas on the high veld are suitable for the raising of crops of a very varied character, in other districts, including a great part of the low veld, arable farming is impossible or unprofitable. Many regions suffer permanently from deficient rainfall; in others, owing to the absence of irrigation works, the water supply is lost, while the burning of the grass at the end of summer, a practice adopted by many farmers, tends to impoverish the soil and render it arid. The country suffers also from periods of excessive heat and general drought, while locusts occasionally sweep over the land, devouring every green thing. In some seasons the locusts, both red and brown, come in enormous swarms covering an area 5 m. broad and from 40 to 60 m. long. The chief method employed for their destruction is spraying the swarms with arsenic. The districts with the greatest area under cultivation are Heidelberg, Witwatersrand, Pretoria, Standerton and Krugersdorp. The chief crops grown for grain are wheat, maize (mealie) and kaffir corn, but the harvest is inadequate to meet local demands. Maize is the staple food of the Kaffirs. Since 1906 an important trade has also arisen in the raising of mealies for export by white farmers. Oats, barley and millet are largely grown for forage. Oats are cut shortly before reaching maturity, when they are known as oat-hay. The chief vegetables grown are potatoes, pumpkins, carrots, onions and tomatoes.

Fruit farming is a thriving industry, the slopes of the plateaus and the river valleys being specially adapted for this culture. At the census of 1904 over 3,032,000 fruit trees were enumerated. There were 163,000 orange trees and nearly 60,000 other citrus trees, 430,000 grape vines, 276,000 pine plants and 78,000 banana plants. Oranges are cultivated chiefly in the Rustenburg, Waterberg, Zoutpansberg and Pretoria districts, grapes in Potchefstroom, Pretoria and Marico, as well as in the Zoutpansberg and Waterberg, to which northern regions the cultivation of the banana is confined. In the tropical district of the Limpopo valley there is some cultivation of the coffee-tree, and this region is also adapted for the growing of tea, sugar, cotton and rice. Tobacco is grown in every district, but chiefly in Rustenburg. Of the 3,032,000 lb of tobacco grown in 1904, Rustenburg produced 884,000 lb.

A department of agriculture was established in 1902, and through its efforts great improvements have been made in the methods of farming. To further assist agriculture a land bank was established by the government in 1907 and an agricultural college in 1910.

Land Settlement.—The land board is a government department charged with the control of Crown lands leased to settlers on easy terms for agricultural purposes. Between 1902 and 1907 about 550 families were placed on the land, their holdings aggregating over 500,000 acres. The Crown lands cover in all about 21,500,000 acres. Large areas of these lands, especially in the northern districts, are used as native reserves.

Other Industries.—There are few manufacturing undertakings other than those connected with mining, agriculture and the development of Johannesburg. There is a large factory for the supply of dynamite to the gold mines. The building and construction trade is an important industry on the Rand, where there are also brick-works, iron and brass foundries, breweries and distilleries. There are a number of flour mills and jam factories in various centres. A promising home industry, started under English auspices after the war of 1899–1902, is the weaving by women of rugs, carpets, blankets, &c., from native wool.

Export and Import Trade.—Before the discovery of gold the trade of the Transvaal was of insignificant proportions. This may be illustrated by the duties paid on imports, which in 1880 amounted to £20,306. In 1887 when the gold-mining industry was in its infancy the duty on imports had risen to £190,792, and in 1897, when the industry was fully developed, to £1,289,039. The Anglo-Boer War completely disorganized trade, but the close of the contest was marked by feverish activity and the customs receipts in 1902–1903 rose to £2,176,658. A period of depression followed, the average annual receipts for the next three years being £1,683,159. In 1908–1909 they were £1,588,960.

The chief exports are gold and diamonds. Of the total exports in 1908, valued at £33,323,000, gold was worth £29,643,000 and diamonds £1,977,000. Next in value came wool (£226,000), horses and mules (£110,000), skins, hides and horns (£106,000), tobacco (£89,000), tin, coal, copper and lead. The gold and diamonds are sent to England via Cape Town; the other exports go chiefly to Delagoa Bay. The imports, valued at £16,196,000 in 1908, include goods of every kind. Machinery, provisions, largely in the form of tinned and otherwise preserved food, and liquors, clothing, textiles and hardware, chemicals and dynamite, iron and steel work and timber, and jewelry are the chief items in the imports. Of the imports about 50 % comes from Great Britain and about 20 % from British colonies (including other South African states). Half the imports reach the Transvaal through the Portuguese port of Lourenço Marques, Durban taking 25 % and the Cape ports the remainder. There is free trade between the Transvaal and the other British possessions in South Africa, and for external trade they all adhere to a Customs Union which, as fixed in 1906, imposes a general *ad valorem* duty of 15 % on most goods save machinery, on which the duty is 3 %. A rebate of 3 % is granted on imports from Great Britain.

Constitution.—The existing constitution dates from 1910. The province is represented in the Union Parliament by eight senators and thirty-six members of the House of Assembly. For parliamentary purposes the province is divided into single-member constituencies. Every adult white male British subject is entitled to the franchise, subject to a six months' residential qualification.[1] There is no property qualification. All electors are eligible to the assembly. Voters are registered biennially, and every five years there is an automatic redistribution of seats on a voters' basis.

Central Government.—At the head of the executive is a provincial administrator, appointed by the Union ministry, who holds office for five years and is assisted by an executive committee of four members elected by the provincial council. The provincial council consists of 36 members elected for the same constituencies and by the same electorate as are the members of the House of Assembly. The provincial council, which has strictly local powers, sits for a statutory period of three years. The control of elementary education was guaranteed to the provincial council for a period of five years from the establishment of the Union.

In May 1903 an inter-colonial council was established to deal with the administration of the railways in the Transvaal and Orange River Colony (known as the Central South African railways), the South African constabulary and other matters common to the Orange River and Transvaal colonies. This council was presided over by the governor of the Transvaal and formed an important part of the administrative machinery. By agreement between the two colonies the council was dissolved in 1908. In 1910 the control of the railways passed to the harbours and railway board of the Union of South Africa.

Local Government.—The unit of administration is the field cornetcy. The semi-military organization of these divisions, which existed under the South African republic, has been abolished, and field-cornets, who are nominated by the provincial government, are purely civil officials charged with the registration of voters, births and deaths, the maintenance of public roads, &c. The chief local authorities are the municipal bodies, many "municipalities" being rural areas centred round a small town. The municipal boards possess very

[1] The number of electors at the first registration (1907) was 105,368.

wide powers of local government. The Witwatersrand municipalities are for certain purposes combined into one authority, and representatives of these municipalities, together with representatives of the chamber of mines, compose the Rand water board. The basis of municipal qualification is ownership of real property of the value of £100, or the tenancy of premises of the value of £300, or annual value of £24. Neither aliens nor coloured British subjects can exercise the franchise.

Finance.—In 1883, before the Rand gold mines had been found revenue and expenditure were about £150,000; in 1887, when the mines were beginning to be developed, the receipts were £668,000 and the expenditure £721,000; in 1889 the receipts had risen to £1,577,000 and the expenditure to £1,226,000. In 1894 the receipts first exceeded two millions, the figures for that year being: revenue £2,247,000, expenditure £1,734,000. The figures for the four following years were:—

	Revenue.	Expenditure.
1895	£3,539,000	£2,679,000
1896	£4,807,000	£4,671,000
1897	£4,480,000	£4,394,000
1898	£3,983,000	£3,971,000

The public debt of the Boer government was £2,500,000. In 1899 war broke out and the finances of the country were disorganized. The accounts of the colony began, for normal purposes, with the year ending 30th of June 1903, and ended in June 1910 on the establishment of the Union. In May 1903 a loan of £35,000,000, guaranteed by the imperial government and secured on the general revenues of the Transvaal and Orange River colonies, was issued to the extent of £30,000,000, the balance being raised about the middle of 1904. This loan bears interest at 3% per annum, with a sinking fund of 1%, and as to the £30,000,000 was issued at par, the £5,000,000 being put up to tender and realizing an average price of £98, 10s. 3d. The principal head in the allocation of this loan was the purchase of the railways in the two colonies at a cost of £13,520,000, while an additional £5,958,000 was devoted to the building of new lines, purchases of rolling stock, &c. The debt of the South African Republic was paid off; £542,000 went to make good the deficit on the administration for 1901–1902; the sum of £1,561,000 was paid to burghers of the Cape Colony and Natal as compensation for war losses; £3,000,000 was devoted to land settlement schemes and £2,000,000 to public works other than railways. The railways were treated as the common property of both colonies, and to administer them and other common services the inter-colonial council was created. In addition to the charges enumerated £5,000,000 were spent out of the loan on "repatriation and compensation" of burghers who had suffered during the war.[1] In addition to the £35,000,000 guaranteed loan of 1903–1904 two small loans for land settlement and public works, together amounting to £254,800, were issued, and in 1907 an imperial guarantee was given for the raising of another loan, of £5,000,000, by the colonial government. The act authorizing the loan devoted £2,500,000 to the establishment of a land and agricultural bank, and £2,500,000 to railways, public works, irrigation and agricultural settlement and development. The loan was raised, as to £4,000,000, in January 1909, the average price obtained being £96, 3s. 7d.

The chief sources of revenue are customs, mining royalties, railways, native revenue (poll tax and passes), posts and telegraphs, stamp and transfer duties, land revenue and taxes on trades and professions. A tax of 10% is levied on the annual net produce of all gold workings (proclamation of 1902) and the government takes 60% of the profits on diamond mines. In 1907 an excise duty was, for the first time, levied on beer. The principal heads of expenditure are on railways and other public works, including posts and telegraphs, justice, education, police, land settlement and agriculture generally, mines and native affairs. Since June 1910 the control of state finance passed to the Union parliament, but the Transvaal provincial council is empowered to raise revenue for provincial purposes by direct taxation and, with the consent of the Union government, to borrow money on the sole credit of the province.

In the five years 1902–1907 the average annual receipts and expenditure amounted to £4,500,000, exclusive of the sums received and expended on account of the loans mentioned. The inter-colonial council received and spent in the four years 1903–1907 over £21,500,000, including some £3,500,000 paid in from revenue by the Transvaal and Orange River colonies to make good deficits. Fully two-thirds of the revenue and expenditure of the Council was derived from and spent upon the Transvaal, so that had the accounts of the two colonies been entirely distinct the figures of the Transvaal budget for 1903–1907 would have balanced at about £8,500,000 a year. In July 1907 when the control of the finances passed into the hands of the Transvaal legislature the credit balance on the consolidated fund was £960,000. In 1908 the inter-colonial council was dissolved, but the railways continued to be administered as a joint concern by a railway board on which the governments of both colonies were represented. This board in 1910 handed over its duties to the harbour and railway board of the Union. The Transvaal revenue (apart from railway receipts) in 1908–1909 was £5,735,000, the corresponding expenditure £4,524,000. The budget figures for 1909–1910 were: revenue £5,943,000; expenditure £5,231,000. The diamond revenue yielded £235,000 and the gold profits tax £965,000. The balance handed over to the Union government was £1,015,000.

[1] Besides this £5,000,000 an additional sum of £9,500,000 was spent by the imperial government in relieving the necessities of those who had suffered during the war, but of this £9,500,000 the sum of £2,500,000 was in payment for goods received.

Justice.—The laws are based on Roman-Dutch law, as modified by local acts. Courts of first instance are presided over by magistrates, the whole colony being divided into sixteen magisterial wards. There is a provincial division of the Supreme Court of South Africa sitting at Pretoria (consisting of a judge president and six puisne justices) with original and appellate jurisdiction in civil and criminal matters. A local division of the Supreme Court, formerly known as the Witwatersrand high court (consisting of one or more judges of the Supreme Court) sits permanently at Johannesburg and has civil and criminal jurisdiction throughout the Rand. Circuit courts are held as occasion requires.

Police.—Pretoria and Johannesburg have their own police forces. The rest of the province is policed by the South African constabulary, a body 3700 strong, to which is also entrusted customs preventive work, fire brigade work and such like functions.

Education.—Since 1910 education other than elementary is under the control of the Union parliament. The provincial council is responsible for elementary education. At the head of the permanent staff is a director of education. School boards and district committees are formed, but their functions are almost entirely advisory. In accordance with the terms of the Education Act of 1907 of the Transvaal colony, state schools are provided for the free instruction of all white children in elementary subjects. Attendance at school between the ages of 7 and 14 is, with certain exceptions, compulsory. The medium of instruction in the lower standards is the mother tongue of the children. Above standard III. English is the medium of instruction. No religious tests are imposed on teachers and religious teaching is confined to undenominational Bible teaching. No government grants are given to private schools. (In 1906 members of the Dutch community established a "Christian National Education" organization and opened a number of denominational schools.) Secondary education is provided in the towns and high schools are maintained at Pretoria, Johannesburg and Potchefstroom. There are University colleges at Pretoria and Johannesburg. Education of the natives is chiefly in the hands of the missionaries, but the government gives grants in aid to over 100 schools for natives. At the census of 1904 the natives able to read formed less than 1% of the population. At the same census 95% of the white population over 21 were able to read and write; of the whites between the ages of 5 and 14 59% could read and write.

State schools for white children were established by the Boer government, and in the last year (1898) before the British occupation there were 509 schools and 14,700 scholars, the education vote that year being £226,000. In 1902 the property vested in various school committees was transferred to government and control of the schools vested in a department of state. In 1909 there were 670 government elementary schools, with more than 42,000 scholars. In 1907–1908 the education vote exceeded £500,000.

Religion.—Of the total population 26·69% are Christians, and of the Christians 80% are whites. No fewer than 70% of the people, including the bulk of the natives, are officially returned as of "no religion." Of the 336,869 Christians 69,738 were natives. Nearly half of the white community, 142,540 persons, belong to one or other of the Dutch Churches in the Transvaal, but they have only 4305 native members. Of Dutch Churches the first and chief is the Nederduitsch Hervormde Kerk, founded by the Voortrekkers and originally the state Church. The others are the Nederduitsch Gereformeerde Kerk, an offshoot of the Church of the same name at the Cape, and the Gereformeerde Kerk (the "Dopper" Church) with some 15,000 members and adherents in the Transvaal. The "Dopper" Church, an offshoot of the Separatist Reformed Church of Holland, is distinguished from the other Dutch churches in being more rigidly Calvinistic and "Biblical," and in not using hymns. A "Scouts" Church was formed at the end of the war of 1899–1902 by burghers who had previously acted as "National Scouts" and were ostracized by the synods of their former Churches. After some years of friction "National Scouts" were however readmitted, on terms, to their former membership.

The Anglicans number 67,882 (including 13,033 natives), and are 19% of the European population. At the head of the community is the bishop of Pretoria. Next in numbers according to European membership among the Protestant bodies are Presbyterians, 19,821 (including 1194 natives), and Methodists 37,812 (including 20,648 natives). The Lutherans are the chief missionary body. Of a total membership of 24,175 only 5770 are European. The Protestant European community amounts altogether to 35% of the white population. The Roman Catholics number 16,453 (including 2005 natives) and form 5% of the European population, and the Hebrews 15,478 or 5·34% of the European inhabitants.

Defence.—A strong garrison of the British army is maintained in the province, the headquarters of all the imperial military forces in South Africa being at Pretoria. These forces are under the command of a lieutenant-general, who, however, acts under the supreme direction of the governor-general. The Transvaal forms a distinct district command under a major-general.

A volunteer force was established in 1904, for service within the Transvaal, or wherever the interests of the country might require. The force, disciplined and organized by a permanent staff of officers and non-commissioned officers of the regular army, is about 6500 strong, and consists of a brigade of artillery, four mounted, three composite and four infantry corps, a cyclist corps, &c. There are also cadet companies some 3000 strong. (F. R. C.)

History

A. *Foundation of the Republic.*—At the beginning of the 19th century the country now known as the Transvaal was inhabited, apparently somewhat sparsely, by Bavenda and other Bantu negroes, and in the south-west by wandering Bushmen and Hottentots. About 1817 the country was invaded by the chieftain Mosilikatze and his impis, who were fleeing from the vengeance of Chaka, king of the Zulus. The inhabitants were unable to withstand the attacks of the disciplined Zulu warriors—or Matabele, as they were henceforth called—by whom large areas of central and western Transvaal were swept bare. The remnants of the Bavenda retreated north to the Waterberg and Zoutpansberg, while Mosilikatze made his chief kraal at Mosega, not far from the site of the town of Zeerust. At that time the region between the Vaal and Limpopo was scarcely known to Europeans. In 1829, however, Mosilikatze was visited at Mosega by Robert Moffat, and between that date and 1836 a few British traders and explorers visited the country and made known its principal features. Such was the situation when Boer emigrants first crossed the Vaal.

The causes which led to the exodus of large numbers of Dutch farmers from Cape Colony are discussed elsewhere (see South Africa and Cape Colony). Here it is only necessary to state that the *Voortrekkers* were animated by an intense desire to be altogether rid of British control, and to be allowed to set up independent communities and govern the natives in such fashion as they saw fit. The first party to cross the Vaal consisted of 98 persons under the leadership of Louis Trichard and Jan van Rensburg. They left Cape Colony in 1835 and trekked to the Zoutpansberg. Here Rensburg's party separated from the others, but were soon afterwards murdered by natives.[1] Trichard's party determined to examine the country between the Zoutpansberg and Delagoa Bay. Fever carried off several of their number, and it was not until 1838 that the survivors reached the coast. Eventually they proceeded by boat to Natal. Meantime, in 1836, another party of farmers under Andries Hendrik Potgieter had established their headquarters on the banks of the Vet river. Potgieter and some companions followed the trail of Trichard's party as far as the Zoutpansberg, where they were shown gold workings by the natives and saw rings of gold made by native workmen. They also ascertained that a trade between the Kaffirs and the Portuguese at Delagoa Bay already existed. On returning to the Vet, Potgieter learned that a hunting party of Boers which had crossed the Vaal had been attacked by the Matabele, who had also killed Boer women and children. This act led to reprisals, and on the 17th of January 1837 a Boer commando surprised Mosilikatze's encampment at Mosega, inflicting heavy loss on the Matabele without themselves losing a man. In November of the same year Mosilikatze suffered further heavy losses at the hands of the Boers, and early in 1838 he fled north beyond the Limpopo, never to return. Potgieter, after the flight of the Matabele, issued a proclamation in which he declared the country which Mosilikatze had abandoned forfeited to the emigrant farmers. After the Matabele peril had been removed, many farmers trekked across the Vaal and occupied parts of the district left derelict. Into these depopulated areas there was also a considerable immigration of Basuto, Bechuana and other Bantu tribes.

Potgieter.

The first permanent white settlement north of the Vaal was made by a party under Potgieter's leadership. That commandant had in March 1838 gone to Natal, and had endeavoured to avenge the massacre of Piet Retief and his comrades by the Zulus. Jealous, however, of the preference shown by the Dutch farmers in Natal to another commandant (Gert Maritz), Potgieter speedily recrossed the Drakensberg, and in November 1838 he and his followers settled by the banks of the Mooi river, founding a town named Potchefstroom in honour of Potgieter. This party instituted an elementary form of government, and in 1840 entered into a loose confederation with the Natal Boers, and also with the Boers south of the Vaal, whose headquarters were at Winburg. In 1842, however, Potgieter's party declined to go to the help of the Natal Boers, then involved in conflict with the British. Up to 1845 Potgieter continued to exercise authority over the Boer communities on both sides of the Vaal. A determination to keep clear of the British and to obtain access to the outer world through an independent channel led Potgieter and a considerable number of the Potchefstroom and Winburg burghers in 1845 to migrate towards Delagoa Bay. Potgieter settled in the Zoutpansberg, while other farmers chose as headquarters a place on the inner slopes of the Drakensberg, where they founded a village called Andries Ohrigstad. It proved fever-ridden and was abandoned, a new village being laid out on higher ground and named Lydenburg in memory of their sufferings at the abandoned settlement.

The Sand River Convention.

Meantime the southern districts abandoned by Potgieter and his comrades were occupied by other Boers. These were joined in 1848 by Andries W. J. Pretorius (*q.v.*), who became commandant of the Potchefstroom settlers. When the British government decided to recognize the independence of the Transvaal Boers it was with Pretorius that negotiations were conducted. On the 17th of January 1852 a convention was signed at a farm near the Sand river in the Orange sovereignty by assistant commissioners nominated by the British high commissioner on the one hand, and by Pretorius and other Boers on the other. The first clause was in the following terms:—

> The assistant commissioners guarantee in the fullest manner, on the part of the British government, to the emigrant farmers beyond the Vaal river, the right to manage their own affairs, and to govern themselves according to their own laws, without any interference on the part of the British government, and that no encroachment shall be made by the said government on the territory beyond to the north of the Vaal river, with the further assurance that the warmest wish of the British government is to promote peace, free trade, and friendly intercourse with the emigrant farmers now inhabiting, or who hereafter may inhabit, that country; it being understood that this system of non-interference is binding upon both parties.

At this time there were settled north of the Vaal about 5000 families of European extraction—about 40,000 persons, including young children. They had obtained independence, but they were far from being a united people. When Pretorius conducted the negotiations which led to the signing of the Sand River Convention he did so without consulting the volksraad, and Potgieter's party accused him of usurping power and aiming at domination over the whole country. However, the volksraad, at a meeting held at Rustenburg on the 16th of March 1852, ratified the convention, Potgieter and Pretorius having been publicly reconciled on the morning of the same day. Both leaders were near the end of their careers; Potgieter died in March and Pretorius in July 1853.

Whatever their internal dissensions the Boers were united

[1] Two small children were spared and brought up as Kaffirs. In 1867 they were given over to the Boer government by the Swazis, who had acquired them from their captors.

in regard to what they considered their territorial rights, and in the interval between the signing of the Sand River Convention and the death of Pretorius an incident occurred significant alike of their claims to jurisdiction over enormous areas and of their manner of treating the natives. Within a few weeks of the signing of the convention Pretorius had asked the British authorities to close the "lower road" to the interior, that is the route through Bechuanaland, opened up by Moffat, Livingstone and other missionaries. Pretorius alleged that by this means the natives were obtaining firearms. At the same time the Transvaal Boers claimed that all the Bechuana country belonged to them, a claim which the British government of that day did not think it worth while to contest. No boundary westward had been indicated in the Sand River Convention. The Barolong, Bakwena and other Bechuana tribes, through whose lands the "lower road" ran, claimed however to be independent, among them Sechele (otherwise Setyeli), at whose chief kraal—Kolobeng—Livingstone was then stationed. Sechele was regarded by the Boers as owing them allegiance, and in August 1852 Pretorius sent against him a commando (in which Paul Kruger served as a field cornet), alleging that the Bakwena were harbouring a Bakatla chief who had looted cattle belonging to Boer farmers. It was in this expedition that Livingstone's house was looted. There was little fighting, but the commando carried off between two and three hundred native women and children—some of whom were redeemed by their friends, and some escaped, while many of the children were apprenticed to farmers. Sechele's power was not broken, and he appealed for British protection, which was not then granted. The incident was, however, but the first step in the struggle for the possession of that country (see BECHUANALAND). It served to strengthen the unfavourable impression formed in England of the Transvaal Boers with regard to their treatment of the natives; an impression which was deepened by tidings of terrible chastisement of tribes in the Zoutpansberg, and by the Apprentice Law passed by the volksraad in 1856—a law denounced in many quarters as practically legalizing slavery.

On the death of Andries Pretorius his son Marthinus W. Pretorius (*q.v.*) had been appointed his successor, and to the younger Pretorius was due the first efforts to end the discord and confusion which prevailed among the burghers—a discord heightened by ecclesiastical strife, the points at issue being questions not of faith but of church government. In 1856 a series of public meetings, summoned by Pretorius, was held at different districts in the Transvaal for the purpose of discussing and deciding whether the time had not arrived for substituting a strong central government in place of the petty district governments which had hitherto existed. The result was that a representative assembly of delegates was elected, empowered to draft a constitution. In December this assembly met at Potchefstroom, and for three weeks was engaged in modelling the constitution of the country. The name "South African Republic" was adopted as the title of the state, and the new constitution made provision for a volksraad to which members were to be elected by the people for a period of two years, and in which the legislative function was vested. The administrative authority was to be vested in a president, aided by an executive council. It was stipulated that members both of the volksraad and council should be members of the Dutch Reformed Church, and of European blood. No equality of coloured people with the white inhabitants would be tolerated either in church or state. In reviewing an incident so important in the history of the Transvaal as the appointment of the Potchefstroom assembly it is of interest to note the gist of the complaint among the Boers which led to this revolution in the government of the country as it had previously existed. In his *History of South Africa* Theal says: "The community of Lydenburg was accused of attempting to domineer over the whole country, without any other right to pre-eminence than that of being composed of the earliest inhabitants, a right which it had forfeited by its opposition to the general weal." In later years this complaint was precisely that of the Uitlanders at Johannesburg. To conciliate the Boers of Zoutpansberg the new-born assembly at Potchefstroom appointed Stephanus Schoeman, the commandant-general of the Zoutpansberg district, commandant-general of the whole country. This offer was, however, declined by Schoeman, and both Zoutpansberg and Lydenburg indignantly repudiated the new assembly and its constitution. The executive council, which had been appointed by the Potchefstroom assembly, with Pretorius as president, now took up a bolder attitude: they deposed Schoeman from all authority, declared Zoutpansberg in a state of blockade, and denounced the Boers of the two northern districts as rebels.

Potchefstroom Assembly, 1856.

Further to strengthen their position, Pretorius and his party unsuccessfully endeavoured to bring about a union with the Orange Free State. Peaceful overtures having failed, Pretorius and Paul Kruger placed themselves at the head of a commando which crossed the Vaal with the object of enforcing union, but the Free State compelled their withdrawal (see ORANGE FREE STATE). Within the Transvaal the forces making for union gained strength notwithstanding these events, and by the year 1860 Zoutpansberg and Lydenburg had become incorporated with the republic. Pretoria, newly founded, and named in honour of the elder Pretorius, was made the seat of government and capital of the country. The ecclesiastical efforts at unity had not been equally successful. The Separatist Reformed Church of Holland had sent out a young expositor of its doctrines named Postma, who, in November 1858, became minister of Rustenburg. In the following year a general church assembly endeavoured to unite all the congregations in a common government, but Postma's consistory rejected these overtures, and from that date the Separatist (or Dopper) Church has had an independent existence (see *ante*, § *Religion*). Paul Kruger, who lived near Rustenburg, became a strong adherent of the new church.

Presidency of Marthinus Pretorius.

Pretorius, while still president of the Transvaal, had been elected, through the efforts of his partisans, president of the Orange Free State. He thereupon (in February 1860) obtained six months' leave of absence and repaired to Bloemfontein, in the hope of peacefully bringing about a union between the two republics. He had no sooner left the Transvaal than the old Lydenburg party, headed by Cornelis Potgieter, landdrost of Lydenburg, protested that the union would be much more beneficial to the Free State than to the people of Lydenburg, and followed this up with the contention that it was illegal for any one to be president of the South African Republic and the Free State at the same time. At the end of the six months Pretorius, after a stormy meeting of the volksraad, apparently in disgust at the whole situation, resigned the presidency of the Transvaal. J. H. Grobelaar, who had been appointed president during the temporary absence of Pretorius, was requested to remain in office. The immediate followers of Pretorius now became extremely incensed at the action of the Lydenburg party, and a mass meeting was held at Potchefstroom (October 1860), where it was resolved that: (*a*) the volksraad no longer enjoyed its confidence; (*b*) that Pretorius should remain president of the South African Republic, and have a year's leave of absence to bring about union with the Free State; (*c*) that Schoeman should act as president during the absence of Pretorius; (*d*) that before the return of Pretorius to resume his duties a new volksraad should be elected.

Internal Dissensions.

If at this stage of their existence the real ambition of the Transvaal Boers was to found a strong and compact republican state, their conduct in opposing a scheme of union with the Orange Free State was foolish to a degree. The events of the year 1860, as well as of all the years that followed down to British annexation in 1877, show that licence rather than liberty, a narrow spirit of faction rather than patriotism, were the dominant instincts of the Boer. Had the fusion of the two little republics which Pretorius sought to bring about, and from which apparently the Free State was not averse, actually been accomplished in 1860, it is more than probable that a republican state on liberal lines, with some prospect of permanence and stability, might have been formed. But a narrow, distrustful, grasping policy on the part of whatever faction might be dominant at the time invariably prevented the state from acquiring stability and security at any stage of its history.

The complications that ensued on the action of the Pretorius party subsequent to his resignation were interminable and complicated. Some of the new party were arraigned for treason and fined; and for several months there were two acting presidents and two rival governments within the Transvaal. At length Commandant Paul Kruger called out the burghers of his district and entered into the strife. Having driven Schoeman and his followers from Pretoria, Kruger invaded Potchefstroom, which, after a skirmish in which three men were killed and seven wounded, fell into his hands. He then pursued Schoeman, who doubled on his opponent and entered Potchefstroom. A temporary peace was no sooner secured than Commandant Jan Viljoen rose in revolt and engaged Kruger's forces. Viljoen's commando, with which Pretorius was in sympathy, was known as the Volksleger, or Army of the People. Kruger's force called itself the Staatsleger or Army of the State. Pretorius in 1863 resigned his Free State presidency and offering himself as mediator (not for the first time) succeeded at length in putting a period to the confused series of intestine quarrels. In January 1864 a conference, which lasted six days, was held between the parties and an agreement was reached. This was followed by a new election for president, and once more Pretorius was called upon to fill that office. Kruger was appointed commandant-general.

Civil strife for a time was at an end, but the injuries inflicted on the state were deep and lasting. The public funds were exhausted; taxes were impossible to collect; and the natives on the borders of the country and in the mountains of the north had thrown off all allegiance to the state. The prestige of the country was practically gone, not only with the world outside, but, what was of still more moment, with her neighbour the Free State, which felt that a federation with the Transvaal, which the Free State once had sought but which it now forswore, was an evil avoided and not an advantage lost.

The Charge of Slavery against the Boers.

A charge frequently laid at the door of the Boers, at that time and since, was that of enslaving the black races. This charge was not without some justification. It is true that laws prohibiting slavery were in existence, but the Boer who periodically took up arms against his own appointed government was not likely to be, nor was he, restrained by laws. Natives were openly transferred from one Boer to another, and the fact that they were described as apprentices by the farmers did not in the least alter the status of the native, who to all intents and purposes became the property of his master. These apprentices, mostly bought from slave traders when little children, formed, however, a very small proportion of the native population, and after some fifteen years' servitude were usually allowed their freedom. Natives enjoying tribal government were not enslaved, but nothing could exceed in ferocity the measures taken to reduce recalcitrant tribes to submission. Education, as need hardly be said, was in the 'sixties at a very low ebb, and nothing approaching the standard of a high school existed. The private tutor was a good deal in demand, but his qualifications were of the slightest. An unsuccessful European carpenter or other mechanic, or even labourer, not infrequently occupied this position. At the various churches such elementary schools as existed were to be found, but they did not profess to teach more than a smattering of the three "R's" and the principles of Christianity.

In 1865 an empty exchequer called for drastic measures, and the volksraad determined to endeavour to meet their liabilities and provide for further contingencies by the issue of notes. Paper money was thus introduced, and in a very short time fell to a considerable discount.

Zoutpansberg Native Rising, 1865-8.

In this same year the farmers of the Zoutpansberg district were driven into laagers by a native rising which they were unable to suppress. Schoemansdal, a village at the foot of the Zoutpansberg, was the most important settlement of the district, and the most advanced outpost in European occupation at that time in South Africa. It was just within the tropics, and was situated in a well-watered and beautiful country. It was used as a base by hunters and traders with the interior, and in its vicinity there gathered a number of settlers of European origin, many of them outcasts from Europe or Cape Colony. They earned the reputation of being the most lawless white inhabitants in the whole of South Africa. When called upon to go to the aid of this settlement, which in 1865–1866 was sore pressed by one of the mountain Bantu tribes known as the Baramapulana, the burghers of the southern Transvaal objected that the white inhabitants of that region were too lawless and reckless a body to merit their assistance. In 1867 Schoemansdal and a considerable portion of the district were abandoned on the advice of Commandant-general Paul Kruger, and Schoemansdal finally was burnt to ashes by a party of natives. It was not until 1869 that peace was patched up, and the settlement arrived at left the mountain tribes in practical independence. Meanwhile the public credit and finances of the Transvaal went from bad to worse. The paper notes already issued had been constituted by law legal tender for all debts, but in 1868 their power of actual purchase was only 30% compared with that of gold, and by 1870 it had fallen as low as 25%. Civil servants, who were paid in this depreciated scrip, suffered considerable distress. The revenue for 1869 was stated as £31,511; the expenditure at £30,836.

The discovery of gold at Tati led President Pretorius in April 1868 to issue a proclamation extending his territories on the west and north so as to embrace the goldfield and all Bechuanaland.

Efforts to obtain a Seaport.

The same proclamation extended Transvaal territory on the east so as to include part of Delagoa Bay. The eastern extension claimed by Pretorius was the sequel to endeavours made shortly before, on the initiative of a Scotsman, to develop trade along the rivers leading to Delagoa Bay. It was also in accord with the desire of the Transvaal Boers to obtain a seaport, a desire which had led them as early as 1860 to treat with the Zulus for the possession of St Lucia Bay. That effort had, however, failed. And now the proclamation of Pretorius was followed by protests on the part of the British high commissioner, Sir Philip Wodehouse, as well as on the part of the consul-general for Portugal in South Africa. The boundary on the east was settled by a treaty with Portugal in 1869, the Boers abandoning their claim to Delagoa Bay; that on the west was dealt with in 1871.

The Sand River Convention of 1852 had not defined the western border of the state, and the discovery of gold at Tati to the north-west, together with the discovery of diamonds on the Vaal in 1867, offered Pretorius every inducement to extend his boundary. Although to-day the great diamond mines are south of the Vaal River, the early discoveries of diamonds were made chiefly on the northern bank of the Vaal, near the site of the town now known as Barkly West.

The Keate Award.

This territory was claimed by the South African Republic, by Barolong and Batlapin Bechuanas, by Koranas, and also by David Arnot, on behalf of the Griqua captain, Nicholas Waterboer. To settle the boundary question an arbitration court was appointed consisting of a Transvaal landdrost, A. A. O'Reilly, on behalf of the South African Republic, and John Campbell on behalf of the other claimants, with Lieutenant-Governor Keate of Natal as referee. The judges disagreed, and the final decision, afterwards known as the Keate award, was given by the referee on the 17th of October 1871. The decision was in favour of Waterboer, who had, on the 25th of August 1870, before the appointment of the arbitration court, offered his territory to Great Britain, and it was understood by all the parties interested that that offer would be accepted. The award, admittedly just on the evidence before Keate, placed, however, outside the territory of the republic the Bloemhof district, in which district Boer farmers were settled, and over which the Pretoria government had for some years exercised jurisdiction. A few days after the publication of the Keate award Sir Henry Barkly, the British high commissioner, issued proclamations taking over Waterboer's territory under the title of Griqualand West (*q.v.*). The eastern boundary of the new territory was made to include the region between the Harts river and the Vaal, in which the diamond diggings were situated, but not the Bloemhof district. To this district Sir Henry Barkly asserted the British rights, but no steps were taken to enforce them and as a matter of fact the Bloemhof district continued to be part of the Transvaal.

The award caused a strong feeling of resentment among the Boers, and led to the resignation of President Pretorius and his executive. The Boers now cast about to find a man who should have the necessary ability, as they said, to negotiate on equal terms with the British authorities should any future dispute arise. With this view they asked Mr (afterwards Sir John) Brand, president of the Free State, to allow them to nominate him for the presidency of the South African Republic. To this President Brand would not consent. He recognized that, even at this early stage of their history, the Transvaal Boers were filled with the wildest ideas as to what steps they would take in the future to counteract the influence of Great Britain. Brand intimated to many of the leading Transvaal Boers that in his opinion they were embarking on a rash and mistaken policy. He urged that their true interests lay in friendship with, not in hostility to, Great Britain and the British. Having failed with Brand, the Boers invited the Rev. Thomas François Burgers, a member of a well-known Cape Colony family and a minister of the Dutch Reformed Church, to allow himself to be nominated. Burgers accepted the offer, and in 1872 was elected president. About this time gold reefs were discovered in the Zoutpansberg district near Marabastad, and a few gold seekers from Europe and Cape Colony began to prospect the northern portions of the Transvaal. The miners and prospectors did not, however, exceed a few hundred for several years.

Burgers becomes President, 1872.

The appointment of Burgers to the presidency in 1872 was a new departure. He was able, active and enlightened, but he was a visionary rather than a man of affairs or sound judgment. Instead of reducing chaos to order and concentrating his attention, as Brand had done in the Free State, on establishing security and promoting industry, he took up, with all its entanglements, the policy of intrigues with native chiefs beyond the border and the dream of indefinite expansion. In 1875 Burgers proceeded to Europe with the project of raising a loan for the construction of a railway to Delagoa Bay. He was empowered by the volksraad to raise £300,000, but with great difficulty he obtained in Holland the sum of £90,000 only, and that at a high rate of interest. With this inadequate sum some railway plant was obtained, and subsequently lay for ten years at Delagoa Bay, the scheme having to be abandoned for want of funds. On his return to the Transvaal in 1876 Burgers found that the conditions of affairs in the state was worse than ever. The acting-president had in his absence been granted leave by the volksraad to carry out various measures opposed to the public welfare; native lands had been indiscriminately allotted to adventurers, and a war with Sikukuni (Secocoeni), a native chief on the eastern borders of the country, was imminent. A commando was called out, which the president himself led. The expedition was an ignominious failure, and many burghers did not hesitate to assign their non-success to the fact that Burgers's views on religious questions were not sound. Burgers then proceeded to levy taxes, which were never paid; to enrol troops, which never marched; and to continue the head of a government which had neither resources, credit nor power of administration. In 1877 the Transvaal one-pound notes were valued at one shilling cash. Add to this condition of things the fact that the Zulus were threatening the Transvaal on its southern border, and the picture of utter collapse which existed in the state is complete.

B. *First Annexation by Great Britain.*—This condition of affairs coincided with the second movement in South Africa for a confederation of its various colonies and states, a movement of which the then colonial secretary, the 4th earl of Carnarvon, was a warm advocate. As to the Transvaal in particular, it was felt by Lord Carnarvon "that the safety and prosperity of the republic would be best assured by its union with the British colonies." Sir Theophilus Shepstone (*q.v.*) was given a commission, dated the 5th of October, 1876, instructing him to visit the Transvaal and empowering him, if it was desired by the inhabitants and in his judgment necessary, to annex the country to the British crown. Sir Theophilus went to Pretoria in January 1877, with an escort of twenty-five mounted police, and entered into conferences with the president and executive as to the state of the country. By this time Burgers was no longer blinded by the foolish optimism of a visionary who had woven finespun theories of what an ideal republic might be. He had lived among the Boers and attempted to lead their government. He had found their idea of liberty to be anarchy, their native policy to be slavery, and their republic to be a sham. His was a bitter awakening, and the bitterness of it found expression in some remarkable words addressed to the volksraad:

"I would rather," said Burgers in March 1877, "be a policeman under a strong government than the president of such a state. It is you—you members of the Raad and the Boers—who have lost the country, who have sold your independence for a drink. You have ill-treated the natives, you have shot them down, you have sold them into slavery, and now you have to pay the penalty. . . . We should delude ourselves by entertaining the hope that matters would mend by-and-by. . . . Do you know what recently happened in Turkey? Because no civilized government was carried on there, the Great Powers interfered and said, 'Thus far and no farther.' And if this is done to an empire, will a little republic be excused when it misbehaves? . . If we want justice, we must be in a position to ask it with unsullied hands. . . ."

After careful investigation Shepstone satisfied himself that annexation was the only possible salvation for the Transvaal. He had gone to Pretoria hoping that the Transvaal volksraad would accept Carnarvon's federation scheme; but the federation proposals were rejected by the raad. Shepstone was willing to find some way other than simple annexation out of the difficulty, but none appeared to present itself. The treasury was empty, the Boers refused to pay their taxes, and there was no power to enforce them. A public debt of £215,000 existed, and government contractors were left unpaid. Sir Theophilus Shepstone, finding that the raad would not adopt any remedial measures, on the 12th of April 1877 issued a proclamation annexing the country. The proclamation stated (among other things): "It is the wish of Her Most Gracious Majesty that it [the state] shall enjoy the fullest legislative privileges compatible with the circumstances of the country and the intelligence of its people." The wisdom of the step taken by Shepstone has been called in question. For many years subsequently the matter was so surrounded with the sophistry of English party politics that it was difficult for Englishmen to form any impartial opinion. The history of the Transvaal is more complete and better understood to-day than it was in 1877, and no one who acquaints himself with the facts will deny that Shepstone acted with care and moderation. The best evidence in favour of the step is to be found in the publicly expressed views of the state's own president, Burgers, already quoted. Moreover, the menace of attack on the Zulu side was a serious one, however able the Boers may have been to meet a foe who fought in the open, and who had been beaten by them in previous wars. Even before annexation had occurred, Shepstone felt the danger so acutely that he sent a message to Cetywayo, the Zulu chief, warning him that British annexation was about to be proclaimed and that invasion of the Transvaal would not be tolerated. To this warning Cetywayo, who, encouraged by the defeat of the Boers at Sikukuni's hands, had already gathered his warriors together, replied: "I thank my father Somtseu [Shepstone] for his message. I am glad that he has sent it, because the Dutch have tired me out, and I intended to fight with them . . . and to drive them over the Vaal. . . ." A still further reason for Shepstone's annexation, given by Sir Bartle Frere, was that Burgers had already sought alliance with European powers, and Shepstone had no reason to doubt that if Great Britain refused to interfere, Germany would intervene. Moreover, apart from the attitude

British Annexation, 1877.

of President Burgers, which cannot be said to have been one of active opposition, a considerable number of the Boers accepted the annexation with complacency. Burgers himself left the Transvaal a disappointed, heart-broken man, and a deathbed statement published some time after his decease throws a lurid light on the intrigues which arose before and after annexation. He shows how, for purely personal ends, Kruger allied himself with the British faction who were agitating for annexation, and to undermine him and endeavour to gain the presidency, urged the Boers to pay no taxes. However this may be, Burgers was crushed; but as a consequence the British government and not Paul Kruger was, for a time at least, master of the Transvaal. In view of his attitude before annexation, it was not surprising that Kruger should be one of the first men to agitate against it afterwards. The work of destruction had gone too far. The plot had miscarried. And so Kruger and Dr Jorissen, by whom he was accompanied, were the first to approach Lord Carnarvon with an appeal for revocation of the proclamation. Lord Carnarvon's reply was that the act of annexation was an irrevocable one. Unfortunately the train of events in England favoured the intrigues of the party who wished the annexation cancelled. In 1878 Lord Carnarvon resigned, and there were other evidences of dissension in the British cabinet.

Kruger, who since the annexation had held a salaried appointment under the British Government, again became one of a deputation to England. His colleague was Piet Joubert. They laid their case before Sir Michael Hicks Beach (who had succeeded Lord Carnarvon) but met with no success. Sir Michael, however, in a despatch dated September the 16th 1878, reiterated the intention of the British cabinet to grant the state "to the utmost practicable extent, its individuality and powers of self-government under the sovereignty of the queen." On the occasion of Kruger's second mission to endeavour to get the annexation revoked Sir T. Shepstone determined to dispense with his further services as a government servant, and terminated the engagement. In the beginning of 1879 Shepstone was recalled and Colonel Owen Lanyon, who had served in Bechuanaland and was then administrator of Griqualand West, was appointed administrator in the Transvaal. In the meantime, the Zulu forces which threatened the Transvaal had been turned against the British, and the disaster of Isandhlwana occurred. Rumours of British defeat soon reached the Transvaal, and encouraged the disaffected party to become bolder in their agitation against British rule. Thus Sir Bartle Frere wrote at the time: "All accounts from Pretoria represent that the great body of the Boer population is still under the belief that the Zulus are more than a match for us, that our difficulties are more than we can surmount, and that the present is the favourable opportunity for demanding their independence." In April Frere visited Pretoria and conferred with the Boers. He assured them that they might look forward to complete self-government under the Crown, and at the same time urged them to sink political differences and join hands with the British against their common enemy, the Zulus. The Boers, however, continued to agitate for complete independence, and, with the honourable exception of Piet Uys, a gallant Boer leader, and a small band of followers, who assisted Colonel Evelyn Wood at Hlobani, the Boers held entirely aloof from the conflict with the Zulus, a campaign which cost Great Britain many lives and £5,000,000 before the Zulu power was finally broken. In June Sir Garnet Wolseley went to South Africa as commander of the forces against the Zulus, and as high commissioner "for a time," in the place of Sir Bartle Frere, of the Transvaal and Natal. Meantime Frere's proposals to fulfil the promises made to grant the Boers a liberal constitution were shelved. After the "settlement" of the Zulu question, Sir Garnet Wolseley proceeded to Pretoria and immediately organized an expedition against Sikukuni, who throughout the Zulu campaign had been acting under the advice of Cetywayo. Sikukuni's stronghold was captured and his forces disbanded.

Agitation for Independence.

Sir Garnet Wolseley now assured the Boers at a public gathering that so long as the sun shone the British flag would fly at Pretoria. In May 1880 he returned to England, having established in the Transvaal a legislative council with powers so limited as to convince many of the Boers that there was no intention of fulfilling Shepstone's promises. Meanwhile events in Great Britain had once more taken a turn which gave encouragement to the disaffected Boers. Already in November 1879 Gladstone had conducted his Midlothian campaign. In one speech, referring to Cyprus and the Transvaal, he said: "If those acquisitions were as valuable as they are valueless, I would repudiate them, because they were obtained by means dishonourable to the character of our country." And in another speech he said that the British had insanely placed themselves in the strange predicament of the free subjects of a monarchy going to coerce the free subjects of a republic. Expressions such as these were translated into Dutch and distributed among the Boers, and they exercised a good deal of influence in fanning the agitation already going on in the Transvaal. So keenly were the Midlothian speeches appreciated by the Boers that the Boer committee wrote a letter of thanks to Gladstone, and expressed the hope that should a change in the government of Great Britain occur, "the injustice done to the Transvaal might find redress." In April 1880, this change in the British Government did occur. Gladstone became prime minister, and shortly afterwards Frere was recalled. Could events be more auspicious for the party seeking retrocession? On being directly appealed to by Kruger and Joubert, Gladstone however replied that the liberty which they sought might be "most easily and promptly conceded to the Transvaal as a member of a South African Confederation." This was not at all what was wanted, and the agitation continued. Meanwhile in the Transvaal, concurrently with the change of prime minister and high commissioner, the administrator, Colonel Lanyon, began vigorously to enforce taxation among the Boers. Men who would not pay taxes to their own appointed governments, and who were daily expecting to be allowed to return to that condition of anarchy which they had come to regard as the normal order of things, were not likely to respond willingly to the tax-gatherer's demands. That many of them refused payment in the circumstances which existed was natural.

Effect of Mr Gladstone's Speeches in England.

In November matters were brought to a head by the wagons of a farmer named Bezuidenhout being seized in respect of the non-payment of taxes, and promptly retaken from the sheriff by a party of Boers. Lanyon began to recognize that the position was becoming grave, and telegraphed to Sir George Colley, the high commissioner of South-East Africa, for military aid. This, however, was not immediately available, and on the 13th of December the Boers in public meeting at Paardekraal resolved once more to proclaim the South African Republic, and in the meantime to appoint a triumvirate, consisting of Kruger, Pretorius and Joubert, as a provisional government. Within three days of the Paardekraal meeting a letter was sent to the administrator demanding the keys of the government offices. Formal proclamation of the republic was made on the 16th of December (Dingaan's Day) at Heidelberg. Hostilities forthwith began. Meanwhile pressure was put on the British prime minister to carry out the policy he had avowed while out of office. But it was not until Great Britain was suffering from the humiliation of defeat that he was convinced that the time for granting that retrocession had arrived. The first shots fired were outside Potchefstroom, which was then occupied by a small British garrison (see POTCHEFSTROOM). On the 20th of December some 240 men under Colonel Anstruther, chiefly belonging to the 94th Regiment, while marching from Lydenburg to Pretoria, were surprised at Bronkhorst Spruit, and cut up by the Boer forces. Half the men were killed and wounded; the other half including some officers, were taken prisoners. Captain Elliot, one of the prisoners, who had been released on parole, was shot dead by Boers while crossing the Vaal, and Captain Lambert, another paroled prisoner who accompanied Elliot, was also shot,

Outbreak of War, 1880.

but escaped. Pretoria, Rustenberg, Lydenburg, and other smaller towns had been placed in a position of defence under the directions of Colonel Bellairs, who remained in command at Pretoria, the garrison consisting of a small number of troops and the loyal inhabitants. Sir George Colley, with about 1400 men, marched towards the Transvaal frontier, but before reaching it he found, on the 24th of January 1881, that the Boers had already invaded Natal and occupied Laing's Nek. He pitched his camp at Ingogo. Having been defeated at Laing's Nek, and suffered considerable loss in an engagement near Ingogo, Colley took a force to the top of Majuba, a mountain overlooking the Boer camp and the nek. He went up during the night, and in the morning was attacked and overwhelmed by the Boers (Feb. 27). Of the 554 men who constituted the British force on Majuba, 92 were killed and 134 wounded, Sir George Colley himself being amongst those who were slain.

Majuba Hill, 1881.

Ten days previous to the disaster at Majuba Sir Evelyn Wood had arrived at Newcastle with reinforcements. On Colley's death he assumed command. Negotiations had been opened with the Boers before the attack on Majuba and the British cabinet refused to allow that disaster to influence their action. On the 6th of March a truce was concluded and on the 21st terms of peace were arranged between the Boer triumvirate and Sir Evelyn Wood. The most important of these terms were that the Transvaal should have complete internal self-government under British suzerainty and that a British resident should be stationed at Pretoria. Another article reserved to her majesty "the control of the external relations of the said state, including the conclusion of treaties and the conduct of diplomatic intercourse with foreign powers," and the right to march troops through the Transvaal. The boundaries of the state were defined, and to them the Transvaal was strictly to adhere. These terms practically conceded all that the Boers demanded, and were never regarded as anything else than surrender either by the Boers or the loyalists in South Africa. The agreement had hardly been concluded when Sir Frederick Roberts arrived at the Cape with 10,000 troops, and after spending forty-eight hours there returned to England.

In the meantime, while the British general was making a treaty under the instructions of British ministers on the frontier, the beleaguered garrisons of Pretoria, Potchefstroom, and other smaller towns were gallantly holding their own. The news of the surrender reached Pretoria through Boer sources, and when first received there was laughed at by the garrison and inhabitants as a Boer joke. When the bitter truth was at length realized, the British flag was dragged through the dust of Pretoria streets by outraged Englishmen. Presently there assembled in Pretoria a commission to elaborate the terms of peace. On the one side were the Boer triumvirate, on the other Sir Evelyn Wood, Sir Hercules Robinson (Frere's successor in the high commissionership), and Sir J. H. de Villiers, chief justice of Cape Colony, while President Brand of the Orange Free State gave the commission the benefit of his advice. The terms agreed upon were drawn up in the form of a convention and signed (Aug. 3). The preamble to the Pretoria Convention of 1881 contained in brief but explicit terms the grant of self-government to the Boers, subject to British suzerainty. In later years, when the Boers desired to regard the whole of this convention (and not merely the articles) as cancelled by the London Convention of 1884, and with it the suzerainty, which was only mentioned in the preamble, Mr Chamberlain, a member of the cabinet of 1880–1885, pointed out that if the preamble to this instrument were considered cancelled, so also would be the grant of self-government.

Pretoria Convention.

The government of the state was handed over to the triumvirate on the 8th of August and was continued in their name until May 1883, when Kruger was elected president.

C. *From the Retrocession to 1899.*—The retrocession of the Transvaal was a terrible blow to the loyalists. The Boers, on the other hand, found themselves in better plight than they had ever been before. Their native foes had been crushed by British forces; their liabilities were consolidated into a debt to Great Britain, to be repaid at convenience and leisure—as a matter of fact, not even interest was paid for some time. If ever a small state was well treated by a large one, the Transvaal was so in the retrocession of 1881. Unfortunately, this magnanimity was forthcoming after defeat It appeared as though a virtue had been made of a necessity, and the Boers never regarded it in any other light.

The new volksraad had scarcely been returned and the Pretoria Convention ratified (Oct. 25) before a system of government concessions to private individuals was started. These concessions, in so far as they prejudiced the commerce and general interests of the inhabitants, consisted chiefly in the granting of monopolies. Among the first monopolies which were granted in 1882 was one for the manufacture of spirituous liquor. The system continued steadily down to 1899, by which time railways, dynamite, spirits, iron, sugar, wool, bricks, jam, paper and a number of other things were all of them articles of monopoly. In 1882 also began that alteration of the franchise law which subsequently developed into positive exclusion of practically all save the original Boer burghers of the country from the franchise. In 1881, on the retrocession, full franchise rights could be obtained after two years' residence; in 1882 the period of residence was increased to five years. Meanwhile the land-hunger of the Boers became stimulated rather than checked by the regaining of the independence of their country. On the western border, where the natives were of less warlike character than those on their southern and northern frontiers, intrigues were already going on with petty tribal chiefs, and the Boers drove out a portion of the Barolongs from their lands, setting up the so-called republics of Stellaland and Goshen. This act called forth a protest from the 15th Lord Derby (now secretary of state for the colonics), stating that he could not recognize the right of Boer freebooters to set up governments of their own on the Transvaal borders. This protest had no effect upon the freebooters, who issued one proclamation after another, until in November 1883 they united the two new republics under the title of the "United States of Stellaland." Simultaneously with this "irresponsible" movement for expansion, President Kruger proceeded to London to interview Lord Derby and endeavour to induce him to dispense with the suzerainty, and to withdraw other clauses in the Pretoria Convention on foreign relations and natives, which were objectionable from the Boer point of view. Moreover, Kruger requested that the term "South African Republic" should be substituted for Transvaal State.

The New Régime.

The result was the London Convention of the 27th of February 1884. In this document a fresh set of articles was substituted for those of the Pretoria Convention of 1881. In the articles of the new convention the boundaries were once more defined, concessions being made to the Transvaal on the Bechuanaland frontier, and to them the republic was bound to "strictly adhere." In what followed it must always be remembered that Lord Derby began by emphatically rejecting the first Boer draft of a treaty on the ground that no treaty was possible except between equal sovereign states. Moreover, it is undeniable that Lord Derby acted as though he was anxious to appear to be giving the Boers what they wanted. He would not formally abolish the suzerainty, but he was willing not to mention it; and though, in substituting new articles for those of the Pretoria Convention he left the preamble untouched, he avoided anything which could commit the Boer delegates to a formal recognition of that fact. On the other hand, he was most indignant when in the House of Lords he was accused by Lord Cairns of impairing British interests and relinquishing the queen's suzerainty. He declared that he had preserved the thing in its substance, if he had not actually used the word; and this view of the matter was always officially maintained in the colonial office (which, significantly enough,

London Convention, 1884.

dealt with Transvaal affairs) whatever the political party in power. Unfortunately, the timid way in which it was done made as ineffaceable an impression on Kruger even as the surrender after Majuba. Article 4 stated:

"The South African Republic will conclude no treaty or engagement with any state or nation, other than the Orange Free State, nor with any native tribe to the eastward or westward of the Republic, until the same has been approved by her Majesty the Queen."

The other article to which the greatest interest was subsequently attached was art. 14:

"All persons, other than natives, conforming themselves to the laws of the South African Republic (*a*) will have full liberty, with their families, to enter, travel, or reside in any part of the South African Republic; (*b*) they will be entitled to hire or possess houses, manufactories, warehouses, shops and premises; (*c*) they may carry on their commerce either in person or by any agents whom they may think fit to employ; (*d*) they will not be subject, in respect of their persons or property, or in respect of their commerce or industry, to any taxes, whether general or local, other than those which are or may be imposed upon citizens of the said Republic."

Territorial Expansion Efforts.

Notwithstanding the precise fixing of the boundaries of the republic by the London Convention, President Kruger endeavoured to maintain the Boer hold on Goshen and Stellaland, but the British government on this point proved firm, and an expedition set out in 1884 under Sir Charles Warren, broke up the freebooters' two states, and occupied the country without a shot being fired (see BECHUANALAND). The expedition cost Great Britain a million and a half, but the attempt at farther extension westwards was foiled, and a little later treaties with Lobenguela and the grant to Cecil Rhodes and his co-directors of a charter for the British South Africa Company put a check on designs the Boers held to expand northward (see RHODESIA). On the eastern border a similar policy of expansion was followed by the Boers, and in this instance with more success. Following up the downfall of the Zulu power after the British conquest in 1879, several parties of Boers began intriguing with the petty chiefs, and in May 1884, in the presence of 10,000 Zulus, they proclaimed Dinizulu, the son of Cetywayo, to be king of Zululand (see ZULULAND). As a "reward" for their services to the Zulus, the Boers then took over from them a tract of country in which they established a "New Republic." In 1886 the "New Republic" with limits considerably narrowed, was recognised by Great Britain, and the territory became incorporated with the Transvaal in 1888. Their eastern boundary, in the teeth of the spirit of the conventions, and with but scant observance of the letter, was by this means considerably extended. A similar policy eventually brought Swaziland almost entirely under their dominion (see SWAZILAND). At the same time President Kruger revived the project of obtaining a seaport for the state, one of the objects of Boer ambitions since 1860 (vide *supra*). Kruger endeavoured to acquire Kosi Bay, to the north of Zululand and only 50 m. east of the Swazi frontier. Meanwhile, events occurring within the state augured ill for the future of the country. In 1884 a concession to a number of Hollander and German capitalists of all rights to make railways led to the formation of the Netherlands Railway Company. This company, which was not actually floated till 1887, was destined to exercise a disastrous influence upon the fortunes of the state.

Economic Developments: Gold Industry.

Gold digging had hitherto enjoyed in the Transvaal but a precarious existence. In 1883 the discovery of Moodie's Reef near the Kaap Valley led to a considerable influx of diggers and prospectors from the colonies and Europe, and by 1884 the Sheba Mine had been opened up, and Barberton, with a population of 5000 inhabitants, sprung into existence. In 1886 the Rand goldfields, which had just been discovered, were proclaimed and Johannesburg was founded. From that time the gold industry made steady progress until the Rand gold mines proved the richest and most productive goldfield in the world. As the industry prospered, so did the European population increase. The revenue of the state went up by leaps and bounds. At the end of 1886 Johannesburg consisted of a few stores and some few thousand inhabitants. In October 1896 the sanitary board census estimated the population as 107,078, of whom 50,907 were Europeans. The wealth which was pouring into the Boer state coffers exceeded the wildest dreams of President Kruger and his followers. Land went up in value, and farms, many of them at comparatively remote distances from the goldfields, were sold at enormously enhanced prices. In fact, so attractive did this sale of land become to the Boers that they eventually parted with a third of the whole land area of the country to Uitlander purchasers. Yet in spite of the wealth which the industry of the Uitlanders was creating, a policy of rigid political exclusion and restriction was adopted towards them.

Relations with the rest of South Africa.

An attempt was made in 1888, after the conference held between Cape Colony, the Orange Free State and Natal, to induce the Transvaal to enter a customs union. Kruger would have none of it, although by so doing he could have obtained permission for a settlement at and railway to Kosi Bay. A convention to this effect was signed in August 1890, the Transvaal being allowed three years in which to take advantage of its provisions. Kruger's design at this time was to bring the whole of the external trade of the state, which was growing yearly as the gold industry developed, through Delagoa Bay and over the Netherlands railway. His hostility towards Great Britain and even Cape Colony led him to adopt a commercial policy both narrow and prejudicial to the interests of the gold industry. In the appointment of F. W. Reitz as president of the Orange Free State (January 1889) on the death of Sir John Brand, Kruger recognized a new opportunity of endeavouring to cajole the Free State. Brand had arranged, in the teeth of the strongest protests from Kruger, that the Cape railway should extend to Bloemfontein and subsequently to the Vaal river. Kruger now endeavoured to control the railway policy of the Free State, and induced that republic to agree to a treaty whereby each state bound itself to help the other whenever the independence of either should be threatened or assailed, unless the cause of quarrel was, in the eyes of the state called in to assist, an unjust one (see ORANGE FREE STATE).

Oligarchical Restrictions.

In 1890 a feeling of considerable irritation had grown up among the Uitlanders at the various monopolies, but particularly at the dynamite monopoly, which pressed solely and with peculiar severity upon gold miners. Requests for consideration in the matter of the franchise, and also for a more liberal commercial policy in the matter of railways, dynamite and customs dues, began to be made. In response Kruger enacted that the period of qualification for the full franchise should now be raised to ten years instead of five. He at the same time instituted what was called a second chamber, the franchise qualifications for which were easier, but which was not endowed with any real power. During this year Kruger visited Johannesburg, and what was known as "the flag incident" occurred. He had by this time rendered himself somewhat unpopular, and in the evening the Transvaal flag, which flew over the landdrost's house, was pulled down. This incensed Kruger so much that for many years he continued to quote it as a reason why no consideration could be granted to the Uitlanders.

Uitlander Grievances.

By 1892 the Uitlanders began to feel that if they were to obtain any redress for their grievances combined constitutional action was called for, and the first reform movement began. The Transvaal National Union was formed. This consisted at the outset chiefly of mercantile and professional men and artisans. The mining men, especially the heads of the larger houses, did not care at this juncture to run the risk of political agitation. The Hon. J. Tudhope, an ex-minister in the Cape government, was elected chairman of the union. The objects of this body were avowed from the outset. They desired equal rights for all citizens, the abolition of monopolies and abuses, together with the maintenance of the state's independence. In the furthering of this policy Tudhope was supported by Charles Leonard and his brother

James Leonard, at one time attorney-general of Cape Colony. Both the Leonards, as well as many of their followers, were South Africans by birth. They, in common with the great bulk of the Uitlanders, recognized that the state had every right to have its independence respected. But they asserted that a narrow and retrogressive policy, such as Kruger was following, was the very thing to endanger that independence. The soundness of these views and the legitimacy of Uitlander aspirations were recognized by a few Boer officials at Pretoria. Some prominent burghers even spoke at Uitlander meetings in favour of the Uitlander requests. At a later date, Chief Justice Kotze, when on circuit, warned the Boers that in its retrogressive action the government was undermining the *grondwet* or constitution of the state. It soon became evident that one course, and one only, lay open to President Kruger if he desired to avert a catastrophe. It was to meet in a friendly spirit those men who had by their industry converted a poor pastoral country into a rich industrial one, who represented more than half the inhabitants, who paid more than three-fourths of the revenue, and who were anxious to join him as citizens, with the rights of citizenship. He chose a course diametrically opposite. In an interview accorded to seven delegates from the National Union, in 1892, he told Charles Leonard to "go back and tell your people that I shall never give them anything. I shall never change my policy. And now let the storm burst." In 1894 there occurred an incident which not only incensed the Uitlanders to fury, but called for British intervention. A number of British subjects resident in the Transvaal, in spite of their having no political status, were commandeered to suppress a native rising. This led to a protest, and eventually a visit to Pretoria, from Sir Henry Loch the high commissioner. In the negotiations which followed, President Kruger at length agreed to extend "most favoured nation" privileges to British subjects in reference to compulsory military service, and five British subjects who had been sent as prisoners to the front were released. This result was not, however, achieved before President Kruger had done his utmost to induce Sir Henry Loch to promise some revision in favour of the Transvaal of the London Convention. Following this incident came a further alteration in the franchise law, making the franchise practically impossible to obtain. At a banquet given in honour of the German emperor's birthday in Pretoria in January 1895, Kruger referred in glowing terms to the friendship of Germany for the Transvaal, which in the future was to be more firmly established than ever. This speech was public evidence of what was known to be going on behind the scenes. The German consul at Pretoria at this juncture as a volatile, sanguine man, with visionary ideas of the important part Germany was to play in the future as the patron and ally of the South African Republic, and of the extent to which the Bismarckian policy might go in abetting an anti-British campaign. Whether he deceived himself or not, he led President Kruger and the Boers to believe that Germany was prepared to go to almost any length in support of the Transvaal if any opportunity occurred. His influence was an undoubted factor in the Kruger policy of that time.

Commandeering Incident, 1894.

German Flirtation.

The Delagoa Bay railway being at length completed to Pretoria and Johannesburg, Kruger determined to take steps to bring the Rand traffic over it. The Netherlands railway began by putting a prohibitive tariff on goods from the Vaal river. Not to be coerced in this manner, the Rand merchants proceeded to bring their goods on from the Vaal by wagon. Kruger then closed the drifts (or fords) on the river by which the wagons crossed. He only reopened them after the receipt of what was tantamount to an ultimatum on the subject from Great Britain.

Drifts Incident.

In May 1895, on the urgent representations of Sir Henry Loch, the British government annexed Tongaland, including Kosi Bay, thus making the British and Portuguese boundaries conterminous on the coast of south-east Africa. In the previous month certain native territories between Tongaland and Swaziland had been annexed by Great Britain. The Boers, who had failed to fulfil the conditions under which they might have secured Kosi Bay, nevertheless resented this action, which took away from them all chance of obtaining a seaport. Kruger telegraphed that "this annexation cannot be regarded by this government otherwise than as directed against this republic. They must therefore regard it as an unfriendly act, against which they hereby protest." The protest was unheeded, the British government having realized the international complications that might ensue had the Transvaal a port of its own.

Boer Road to the Sea Blocked.

At this time the Uitlanders formed a majority of the population, owned half the land and nine-tenths of the property, and they were at least entitled to a hearing. When in August 1895 they forwarded one of their many petitions praying for redress of their grievances and an extension of the franchise, their petition, with over 35,000 signatures, was rejected with jeers and insult. One member of the Raad, during a debate in the chamber, called upon the Uitlanders to "come on and fight" for their rights if they wanted them. The words were but the utterance of an individual Raad member, but they were only a shade less offensive than those used by Kruger in 1892, and they too accurately describe the attitude of the Boer executive. In September a meeting of the chambers of mines and commerce was held at Johannesburg, and a letter on various matters of the greatest importance to the mining industry was addressed to the Boer executive. It was never vouchsafed an answer. What the next step should be was freely discussed. Some urged an appeal to the Imperial government; but others, especially men of colonial birth and experience, objected that they would be leaning on a broken reed. That men who had still the memory of Majuba in their hearts should have felt misgiving is not to be wondered at. At this juncture (October 1895) came overtures to the leading Uitlanders from Cecil Rhodes, then prime minister of Cape Colony, and from Dr Jameson, leading to the Jameson Raid. To one or two men this scheme, subsequently known as the Jameson Plan, had been revealed in the previous June, but to the majority even of the small group of leaders it was not known till October or November 1895. The proposition came in a tempting hour. Rhodes and Jameson, after considerable deliberation, came to the conclusion that they might advantageously intervene between Kruger and the Uitlanders. They induced Alfred Beit, who was an old personal friend of Rhodes, and also largely interested in the Rand gold mines, to lend his co-operation. They then submitted their scheme to some of the Uitlander leaders. Between them it was arranged that Jameson should gather a force of 800 men on the Transvaal border; that the Uitlanders should continue their agitation; and that, should no satisfactory concession be obtained from Kruger, a combined movement of armed forces should be made against the government. The arsenal at Pretoria was to be seized; the Uitlanders in Johannesburg were to rise and hold the town. Jameson was to make a rapid march to Johannesburg. Meanwhile, in order to give Kruger a final chance of making concessions with a good grace, and for the purpose of stating the Uitlander case to the world, Charles Leonard, as chairman of the National Union, issued a historic manifesto, which concluded as follows:—

Uitlander Reform Movement.

The "Jameson Plan."

We have now only two questions to consider: (*a*) What do we want? (*b*) How shall we get it? I have stated plainly what our grievances are, and I shall answer with equal directness the question, What do we want? We want: (1) the establishment of this republic as a true republic; (2) a *grondwet* or constitution which shall be framed by competent persons selected by representatives of the whole people and framed on lines laid down by them—a constitution which shall be safeguarded against hasty alteration; (3) an equitable franchise law, and fair representation; (4) equality of the Dutch and English languages; (5) responsibility to the heads of the great departments of the legislature; (6) removal of religious disabilities; (7) independence of the courts of justice, with adequate and secured remuneration of the judges; (8) liberal and comprehensive education;

(9) efficient civil service, with adequate provision for pay and pension; (10) free trade in South African products. That is what we want. There now remains the question which is to be put before you at the meeting of the 6th of January, viz. How shall we get it? To this question I shall expect from you an answer in plain terms according to your deliberate judgment.

The Jameson conspiracy fared no worse and no better than the great majority of conspiracies in history. It failed in its immediate object. Jameson did not obtain more than 500 men. Johannesburg had the greatest difficulty in smuggling in and distributing the rifles with which the insurgents were to be armed. The scheme to seize the Pretoria fort had to be abandoned, as at the time fixed Pretoria was thronged with Boers. Finally, to make confusion worse confounded, Jameson, becoming impatient of delay, in spite of receiving direct messages from the leaders at Johannesburg telling him on no account to move, marched into the Transvaal.

The policy of delay in the execution of the plot which the Uitlander leaders found themselves compelled to adopt was determined by a variety of causes. Apart from the difficulty of obtaining arms, a serious question arose at the eleventh hour which filled some of the Uitlanders with mistrust. The reform leaders in the Transvaal, down to and including the Johannesburg rising, had always recognized as a cardinal principle the maintenance of the independence of the state. From Cape Town it was now hinted that the movement in which Jameson was to co-operate should, in Rhodes's view, be carried out under the British flag. A meeting of Uitlander leaders was hastily summoned on the 25th of December. Two messengers were that night despatched to interview Rhodes, who then gave the assurance that the flag question might be left to a plebiscite of the inhabitants of the Transvaal[1] (see Blue-book, 1897, 165, p. 21). It was determined nevertheless to postpone action; however, on the 29th of December, Jameson started, and the news of his having done so reached Johannesburg from outside sources. A number of leading citizens were at once formed into a reform committee. In the absence of Charles Leonard, who had been sent as one of the delegates to Cape Town to interview Rhodes, Lionel Phillips, a partner in Messrs Eckstein & Co., the largest mining firm on the Rand, was elected chairman. Phillips had been for three years in succession chairman of the chamber of mines, and he had persistently for several years tried to induce Kruger to take a reasonable view of the requirements of the industry. Under the supervision of the reform committee, such arms as had been smuggled in were distributed, and Colonel Frank Rhodes was given charge of the armed men. A large body of police was enrolled, and order was maintained throughout the town. On the 2nd of January 1896 Jameson, who found himself at Doornkop in a position surrounded by Boers, surrendered. Jameson and his men were conveyed to Pretoria as prisoners, and subsequently handed over to the high commissioner (Sir Hercules Robinson, who had succeeded Sir Henry Loch in June 1895).

Collapse of Jameson Raid.

Significant of the attitude of Germany—whose "flirtation" with the Transvaal has been noted—was an open telegram sent by the emperor William II. the day after the surrender of Jameson congratulating Kruger that "without appealing to the help of friendly powers" he had repelled the raiders. The British government rejoined by commissioning a flying squadron and by calling attention to the London Convention, reserving the supervision of the foreign relations of the Transvaal to Great Britain. In Johannesburg meanwhile the Kruger government regained control. The whole of the reform committee (with the exception of a few who fled the country) were arrested on a charge of high treason and imprisoned in Pretoria. In April, at the trial, the four leaders—Lionel Phillips, Frank Rhodes, J. H. Hammond and George Farrar, who in conjunction with Charles Leonard had made the arrangements with Jameson—were sentenced to death, the sentence being after some months' imprisonment commuted to a fine of £25,000 each. The rest of the committee were each sentenced to two years' imprisonment, £2000 fine or another year's imprisonment, and three years' banishment. This sentence, after a month's incarceration, was also commuted. The fine was exacted, and the prisoners, with the exception of Woolls Sampson and W. D. (Karri) Davies, were liberated on undertaking to abstain from politics for three years in lieu of banishment. Messrs Sampson and Davies, refusing to appeal to the executive for a reconsideration of their sentence, were retained for over a year.

The Kaiser's Telegram.

Sir Hercules Robinson was unfortunately in feeble health at the time, and having reached Pretoria on the 4th of January, he had to conduct negotiations under great physical disadvantage. He had no sooner learnt of the raid in Cape Town than he issued a proclamation through Sir Jacobus de Wet, the British resident at Pretoria, warning all British subjects in Johannesburg or elsewhere from aiding and abetting Jameson. This was freely distributed among the public of Johannesburg. While in Pretoria the high commissioner in the first instance addressed himself to inducing Johannesburg to lay down its arms. He telegraphed to the reform committee that Kruger had insisted "that Johannesburg must lay down arms unconditionally as a precedent to any discussions and consideration of grievances." On the following day, the 7th of January, Sir Hercules telegraphed again through the British agent, who was then at Johannesburg, saying: "That if the Uitlanders do not comply with my request they will forfeit all claims to sympathy from Her Majesty's government and from British subjects throughout the world, as the lives of Jameson and the prisoners are now practically in their hands." The two thousand odd rifles which had been distributed among the Uitlanders were then given up. With regard to the inducements to this step urged upon the reform committee by the high commissioner, it is only necessary to say with reference to the first that the grievances never were considered, and with reference to the second it subsequently appeared that one of the conditions of the surrender of Jameson's force at Doornkop was that the lives of the men should be spared. It was after the Johannesburg disarmament that Kruger had sixty-four members of the reform committee arrested, announcing at the same time that his motto would be "Forget and forgive." Sir Hercules Robinson, in response to a message from Mr Chamberlain, who had been secretary of state for the colonies since July 1895, urging him to use firm language in reference to reasonable concessions, replied that he considered the moment inopportune, and on the 15th of January he left for Cape Town. In 1897 he was succeeded in the high commissionership by Sir Alfred Milner.

The Surrender of Johannesburg.

In the period which intervened between the Jameson raid and the outbreak of the war in October 1899 President Kruger's administration continued to be what it had been; that is to say, it was not merely bad, but it got progressively worse. His conduct immediately after Johannesburg had given up its arms, and while the reform committee were in prison, was distinctly disingenuous. Instead of discussing grievances, as before the Johannesburg disarmament he had led the high commissioner to believe was his intention, he proceeded to request the withdrawal of the London Convention, because, among other things, "it is injurious to dignity of independent republic." When Kruger found that no concession was to be wrung from the British government, he proceeded, instead of considering grievances, to add considerably to their number. The Aliens Expulsion

After the Raid.

[1] Jameson, speaking at Durban on the 9th of August 1910, declared that the raid was not racial in the sense usually understood, but an effort towards federation. During the raid he carried a letter containing the names of the proposed new executive, and had the raid succeeded it was proposed to make General Lukas Meyer (d. 1902) president. Jameson subsequently explained that Rhodes and he in designating "an eminent Dutchman" as president of "the new provincial republic" had had no communication with Meyer on the subject. Neither he (Jameson) nor Rhodes had any knowledge of a proposal, to which General Botha had publicly referred, that Charles Leonard should be president. (See the *Cape Times Weekly Edition*, Sept. 7, 1910, p. 15.)

and Aliens Immigration Laws, as well as the new Press Law, were passed in the latter part of 1896.

In 1897 a decision of Chief Justice Kotze was overruled by an act of the volksraad. This led to a strong protest from the judges of the high court, and eventually led to the dismissal of the chief justice, who had held that office for over twenty years, and during the whole of that time had been a loyal and patriotic friend to his country. An industrial commission appointed during this year by President Kruger fared no better than the high court had done. The commission was deputed to inquire into and report on certain of the grievances adversely affecting the gold industry. Its constitution for this purpose was anomalous, as it consisted almost entirely of Transvaal officials whose knowledge of the requirements of the industry was scanty. In spite of this fact, however, the commission reported in favour of reform in various directions. They urged, among other things, due enforcement of the liquor law, more police protection, the abolition of the dynamite concession, and that foodstuffs should be duty free. These recommendations made by President Kruger's own nominees were practically ignored. In 1898, to strengthen his relations with foreign powers, Kruger sent the state secretary, Dr Leyds,[1] to Europe as minister plenipotentiary, his place on the Transvaal executive being taken by Mr Reitz, the ex-president of the Free State. At home Kruger continued as obdurate as ever. In January 1899 Mr Chamberlain pointed out in a despatch to President Kruger that the dynamite monopoly constituted a breach of the London Convention. To help the Transvaal government out of its difficulty, and to make one more effort towards conciliation, the financial houses of Johannesburg offered to lend the Transvaal government £600,000 wherewith to buy out the dynamite company, and so terminate the scandal and bring some relief to the industry. The offer was not accepted. Meantime Sir Alfred Milner had also endeavoured to induce the Transvaal government to grant the necessary reforms, but his efforts were equally unavailing (see MILNER, VISCOUNT). In March the Uitlanders, hopeless of ever obtaining redress from President Kruger, weary of sending petitions to the Raad only to be jeered at, determined to invoke intervention if nothing else could avail, and forwarded a petition to Queen Victoria. This petition, the outcome of the second Uitlander movement for reform, was signed by 21,000 British subjects, and stated the Uitlander position at considerable length. The following extract conveys its general tenor:—

Petition to the Queen.

> The condition of your Majesty's subjects in this state has become well-nigh intolerable. The acknowledged and admitted grievances, of which your Majesty's subjects complained prior to 1895, not only are not redressed, but exist to-day in an aggravated form. They are still deprived of all political rights, they are denied any voice in the government of the country, they are taxed far above the requirements of the country, the revenue of which is misapplied and devoted to objects which keep alive a continuous and well-founded feeling of irritation, without in any way advancing the general interest of the state. Maladministration and peculation of public moneys go hand in hand, without any vigorous measures being adopted to put a stop to the scandal. The education of Uitlander children is made subject to impossible conditions. The police afford no adequate protection to the lives and property of the inhabitants of Johannesburg; they are rather a source of danger to the peace and safety of the Uitlander population.

In response to this appeal, Mr Chamberlain, in a despatch dated the 10th of May, proposed a conference at Pretoria. Six days before Sir Alfred Milner had telegraphed to London a summary of the situation, comparing the position of the Uitlanders to that of helots and declaring the case for intervention to be overwhelming. Neither of these despatches was made public at the time. But on the very day Mr Chamberlain wrote his despatch the friends of the Transvaal government in Cape Colony and the Orange Free State invited Sir Alfred Milner to meet President Kruger at Bloemfontein, hoping to be able to exert pressure on both parties and to arrange a settlement as favourable as possible to the Transvaal. The conference opened on the 31st of May and closed on the 5th of June. It no sooner opened than it was evident that Kruger had come to obtain, not to grant, concessions. He offered, it is true, a seven years' franchise law in place of the five years' franchise which Sir Alfred Milner asked for. But apart from the relief suggested being entirely inadequate, it was only to be given on certain conditions, one of which was that all future disputes which might arise between the Transvaal and the Imperial government should be referred to a court of arbitration, of which the president should be a foreigner. No arrangement was possible on such terms. Meanwhile feeling was running high at Johannesburg and throughout South Africa. Meetings were held in all the large towns, at which resolutions were passed declaring that no solution of the Transvaal question would be acceptable which did not provide for equal political rights for all white men. Sir Alfred Milner urged the home government strongly to insist upon a minimum of reform, and primarily the five years' franchise; and Mr Chamberlain, backed by the cabinet, adopted the policy of the high commissioner. (A. P. H.; F. R. C.)

Bloemfontein Conference.

D. *The Crisis of 1899.*—A state of extreme diplomatic tension lasted all the summer. The British public, in whom there had always been the latent desire to retrieve the surrender to the Boers which had followed the disaster at Majuba, were at last awakened by the ministerialist press to the necessity of vindicating British influence in South Africa, and the government soon found that, in spite of a highly articulate Radical minority, the feeling of the country was overwhelmingly behind them. It was not then realized either by the public or the government how seriously, and with what considerable justification, the Boers believed in their ability, if necessary, to sweep the British "into the sea." President Kruger had every expectation of large reinforcements from the Dutch in the two British colonies; he believed that, whatever happened, Europe would not allow Boer independence to be destroyed; and he had assured himself of the adhesion of the Orange Free State, though it was not till the very last moment that President Steyn formally notified Sir Alfred Milner of this fact. The Boers profoundly despised the military power of Great Britain, and there was no reason why they, any more than Germany or France, should contemplate the possibility of the empire standing together as a whole in such a cause. In England, on the other hand, it was thought by most people that if a firm enough attitude were adopted Mr Kruger would "climb down," and the effect of this error was shown partly in the whole course of the negotiations, partly in the tone personally adopted by Mr Chamberlain. It was only later that it was seen that if Great Britain intended effectually to champion the Uitlander cause, the moment for a test of strength had inevitably arrived. Negotiations could only bring the conflict a little nearer, delay it a little longer, or supply an opportunity to either side to justify its action in the eyes of the world. The conditions of the problem were such that unless Great Britain were to accept a humiliating rebuff, any correspondence, however skilfully conducted, was bound to bring into greater prominence the standing causes of offence between the two sides. The exchange of despatches soon led to a complete *impasse.* The persistent attempt of the South African Republic to assert its full independence, culminating in a formal denial of British suzerainty, made it additionally incumbent on Great Britain to carry its point as to the Uitlander grievances, while, from Mr Kruger's point of view, the admission of the Uitlanders to real political rights meant the doom of his oligarchical régime, and appeared in the light of a direct menace to Boer supremacy. The franchise, again, was an internal affair, in which the convention gave Great Britain no right to interfere, while if Great Britain relied on certain definite breaches of the convention, satisfaction for which was sought in the first place in such a guarantee of

[1] Dr W. J. Leyds, a Hollander born in Java in 1859, went out to the Transvaal in 1884 as attorney-general and was, in 1887, made government commissioner for the Netherlands (S. A.) railway. In 1890 he became state secretary and in that position was regarded as Kruger's right-hand man.

amendment as the Uitlander franchise would involve, the Boer answer was an offer of arbitration, a course which Great Britain could not accept without admitting the South African Republic to the position of an equal. Here was material enough for an explosion, even if personal misunderstandings and aggravations, adding fuel to the fire, had not naturally occurred (or even been deliberately plotted) during the negotiations. But the truth was that the Boers thought they stood to gain by fighting, while the British, though not expecting war, and acting up till the last month or so on the assumption that serious military preparations were either unnecessary or sufficiently unlikely to be necessary to make them politically inexpedient, had with no less confidence committed themselves to a policy which was impracticable on peaceful terms.

After July the tactics of the Boer executive were simply directed towards putting off a crisis till the beginning of October, when the grass would be growing on the veld, and meanwhile towards doing all they could in their despatches to put the blame on Great Britain. At last they drafted, on the 27th of September, an ultimatum to the British government. But, although ready drafted, many circumstances conspired to delay its presentation. Meanwhile, the British war office began to act. Certain departmental details were despatched to South Africa to form a working nucleus for military bases, and early in September the cabinet sanctioned the despatch to Natal from India of a mixed force, 5600 strong, while two battalions were ordered to South Africa from the Mediterranean. Sir George White was nominated to the chief command of the forces in Natal, and sailed on the 16th of September, while active preparations were set on foot in England to prepare against the necessity of despatching an army corps to Cape Town, in which case the chief command was to be vested in Sir Redvers Buller. Fortunately, although the draft of an ultimatum was lying in the state secretary's office in Pretoria, the Boers, unprepared in departmental arrangements which are necessary in large military operations, were unable to take the field with the promptitude that the situation demanded. They consequently forfeited many of the advantages of the initiative.

The military strength of the two republics was practically an unknown quantity. It was certain that, since the troublous times of 1896, the Transvaal had greatly increased its armaments; but at their best, except by a very few,[1] the Boers were looked upon by British military experts as a disorganized rabble, which, while containing many individual first-class marksmen, would be incapable of maintaining a prolonged resistance against a disciplined army. As was to be subsequently shown, the hostilities were not confined to opposition from the fighting strength of the two little republics alone; the British had to face Dutch opposition in their own colonies. The total fighting strength of the Boer republics is difficult to ascertain exactly. General Botha stated that there were 83,000 burghers from 15 to 65 years of age on the commando lists. Lord Kitchener put the total number of combatants on the Boer side at 95,000 (Cd. 1790, p. 13). The British official *History of the War* gave the number as 87,000; another calculation, based on the number killed, taken prisoner and surrendered, made the total 90,000. In the second (1901) rebellion of the Cape Dutch about 8000 joined the burgher forces. The number of Boers in the field at any one period was probably little more than 40,000. But the fact that it was to a large extent a struggle with a nation in arms doubled the numbers of the force that the Transvaal executive was able to draw upon. The bulk of the Dutch levies were organized on the burgher system—that is, each district was furnished with a commandant, who had under him field-cornets and assistant field-cornets, who administered the fighting capacity of the district. Each field-cornet, who, with the commandant, was a paid official of the state, was responsible for the arms, equipment and attendance of his commando.

[1] Lord Wolseley foresaw the strength of the Boers. Writing on the 12th of September 1899 he said, "If this war comes off it will be the most serious war England has ever had" (see *Military Life of the Duke of Cambridge*, ii. 421).

The plan of campaign which found favour with the Boers, when they determined to put their differences with Great Britain to the test by the ordeal of the sword, was to attack all the principal British towns adjacent to their own borders; at the same time to despatch a field army of the necessary dimensions to invade and reduce Natal, where the largest British garrison existed. It is not too much to suppose that the executive in Pretoria had calculated that the occupation of Durban would inspire the entire Dutch nation with a spirit of unanimity which would eventually wrest South Africa from the British. On paper the scheme had everything to recommend it as the expedient most likely to bring about the desired end. But the departmental executive could not launch the Natal invading force as early as had been anticipated, and it was not until the 9th of October that the ultimatum was presented to Sir (then Mr) Conyngham Greene, the British agent at Pretoria. The scheduled demands were as follow:—

The Ultimatum.

"*a.* That all points of mutual difference shall be regulated by the friendly course of arbitration, or by whatever amicable way may be agreed upon by the government with Her Majesty's Government.

"*b.* That the troops on the borders of this republic shall be instantly withdrawn.

"*c.* That all reinforcements of troops which have arrived in South Africa since the 1st of June 1899 shall be removed from South Africa within a reasonable time, to be agreed upon with this government, and with a mutual assurance and guarantee on the part of this government that no attack upon or hostilities against any portion of the possessions of the British Government shall be made by the republic during further negotiations within a period of time to be subsequently agreed upon between the governments, and this government will, on compliance therewith, be prepared to withdraw the armed burghers of this republic from the borders.

"*d.* That Her Majesty's troops now on the high seas shall not be landed in any part of South Africa."

To these demands the Transvaal government required an answer within 48 hours.

There could be only one reply, and on Wednesday, the 11th of October 1899, at five o'clock p.m., a state of war existed between the British government and the two Boer republics. On the following day the Boer attack on an armoured train at Kraaipan, a railway station in Cape Colony south of Mafeking and close to the western frontier of the Transvaal, witnessed the first hostile shot of a bloody war, destined to plunge South Africa into strife for two years and a half. (H. Ch.)

E. *The War of 1899-1902.*—For the purposes of history the South African War may be conveniently divided into five distinct periods. The first comprises the Boer invasion, terminating with the relief of Ladysmith on the 28th of February. The second, the period of Boer organized resistance, may be said to have finished with the occupation of Komati Poort in October 1900 (a month after Lord Roberts's formal annexation of the Transvaal) and the flight of President Kruger. The third may be characterized as a period of transition; it marks the adoption in earnest of a guerrilla policy on the part of the enemy, and an uncertain casting about on the part of the British for a definite system with which to grapple with an unforeseen development. This phase endured up to the failure of the Middelburg negotiations in March 1901. The next stage was that which saw the slow building up of the blockhouse system and the institution of small punitive columns, and may be considered to have extended until the close of 1901. The fifth, and last period—which, after all other expedients had failed, finally brought the residue of uncaptured and unsurrendered burghers to submission—was the final development of the blockhouse system, wedded to the institution of systematic "driving" of given areas, which operations were in force until the 31st of May 1902, when peace was ratified at Pretoria.

Stages of the War.

The first of these periods saw the severest fighting of the campaign. It opened with the investment of Mafeking by a Transvaal force under P. A. Cronje and the envelopment of Kimberley by Free State commandos under General Wessels. But these were minor operations. The main Boer effort was made in Natal, where their forces were commanded by P. J. Joubert, while Lieut.-General Sir George White was the British commander-in-chief. The northern part of Natal presented two faces of a triangle to the two enemies, the short base being formed by the Tugela river. Close to the head of the triangle at Dundee and Glencoe was posted a small British force under Major-General Sir W. Penn Symons. Against this force there advanced a Boer force under Lukas Meyer from the east, and, more slowly, the foremost portion of the main Boer army from the north, while at the same time other Transvaalers descended upon the railway between Glencoe and Ladysmith, and the Free Staters from the passes of the Drakensberg advanced towards Ladysmith, the British centre of operations at which the reinforcements sent from India gathered. On the 20th of October the Dundee brigade vigorously and successfully attacked Talana Hill, and drove back Lukas Meyer, but this success was dearly bought. Symons was mortally wounded, and 226 officers and men were killed and wounded. Half the mounted men lost their way in attempting to pass the enemy's flank and were taken, and the brigade, threatened to its left rear by Joubert's advance and by the force that had seized the railway, only escaped being enveloped by retreating upon Ladysmith, where it arrived in an exhausted state on the 26th of October. Meanwhile Sir George White had discovered the Boer force on the railway, and, though anxious on account of the advance of the Free Staters, on the 21st, stimulated by the news of Talana, he sent out a force of all arms under General (Sir John) French to drive the Boers from Elandslaagte and so to clear Symons's line of retreat. This was accomplished by French and his subordinate, Colonel (Sir) Ian Hamilton, in the action of Elandslaagte on the 21st of October (British losses, 258 all ranks). But on the 22nd the Free Staters' advance caused the victorious force to be recalled to Ladysmith, and the third action north of that town, Rietfontein (24th), was only a demonstration to cover the retirement of the Dundee force. By the 29th of October all the British forces at the front and their reinforcements had fallen in on Ladysmith, which the Transvaalers on the north and east and the Free Staters on the west side began to invest. Before the junction of the two allied wings was complete Sir George White attempted by a general attack to break up their line. The result of this decision was the battle of Lombard's Kop, outside Ladysmith, in which the whole of the available British force was engaged. The engagement was disastrous to the British, who had undertaken far too comprehensive an attack, and the Natal Field Force was obliged to fall back upon Ladysmith with the loss of 1500 men, including a large number of prisoners belonging to the left column under Lieut.-Colonel F.R.C. Carleton, who were cut off at Nicholson's Nek and forced to surrender by a mixed force of Transvaalers and Free Staters under Christian de Wet. From that day the rôle of the Natal Field Force was changed from that of a mobile field army into that of a garrison, and two days later it was completely isolated, but not before General French had succeeded in escaping south by train, and the naval authorities had been induced by Sir George White's urgent appeals to send into the town a naval brigade with a few guns of sufficient range and calibre to cope with the heavy position artillery which Joubert was now able to bring into action against the town.

Operations in Natal.

General Sir Redvers Buller, who had been appointed to the supreme command in South Africa as soon as it was perceived that war was imminent—his force being one army corps in three divisions, the divisional generals being Lord Methuen, Sir W. Gatacre and Sir C. F. Clery—arrived in Cape Town, ahead of his troops, on the day following Lombard's Kop. The situation which presented itself was delicate in the extreme. In Natal practically the whole of the available defence force was swallowed up by the steady success of the invasion; on the western frontier two British towns were isolated and besieged; and Boer commandos were on the point of invading Cape Colony, where the Dutch population seemed on the verge of rebellion. The army corps was about to arrive, practically as a whole unit, in South Africa; but it was evident that the exigencies of the situation, and the widely divided areas of invasion, would at least defer the execution of the plan which had been formed for an invasion of the Orange Free State from Cape Colony. The first duty was to effect the relief of the British forces which had been rendered immobile, and another duty imposed by political circumstances was to relieve Kimberley (where Cecil Rhodes was), while the prospect of rebellion forbade the complete denudation of the central part of the colony. Thus Sir Redvers Buller had no choice but to disintegrate the army corps. Clery and some brigades were sent to Natal; Gatacre with less than a brigade, instead of a division, was despatched to Queenstown, Cape Colony; while Lord Methuen, with a division, was sent off to relieve Kimberley. As November wore on, the situation did not improve. Cape Colony was invaded; while in Natal a flying column of Boers, pushing down from the Tugela, for a short time isolated the newly-arrived force under General (Sir) H. J. T. Hildyard, which opposed Joubert's advance on Pietermaritzburg at Estcourt. The situation in Natal seemed so serious that on the 22nd of November Sir Redvers Buller left Cape Town and sailed for Durban. In the meantime Lord Methuen had commenced his march to the relief of Kimberley. He encountered resistance at Belmont on the 23rd, but attacking resolutely he drove the Boers out of their strong positions. Two days later he won another action at Enslin. Still persevering he moved on to the Modder, where he was seriously opposed by De la Rey and P. A. Cronje, the latter having posted down from Mafeking with 2000 men and arrived on the previous night. The Boers, who held a river line, kept the British attack at bay all day, but eventually fell back, relinquishing the position after dark, as their right had been turned by General Pole-Carew's brigade. It was a long and wearing fight, in which the British lost 485 killed and wounded, and what was more serious, Lord Methuen (himself wounded) found that his force had exhausted its forward momentum, and that he would have to collect supplies and reinforcements on the Modder before fighting his next battle. The extent of the operations and the gravity of the situation now began to be felt in England; every available man was called up from the reserves, and the war office made what at the time appeared to be adequate provision for the waste which it was seen would occur. On the 30th of November the mobilization of a sixth division was ordered, offers of colonial aid were accepted, and every facility provided for local recruiting in the South African ports. Thus in the early days of December confidence was considerably restored. Buller was arranging for the relief of Ladysmith, which had already shown its spirit by two successful sorties against the besiegers' batteries. In every theatre the British strength was consolidating. But the full significance of the situation presented by these two small nations in arms had not yet been appreciated. The confidence restored by the lull during the early part of December was destined to be roughly shattered. On the 10th of December Gatacre essayed a night march and attack upon the enemy's position at Stormberg, and, misled by his guides in unknown ground, was himself surprised and forced to return with a loss of 719. On the following day Lord Methuen delivered an attack upon Cronje's position between the Upper Modder river and the Kimberley road, a line of kopjes called Spytfontein and Magersfontein. In a night attack on Magersfontein hill the Highland brigade came under heavy fire while still in assembly formation, and lost its general, A.G. Wauchope, and 750 men, and in the battle by day which followed the other brigades were unable to retrieve the failure, the total losses amounting to about 950. But even this could be suffered with equanimity, since Buller was about to bring his own force into play, and Buller, it was confidently supposed, would not fail. He had collected at Chieveley in Natal a brigade of mounted men, four brigades of infantry and six batteries of artillery, and he carried with him the trust alike of the army and the nation.

Buller's Arrival.

Failures of Methuen and Gatacre.

On the 15th of December Buller made his effort and failed. Behind the Tugela at Colenso were Louis Botha's forces covering the siege of Ladysmith, and, imperfectly acquainted with the topography, Buller sent a force to turn Botha's left, in conjunction with a frontal attack. But the flank attack became entangled in mass in a loop of the river and suffered heavily, and two batteries that formed part of the frontal attack came into action within a few hundred yards of unsuspected Boer trenches, with the result that ten guns were lost, as well as in all some 1100 men. Buller then gave up the fight. The full nature of the failure was not realized by the British public, nor the spirit in which the general had received the finding of fortune. He lost heart, and actually suggested to White the surrender of Ladysmith, believing this to be inevitable and desiring to cover White's responsibility in that event with his own authority; but White replied that he did not propose to surrender, and the cabinet at home, aware of Buller's despondency, appointed Field Marshal Lord Roberts to the supreme command, with Major-General Lord Kitchener as his chief of staff. A wave of military enthusiasm arose throughout the empire, and as the formation of a seventh division practically drained the mother-country of trained men, a scheme for the employment of amateur soldiers was formulated, resulting in the despatch of Imperial Yeomanry and Volunteer contingents, which proved one of the most striking features of the South African campaign. Pending the arrival of Lord Roberts and reinforcements, the situation in South Africa remained at a deadlock: the three besieged towns—Mafeking, Kimberley and Ladysmith—still held their own, but no headway was made by the relief columns; all they could do was to stand on the defensive. The only bright spot, as far as the British were concerned, was to be found in northern Cape Colony, where General French, with two cavalry brigades and details, by his skilful tactics and wonderful activity kept at arm's length a superior force of the enemy in the vicinity of Colesberg, an achievement the more noteworthy since he had pitted against him both De la Rey and De Wet, two of the three men of military genius produced by the war on the Boer side. On the 6th of January the Boers in Natal made a desperate attempt to storm Ladysmith. The garrison, though already weakened by privation and sickness, made a stubborn resistance, and after one of the fiercest engagements of the war, repulsed the attack at Caesar's Camp and Wagon Hill with severe loss to the enemy, itself having 500 casualties.

Buller's Failure. Lord Roberts sent out.

When Lord Roberts arrived in Cape Town on the 10th of January 1900 the three garrisons were still invested, and the relieving forces were still maintaining their rôle of passive resistance, while at the same time restraining the Dutch in Cape Colony. The commander-in-chief's first duty was to create a field army out of the tangle of units in Cape Colony. In the meantime, Sir Redvers Buller, who had been reinforced by Sir Charles Warren and the 5th division, essayed a second attempt to cross the Tugela, by turning the Boer left. But much time was consumed and the plan underwent several modifications before its execution began in earnest on the 16th of January. Warren was placed in command of the main body, which crossed the Tugela at Trichardt's Drift on the 17th and 18th. The mounted troops engaged a Boer force north-west of the point of passage, but were brought back to take part in a general right wheel of the forces of the Tugela, pivoting on Trichardt's Drift. But meantime the mobile enemy, whose original flank had been turned, had gathered at the new centre of gravity, and the upshot of several days' fighting was the retreat of the British. They had penetrated the enemy's right centre by the seizure of Spion Kop, but the force there became the target for the concentrated attacks of the Boers, and, after suffering heavily, was withdrawn (Jan. 24, 1900), with a loss of 1700 men.

Spion Kop.

By the 1st of February Lord Roberts had matured his plans and begun to prepare for their execution. On the 3rd of February he ordered a demonstration against the right of the Boer position at Spytfontein-Magersfontein to cover the withdrawal of General French and the cavalry from before Colesberg, and the concentration of his army at Modder River, disregarding another set-back in Natal to Sir Redvers Buller, who had against his advice made a third attempt to relieve Ladysmith on the 5th of February, and failed to make good the purchase which he secured across the Tugela (Vaal Krantz).

Lord Roberts's plan was first to concentrate to his left, taking every measure to induce the Boers to believe that the original scheme of invasion by the centre would now be resumed, and in this purpose he succeeded so well that his field army with the necessary transport for a cross-country march was assembled between the Orange and the Modder without serious mishap. Cronje at the new centre of gravity was not reinforced, all available Boers drawing down towards Colesberg. The concentration effected, Cronje still believed that the relief of Kimberley was the object of the gathering behind Modder River, and therefore held on to his Magersfontein kopje. The relief of Kimberley was indeed urgent, for dissensions between Rhodes and the military authorities had become acute. But to this part of the task only the cavalry division assembled under French was assigned. The army itself was to force Cronje into the open and then advance on Bloemfontein from the west. Roberts began his operations on the 11th of February. French started from Ramdam (near Graspan) eastward on that day, intending to make a wide sweep round Cronje's immobile army. Skirmishing with De Wet in the first stages of their ride, the cavalry brigades crossed the Modder at Klip Drift on the 13th. Cronje sent only detachments to oppose them, but these detachments were broken through by a sword-in-hand charge of the whole division, and Kimberley was relieved on the 15th. The infantry, meeting with great difficulties in its crossing of the Riet at Waterval owing to the country and its own unwieldy transport, followed $1\frac{1}{2}$ to 2 days later. But Cronje had now realized his danger, and slipped away westward behind French and in front of the leading infantry at Klip Drift. This was deflected by Kitchener westward to follow up the Boer rearguard, and after some delay the remainder of the infantry, at first fronting northwards, swerved westward likewise, while French from Kimberley, with such of his men as he could mount on serviceable horses, headed off Cronje in the north-west. The result, after one premature and costly assault on Cronje's lines had been made by Kitchener, was the surrender of 4000 Boers at Paardeberg with their leader on the 29th of February, the anniversary of Majuba. At the same moment came in news at last of the relief of Ladysmith.

Roberts's Advance.

Paardeberg.

It was part of Roberts's purpose to relieve the pressure in Natal by his own operations. Buller began his fourth advance on the 14th of February, and though this was checked the foothold gained was not abandoned, and a fifth and last attempt (Pieter's Hill) was successful. Ladysmith was relieved on the 28th of February. It had fared worst of all the beleaguered garrisons, and its 22,000 inhabitants were almost at their last gasp when relief came. The casualties from shell-fire had been few, but those from sickness were very heavy. Buller's operations, too, had cost at Colenso 1100 men, at Spion Kop 1700, at Vaalkrantz 400, and now in the last long-drawn effort 1600 more—over 5000 in all. But the tide of war had changed. The Natal invaders fell back to the mountains which enclose the north of the colony; Oliver and Schoeman retired from Cape Colony before the small forces of Gatacre and Clements; and the presidents of the republics, realizing that the British Empire was capable of more resistance than they had calculated upon, put forward feelers aiming at the restoration of the *status quo* before the war. These proposals were rejected by Lord Salisbury: there could be no end now but a complete destruction of the Boer power.

Relief of Ladysmith.

The surrender of Cronje and the relief of Ladysmith for the time being paralysed the Boer resistance. Two half-hearted attempts were made on the 7th and 10th of March, at Poplar Grove and Driefontein, to stem Lord Roberts's advance upon

Bloemfontein, President Kruger himself arriving on the scene to give confidence to his burghers; but the demoralization was so great that neither the military genius of the few nor the personal influence of the president could bolster up an adequate resistance, and on the 13th of March 1900 Lord Roberts's army marched into the Free State capital. This great move was persevered in and accomplished, in spite of the fact that at the very outset of the cross-country march (February 13) the great body of transport which had been collected at Ramdam had been cut off by De Wet (who had stayed on the Riet after French had shaken him off). It was therefore only made possible at all by reducing the rations of the fighting men to a minimum and by undertaking the risks of changing the line of communication three times. Naturally and necessarily the capture of Bloemfontein was followed by a period of reaction. It was not until the 29th of March that the new railway communication recommenced to feed the army. In the meantime rebellion had broken out in the Prieska district of Cape Colony, which was promptly quelled by Lord Kitchener. The halt at Bloemfontein was marked by the publication of proclamations, offering protection to the burghers, which, however, the invaders had not yet the power to fulfil. The enforced halt was unfortunate; it not only resulted in a bad outbreak of enteric, but it gave the Boers time to recuperate, and by the beginning of April they again took the initiative. The death of their commandant-general, Piet Joubert, on the 28th of March, seemed to mark a change in the fortunes of the Republican army. Christian De Wet, who had first come into prominence as the captor of Lord Roberts's convoy at Waterval, and was now operating east and south-west of Bloemfontein in order to counteract the influence of Roberts's numerous flying columns which rode hither and thither offering peace, added to his laurels by ambushing Broadwood's mounted brigade and horse artillery at Sannah's Post, just outside Bloemfontein, on the 31st of March. Four days later he reduced a detachment at Reddersburg, and then went south and invested Colonel Dalgety and a mixed force at Wepener, which was relieved after ten days by General Hunter's Ladysmith division, brought round to Aliwal North from Natal.

Capture of Bloemfontein.

These successes, if they retarded Roberts's progress, at least enabled him to rearrange his forces in accordance with the new situation at leisure, and to re-establish his transport, rail and wheeled, and on the 1st of May the main army moved northwards upon the Transvaal capital. The main advance was taken with one cavalry and three infantry divisions (the cavalry commanded by French, and the infantry divisions by Generals Tucker, Pole-Carew and Ian Hamilton). Rundle's division took the right of the advance; Methuen and Hunter moving from Kimberley, formed the left. Kelly Kenny, Colvile and Chermside held the communications based on Bloemfontein. A flying column detached from Hunter, under Mahon, in conjunction with Colonel H. C. O. Plumer's Rhodesian levies from the north, on the 17th of May relieved Mafeking, where Colonel (Lieut.-General Sir) R. S. S. Baden-Powell had throughout shown a bold front and by his unconventional gaiety as well as his military measures had held off the assault until the last. The same day the Natal Field Force under Buller moved up into the Biggarsberg and occupied Dundee. On the 10th of May Lord Roberts had crossed the Sand River; on the 12th of May he entered Kroonstad. After a halt of eight days at Kroonstad, the main army again moved forward, and, meeting but small resistance, marched without a halt into Johannesburg, which was occupied on the 31st of May, the Orange Free State having been formally annexed by proclamation three days earlier. On the 30th of May President Kruger fled with the state archives, taking up his residence at Waterval Boven on the Komati Poort line. The gold mines were now securely in the possession of the British, and on the 5th of June Lord Roberts's army occupied the capital of the Transvaal practically without resistance, setting free about 3000 British prisoners of war detained there.

Relief of Mafeking.

Capture of Pretoria.

It had been anticipated that the occupation of both the capitals would have brought the hostilities to a close, but this was not the case, and though after the 5th of June regular resistance was at an end, the army of occupation had still to face two years of almost unprecedented partisan warfare. On the 8th of June Sir Redvers Buller, who had made a long halt after the relief of Ladysmith and reorganized his army and its line of communication, forced his way over Alleman's Nek, and on the following day occupied Laing's Nek, the Natal gate to the Transvaal, while the field marshal fought a widespread battle against Botha, De la Rey and Kemp at Diamond Hill, 20 m. east of Pretoria. The object of this action was to push back the Boers from the neighbourhood of Pretoria, but no sooner was this done than the north-western Transvaal became active, in spite of Hunter's and Baden-Powell's advance from Mafeking through this district. As the British line of operations now extended eastward from Pretoria, the advance of these Boers to the Magaliesberg threatened their rearward communications, and as Buller had moved far more slowly than the main army there was not as yet an alternative line through Natal. Most serious of all was the pressure between Bloemfontein and the Vaal, where the Free Staters, under De Wet and other commanders, had initiated the guerrilla as soon as Botha and the Transvaalers retired over the Vaal and ceased to defend them by regular operations. Large forces had been left behind during the advance on Johannesburg for the protection of the railway and the conquered territory, and these were now reinforced from Kimberley and elsewhere as well as from detachments of the main army. These, under Sir Archibald Hunter and Sir Leslie Rundle, successfully herded Prinsloo with 4000 Free Staters into the Brandwater Basin (July 29)—a very satisfactory result, but one seriously marred by the escape of De Wet, who soon afterwards raided the Western Transvaal and again escaped between converging pursuers under Kitchener, Methuen, Smith-Dorrien, Ian Hamilton and Baden-Powell.

Diamond Hill.

Prinsloo's Surrender.

Before this Lord Roberts had initiated a movement from Pretoria to sweep down to Komati Poort on the Portuguese frontier. in which Buller, advancing across country from the south, was to co-operate. On the 26th to 27th of August the combined forces engaged and defeated Botha in the action of Belfast or Bergendal, with the result that the enemy dispersed into the bush-veld north of the Middelburg railway. On the 30th of August the remainder of the British prisoners were released at Nooitgedacht. On the 6th of September Buller, crossing the track of the main army at right angles, occupied Lydenburg in the bush-veld, and five days later the aged president of the republic took refuge in Lourenço Marques. On the 13th of September Barberton was occupied by French, and on the 25th Komati Poort by Roberts's infantry. From October the military operations were confined to attempts to reduce guerrilla commandos which had taken the field. Mr Kruger, deserting his countrymen, left for Europe in a Dutch man-of-war, and General Buller sailed for Europe. The Boer leaders definitely decided upon a guerrilla and a wearing policy, deliberately dispersed their field army, and then swelled and multiplied the innumerable local commandos. On the 25th of the month the ceremony of annexing the Transvaal was performed at Pretoria.

Flight of Kruger.

In November the prevailing opinion was that the war was over, and Lord Roberts, who had been appointed commander-in-chief at home, left South Africa, handing over the command to Lord Kitchener. Then followed a long period of groping for a means to cope with the development of guerrilla tactics, which for the next six months were at their zenith. The railway communications were constantly damaged, isolated posts and convoys captured, and the raiders always seemed able to avoid contact with the columns sent in pursuit. De Wet, after escaping from Brandwater Basin, was hunted north-westward, and crossed into the Transvaal, where, joining the local guerrilla bands, he surrounded an infantry brigade at Fredrikstad. But, unable to reduce it, and threatened on all sides, he turned back. On the 6th of November he was severely handled and his guns and wagons captured at Bothaville. But this misadventure only stimulated him. His emissaries roused the Free Staters west of Bloemfontein, and disaffection broke out in

Kitchener takes Command.

Raids by De Wet.

Cape Colony to an alarming degree, while, as forerunners of the promised invasion, scattered bodies of Free Staters crossed the Orange River to swell the rebellion. From Bothaville De Wet made for Thaba Nchu, where the Bloemfontein garrison held a cordon of posts. These were traversed on the 16th of November and the raiders passed on to Bethulie capturing Dewetsdorp and 500 men *en route*. Pursued closely and finding the rivers in flood De Wet hid some of his men under Kritzinger near the Orange and himself doubled back, traversing again the line of posts east of Bloemfontein. Kritzinger, Hertzog and bodies of Cape rebels raided Cape Colony as soon as they were able to cross the Orange, and Hertzog penetrated so far that he exchanged shots on the Atlantic coast with a British warship. All that the British forces under Sir Charles Knox and others could do was to localize the raids and to prevent the spread of rebellion. So far, however, energy and vigilance made them successful. Botha meanwhile held his own in the northern Transvaal, both against forces from Pretoria, Middelburg and Lydenburg, and against the Rhodesian Field Force under Sir F. Carrington, which had been sent up from Beira (by arrangement with the Portuguese) to southern Rhodesia. At the close of 1900 the commandos under the direct influence of Louis Botha attacked the railway posts on the Middelburg railway and captured Helvetia. De la Rey operated in the western Transvaal, and in concert with Beyers, whose presence in this region was not known to the British, he inflicted a sharp reverse on General R. A. P. Clements at Nooitgedacht in the Hekpoort valley on the 13th of December. Beyers then slipped away to the east, crossing the line between Johannesburg and Pretoria with impunity. Lord Kitchener called for more men, and on the 22nd of December the war office announced that 30,000 more mounted men would be despatched to the seat of war.

Botha's Successes.

With the opening of 1901 Lord Kitchener tried new schemes. He withdrew all his detached garrisons except in the most important centres, and set himself to make his railway communications perfectly secure. He determined to make the area of operations a waste, and instituted the concentration camps, into which he intended to bring the whole of the noncombatant inhabitants of the two republics. He despatched French with a large force to clear the south-eastern districts of the Transvaal and for the rest maintained a force to watch De Wet, and organized a defence force in Cape Colony, while using the residue of his mounted men to sweep the country of stock, forage and inhabitants. Although there were no great disasters, the new policy was not prolific in success. The enemy invariably dispersed before superior forces, and the removal of the women and children from the farms did not have the effect of disheartening the burghers as had been anticipated —it rather mended their vitality by relieving them of responsibility for their families' welfare. Nor were the Boer leaders destitute of comprehensive schemes. Botha arranged to penetrate Natal, De Wet to make a second attempt on the Colony, in connexion with Hertzog and Kritzinger. On the 10th of February De Wet, with five guns and 3000 men, carried out his promised invasion of Cape Colony. Passing the Bloemfontein-Thaba Nchu line a third time, he crossed the Orange to join Hertzog and rouse the Cape Dutch. But this invasion failed. By judicious use of the railway Kitchener concentrated sufficient troops in the colony to cope with the attempt, and, after being hunted for eighteen days, De Wet escaped back into the Orange River Colony with the loss of all his guns, munitions of war and half his force. In the northern Transvaal a force under Sir Bindon Blood cleared the country, but could not prevent Viljoen from escaping eastward to join Botha. Botha's activity in the south-east caused Kitchener to despatch a large force under French thither. This swept the country up to the Swaziland border. But Botha escaped. On the 3rd of March, after various raids and adventures in company with Smuts and Kemp, De la Rey, the lion of the western Transvaal, essayed an attack upon Lichtenburg, in which he was heavily repulsed. Signs of weakness were now apparent, and as a result Louis Botha, acting with the authority of Schalk Burger, the representative of President Kruger, opened negotiations with Kitchener. A meeting took place at Middelburg, Transvaal, on the 28th of February. These negotiations, however, broke down mainly over the treatment to be awarded to Cape rebels.

Concentration Policy.

The hostilities now entered upon a new phase. The establishment of a line of defensive posts between Bloemfontein and Ladybrand, though De Wet had three times traversed it, had given Kitchener an idea, and he resolved upon the scheme of fencing in areas by chains of blockhouses such as those already constructed for the protection of the railways. In the meantime, while these posts were under construction, the harrying of the commandos by mobile columns was continued. In March Babington, pursuing De la Rey after the latter's Lichtenburg misadventure, captured three guns and six maxims near Ventersdorp. In April Plumer occupied Pietersburg, the last remaining seat of government open to the enemy. Rawlinson captured a laager and guns at Klerksdorp, and, though neither De Wet nor De la Rey had been brought to book, matters had so far improved in May that municipal government was given to Johannesburg, and a certain number of mines were allowed to recommence working. Kemp was defeated by Dixon at Vlakfontein, after a desperate encounter. June brought little of moment, though the Boers scored two minor successes, Kritzinger capturing the village of Jamestown in Cape Colony, and Müller reducing a force of Victorians at Wilmansrust, south of Middelburg. In July there were further evidences of weakness on the part of the Boers, and Botha applied for permission to communicate with Kruger. This was allowed, but, as Kruger advised a continuance of the struggle, the slow course of the war continued. In the meantime, the concentration camps were becoming filled to overflowing, and a steady stream of captures and surrenders were reducing the hostile power of the republics.

Blockhouse Policy.

In August a proclamation was promulgated formally threatening the Boer leaders who should not surrender with permanent banishment from South Africa, but this proclamation had very little effect. Smuts, with a small force from the Magaliesberg, traversed Orange River Colony and stimulated the Cape rebels afresh. But September showed some slight improvement in the situation in Cape Colony, where French was in supreme command. On the 5th Scobell captured Lotter, who was subsequently executed for murder: though this was balanced a few days later by Smuts's successful attack on the 17th Lancers at Tarkastad. In the south-eastern Transvaal Botha made a new effort to invade Natal, but, although he captured 300 men and three guns in an action on the 17th of September at Blood River Poort near Vryheid, his plans were rendered abortive by his failure to reduce the posts of Mount Prospect and Fort Itala in Zululand, which he attacked on the 26th, and he only escaped with difficulty from the converging columns sent against him. Desultory fighting continued till the close of the year, the balance of success being with the British, though on the 30th of October Botha, returning from the south-east towards Pretoria, defeated Colonel Benson's column at Bakenlaagte, Benson being killed. About the same time, the force in front of De la Rey and Kemp in the west being depleted to find the troops for larger operations, the Boers made a fierce surprise attack on Colonel Kekewich's column at Moedville, in which Kekewich was wounded and his troops hard pressed for a time. De la Rey next attacked part of Methuen's column near Zeerust, but was repulsed (Oct. 24). Affairs again took an unsatisfactory turn in Cape Colony, and on the 8th of October the whole colony was placed under martial law. In November an unsuccessful attempt was made by several columns to run De Wet to earth in the Lindley district, whither, after his second raid on Cape Colony, he had returned. But in December matters improved. The reverse at Bakenlaagte was repaired by a force under Bruce Hamilton. This swept the south-eastern Transvaal as French had done, and with no better effect, for Botha escaped. But the British commander thereupon began a constant succession of night marches and raids which practically blotted out the resistance in the eastern Transvaal. The corps of National Scouts (formed of burghers who had taken the oath of allegiance) was inaugurated and the Johannesburg stock exchange reopened. By the end of the year the blockhouse system was complete, but this phase of the war was destined to close badly as De Wet on Christmas Eve captured a large force of Yeomanry at Tweefontein, west of Harrismith.

With 1902 the last phase of this protracted struggle commenced. The blockhouse system was practically finished, and Kitchener determined upon a new means of harassing the enemy, who still had a total of about 25,000 men in the field. But the blockhouses had already begun to serve the purpose for which they were designed. In the past the mobile columns, of which there were over sixty in the field, had always been bound to the railway for supply; now convoys could be pushed out to them along whatever blockhouse line they touched. In January Bruce Hamilton continued his successful night marches, and late in the month General Ben Viljoen was captured in the Leydenburg district. The only set-back was the descent which Beyers made upon Pietersburg, breaking into the concentration camp and carrying off a number of able-bodied refugees. Early in February Lord Kitchener commenced his first drive, and it was so successful that it was evident that the key to the situation had been found. First the country east of the line Bloemfontein-Vereeniging was swept four times over, then the method was employed in the Transvaal, east and west, and finally against the Cape rebels. There were a few small reverses, of which De la Rey's successful rush upon Paris's column and capture of Lord Methuen was the most important, but when some initial mistakes in the composition of the driving lines, which robbed the earlier drives of part of their effect, were made good, the system worked like a machine. The Boers were at last convinced of the futility of any attempt to prolong the struggle, and on the 23rd of March the representatives of the Boer governments came into Pretoria. Six weeks were spent in negotiation, and then a meeting of delegates, under the presidency of General Kemp, was held at Vereeniging.

The "Drives."

As a result of this conference articles of peace were signed at Pretoria on the 31st of May, and the South African war was a history of the past. The terms of peace may be condensed into the following points: (1) Surrender of all burghers in the field, with all arms and munitions of war; (2) all burghers duly declaring themselves subjects of King Edward VII. to be repatriated; (3) no burghers who should surrender to be deprived of either their liberty or property; (4) no proceedings to be taken against burghers for any legitimate acts of war during the period of hostilities; (5) the Dutch language to be taught in public schools on the request of parents, and to be allowed in courts of law; (6) sporting rifles to be allowed upon the taking out of licences; (7) the military administration to be superseded by civil administration as soon as possible, the civil administration to lead up to self-government; (8) the question of the native franchise not to be considered until after the introduction of self-government; (9) landed property not to be subjected to any special tax to defray the cost of the war; (10) a commission to be formed to facilitate the repatriation of the burghers, a grant of £3,000,000 being given as compensation for the destruction of farms.

Peace of Vereeniging.

In the whole war the British lost 5774 killed and 22,829 wounded, while the Boers lost about 4000 killed. The number of Boer prisoners in the hands of the British at the end of the war was about 40,000. (L. J.*; C. F. A.)

F. *From the Annexation to 1911.*—On the 4th of July 1900, a month after the occupation of Pretoria, a commission was issued to Lord Roberts authorizing him to annex the Transvaal. The proclamation of annexation was dated the 1st of September. Lord Roberts held the post of administrator of the colony until his departure for England in December following, when he was succeeded by Sir Alfred Milner, the high commissioner. It was not, however, until March 1901 that Milner, who resigned his governorship of Cape Colony, arrived at Pretoria to inaugurate a civil administration.[1] Hostilities were still proceeding, but in the areas under control Lord Milner (who was raised to the peerage in May) speedily set the machinery of government in motion. The civil administration of justice began in April; in October a reformed judicial system, with Sir J. Rose Innes as chief justice, was put into operation; in 1902 this was followed by the establishment of a supreme court. Besides law, the important departments of finance and mines were organized, and steps taken to remedy the grievances of the commercial and mining classes. Sir David Barbour, who had presided over a commission to inquire into the concessions granted by the late republic, presented a valuable report in June, and suggested a tax of 10% on the profits of the gold mining industry, a suggestion carried out a year later (June 1902). Meantime Johannesburg had been given a town council, and some of the gold mines permitted to restart crushing (May 1901). In November of 1901 the main body of the Uitlanders were allowed to return to the Rand. They had fled the country immediately before the outbreak of war and had been living at the seaports. While thus caring for the urban areas the administration was equally alive to the needs of the country districts. A commission which had been appointed to inquire into schemes of land settlement reported in June, and this was followed by the creation of a land board in December 1901. Lord Milner cherished the ideal of racial fusion by the establishment of British settlers on a large scale. He also recognized the necessity, if agriculture was to be developed, of an extensive system of irrigation, and Sir William Willcocks, formerly of the Egyptian Irrigation Department, was engaged to draw up a comprehensive scheme, having in view also the needs of the gold mines. Another department taken in hand was that of education; and the success which attended the opening of schools in the refugee camps was most striking. At the time the articles of peace were signed at Pretoria, more than 17,000 Boer children were being educated in these camps under the supervision of Mr E. B. Sargant.

The Work of Reconstruction.

This work of reconstruction was carried out in face of many difficulties other than those inherent to the undertaking. More than one plot on the part of Boers who had taken the oath of allegiance was hatched in Johannesburg, the most serious, perhaps, being that of Brocksma, formerly third public prosecutor under the republic. On the 15th of September 1901 Brocksma and several others were arrested as spies and conspirators. Letters to Dr Leyds and to Dr Krause of a treasonable character were found in Brocksma's possession, and being found guilty of high treason he was shot (30th of September). Krause, who was then in London, was arrested, tried and convicted for attempting to incite to murder, and sentenced to imprisonment. In November another conspiracy, to seize Johannesburg with the help of General De la Rey, was discovered and frustrated. More injurious than plots of this nature was the political agitation carried on in Cape Colony and in Great Britain. This agitation was directed with particular virulence against the high commissioner, whose recall, it was asserted, would remove the chief obstacle to peace. Mr J. X. Merriman and Mr J. W. Sauer came to England in the summer of 1901 on a mission from the Cape Africanders, and received much encouragement from Radical politicians. Nevertheless, much had been done to establish order and restart commerce by the time peace was made.

After the signature of the articles of peace the work of reconstruction was accelerated. The end of the military government was signalled by the assumption (on the 21st of June) by Lord Milner of the title of governor of the Transvaal and by the creation of an executive council. The Boer leaders unreservedly accepted British sovereignty. Generals Botha, De Wet and De la Rey, however, paid a visit to England (August–September, 1902) in an unsuccessful endeavour to get the terms of peace modified in their favour; they received little encouragement from a tour they made on the continent of Europe. On their return to South Africa the Boer generals and their colleagues aided to some extent in the work of resettlement, but the seats offered to the Boers on the executive council were declined. The work of repatriation and resettlement was carried out by commissioners acting in conjunction with a central advisory committee at Pretoria. These supplied the people with food, shelter, stock and implements. The burgher and native concentration camps were rapidly broken up; by December 1902 only 7600 out of 70,000 were left in the burgher camps.

At this period Mr Chamberlain determined to visit South Africa and use his personal influence to help forward the settlement of the country. After the almost total cessation of commerce during the war, there was in the last half of 1902 and the beginning of 1903 a great impetus to trade. When Mr Chamberlain reached the Transvaal in January 1903 the feeling among the British section of the community was optimistic. Mr Chamberlain was well received by the Boer leaders; it was, however, to the Rand magnates that he turned for financial help. That large sums were imperatively needed to accomplish the work of reconstruction was apparent. An agreement was reached whereby a loan of £35,000,000, guaranteed by the imperial government, was to be raised for the benefit of the Transvaal and the Orange River Colony; a further loan of £30,000,000 was to be issued in instalments of £10,000,000 and paid into the British exchequer as the Transvaal's contribution towards the cost of the war. The first instalment of this loan, to be issued in 1904, was guaranteed by the great mining firms of Johannesburg. With the proceeds of the first loan the debt of the South African Republic was paid off, the Transvaal and the Orange River Colony railways were bought by the state, and new railways and other public works were undertaken. The £3,000,000 granted by the articles of peace, and other considerable sums, besides £7,000,000 from the loan, were expended on repatriation and compensation.

The efforts made by the administration to restore the Boers to the land, to develop the material resources of the country,

[1] Milner became at the same time administrator of Orange River Colony. Several of the reforms adopted for the Transvaal applied to or affected the sister colony. (See ORANGE FREE STATE.)

and to remove all barriers to the intellectual and moral development of the people, were soon, however, hampered by severe commercial depression.

Economic Depression and Chinese Labour.

One of the least results of this depression was that the second war loan arranged by Mr Chamberlain was never issued, Great Britain finally (in 1906) abandoning all her claims. The commercial depression was due to many causes; of these the most apparent was the shortage of labour at the Rand mines. When work restarted after the war, the mine owners offered the Kaffir workmen little more than half the wages paid in 1898; but this effort at economy was abandoned, and the old rates of pay were restored in January 1903. Nevertheless, the labour available continued to be very much below the needs of the mines. The consequent small gold output meant a serious decrease of revenue, which was not compensated for by the heavy tax levied on the output of the Premier diamond mine, where operations began in 1903. Finally, to enable them to work their mines to their full capacity, the Rand houses asked for leave to import Chinese labourers.[1] Milner, anxious above everything else to obtain sufficient revenue to carry on his work of reconstruction, gave his consent to the experiment. The home government concurred, and during 1904–1906 over 50,000 Chinese were brought to the Rand on three-years' indentures. The objections to the introduction of the Chinese, urged in South Africa, in Great Britain and in other parts of the British Empire, are discussed under SOUTH AFRICA: *History*, § *D.*; here it need only be added that in the Transvaal the point upon which all parties were agreed was that no new racial or economic complications should be permitted; and these were guarded against by the restriction of the coolies to unskilled labour in the gold mines and by their compulsory repatriation. By the introduction of the Chinese the gold output from the mines was greatly increased, with the result that the Transvaal suffered less than any other part of South Africa from the restriction of commerce, which lasted for several years.

The discussions in the legislative council on the Chinese coolie question had been accompanied by a demand on the part of the Boers that such an important step should not be taken "without the constitutional approval of the white people of the Transvaal"; and after the importation of the coolies had begun, the agitation for the grant of representative institutions grew in volume. The British government was also of opinion that the time was near for the setting up of such institutions, and the pending grant of a constitution to the Transvaal was announced in parliament in July 1904. Meantime the existing (nominated) legislative council was dealing with another and a vital phase of the Asiatic question. There were in the Transvaal some 10,000 British Indians, whose right to "enter, travel or reside" in the country was secured by the London convention of 1884. Under republican rule these Indians—who were mainly small shopkeepers, but included some professional men of high standing—had suffered many restrictions, and their cause had been espoused by the British government.

Position of British Indians.

Nevertheless, under British rule their situation was in no way improved, and a determination was shown by the European inhabitants of the Transvaal further to restrict their privileges and at the same time to stop the immigration of other Indians. In this matter the Boer and British sections of the community were in agreement, and they had the support of the Transvaal government and of the other South African colonies. The problem was both economic and racial, and on both grounds South Africans showed a determination to exclude the competition of Indians and other Asiatics. Mr Alfred Lyttelton (who had succeeded Mr Chamberlain as secretary of state for the colonies) endeavoured to meet the wishes of the Transvaal by sanctioning legislation which would greatly restrict the immigration of Indians, but he would allow no tampering with the rights of Indians already in the colony. In 1907 the royal assent was given to bills restricting the immigration of Asiatics and providing for the registration of all Asiatics in the country.

Self-Government—the Botha Ministry.

In accordance with the promise made in 1904 a constitution for the Transvaal on representative lines was promulgated by letters patent on the 31st of March 1905; but there was already an agitation for the immediate grant of full self-government, and on the accession to office of the Campbell-Bannerman administration in December 1905 it was decided to accede to it. New letters patent[2] were issued (December 12, 1906), and the first general election (February 1907) resulted in the return of a majority belonging to *Het Volk*, a Boer organization formed for political purposes. (See further, SOUTH AFRICA: *History*, § *D.*) Sir Richard Solomon,[3] it was thought, might have formed a coalition cabinet, but he was among the defeated candidates. Lord Selborne, who had during 1905 succeeded Lord Milner as high commissioner and governor of the Transvaal, entrusted General Botha with the formation of a ministry. Botha chose as his colleagues Messrs J. C. Smuts (colonial secretary), Jacob de Villiers (attorney-general), H. C. Hull (colonial treasurer), J. F. B. Rissik (minister of lands and native affairs) and E. P. Solomon (minister of public works). These were all men of progressive, in some respects democratic, views, and in thus forming his cabinet General Botha showed his determination not to be dominated by the "back veld" Boers. Botha was strengthened in his attitude by the firm action of the Progressive (*i.e.* the ex-Uitlander) party, which secured 21 seats (out of a total of 69) in the legislative chamber, entirely in the Rand and Pretoria districts, and was led by Sir George Farrar and Sir Percy Fitzpatrick.[4] The government, which obtained an imperial guarantee for a loan of £5,000,000, announced that while there would be no wholesale repatriation of Chinese, the labour ordinance under which they were recruited would not be renewed, and by February 1910 all the Chinese coolies had returned home. At the same time successful efforts were made by the ministry to increase the supply of Kaffir labour for the mines. In the re-establishment of the field cornets and in other directions a return was made to the republican forms of administration, and on the education question an agreement satisfactory to both the British and Dutch-speaking communities was reached. Ample facilities were given for the teaching of Dutch, but it was provided that no pupil should be promoted to a higher standard unless he (or she) was making satisfactory progress in the knowledge of English.

The Union Movement.

One of the first problems which confronted the Botha ministry was the attitude to be adopted towards the other British colonies in South Africa. Lord Milner, by the creation of an inter-colonial board—which administered the railways of the Transvaal and Orange River Colony and controlled the constabulary of both colonies—and in other ways (*e.g.* the inclusion of the Transvaal in the South Africa customs union), had endeavoured to pave the way for federation. Mr Chamberlain when in South Africa in 1903 had also put forward federation as the desired goal. The existence of the inter-colonial council hampered, however, the freedom of the Transvaal government, and steps were taken to determine it.

[1] A careful summary of the facts regarding the shortage of labour and of the economic situation in the Transvaal at that time, together with the debates in the legislative council, will be found in *The Annual Register* for 1903, from the pen of Mr H. Whates.

[2] The letters patent provided, as to the Chinese coolies, that no further licences be issued for the introduction of indentured labour, and that none of the contracts be renewed.

[3] Sir Richard Solomon (b. 1850) was attorney-general of Cape Colony 1898–1900, attorney-general of the Transvaal 1902, and acting lieutenant-governor of the Transvaal 1905. He resigned office to contest a seat for the Transvaal parliament. Subsequently he was agent-general for the Transvaal in London, and (1910) agent-general for the Union of South Africa.

[4] Sir George Herbert Farrar (b. 1859) was a son of Charles Farrar, M.D., of Chatteris, England, and was a member of the Johannesburg Reform committee at the time of the Jameson Raid. He served in the war of 1899–1902, and was knighted in the last-named year. Sir James Percy Fitzpatrick (b. 1862) was a native of Cape Colony. He went to the Transvaal in 1884 and became honorary secretary to the Johannesburg Reform committee. He was the author of *The Transvaal from Within; Jock of the Bushveld*, &c.

Nevertheless, on economic as well as political grounds, the leaders of both parties in the Transvaal were prepared to consider favourably the proposals put forward by Dr Jameson at the close of 1906 for a closer union of all the self-governing colonies, and the first direct step to that end was taken at an inter-colonial conference held in May 1908. The history of this movement, which resulted in the establishment of the Union of South Africa on the 31st of May 1910, is given under SOUTH AFRICA: *History*, § *D*. Apart from this movement the most notable events in the Transvaal at this period were the development of agriculture,[1] the gradual revival of trade (the output of the gold mines in 1909 totalled £30,925,000, and at the end of the year 156,000 native labourers were employed), and the continued difficulty with regard to British Indians. Ministers declared their determination to keep the Transvaal a white man's country. With the example of Natal before them as a warning, it was (they argued) to the whites a question of life and death, and unless registration were enforced they could not prevent the surreptitious entry of new-comers. Attempts at compromise made in 1908 ended in failure. For failing to register Mr M. V. Gandhi and other leaders were imprisoned; and large numbers of Indians were deported. Notwithstanding the remonstrances of the Indian government, the imperial authorities could not effectively intervene; a self-governing colony (in which whites alone possessed the franchise) must be allowed to take its own course. By the end of 1909 it was stated that 8000 Indians—most of whom claimed the right of domicile—had been compelled to leave the country, while 2500 had been imprisoned for failure to comply with the Registration Act. The establishment of the Union of South Africa removed from the competence of the Transvaal provincial council all legislation specially or differentially affecting Asiatics. Thereupon the Union ministry was urged by the British government to effect a permanent settlement acceptable to all parties. The ministry replied (July 23, 1910) that whatever policy might be adopted regarding Indians legitimately resident in South Africa, unrestricted Indian immigration into the Transvaal would not be permitted (see Blue-book Cd. 5363).

When the Union was established General Botha became prime minister, two of his colleagues, Messrs Smuts and Hull, also joining the Union ministry. A fourth minister—Mr Rissik—was appointed first administrator of the Transvaal province, while a fifth minister, Mr E. P. Solomon, became a senator of the Union parliament. The elections to the Union House of Assembly, held in September, were notable as showing the strength of the Progressive (or Unionist) party. General Botha was defeated at Pretoria East by Sir Percy Fitzpatrick, and at Georgetown—a Rand constituency—Mr Hull was beaten by Sir George Farrar. Both ministers, however, subsequently secured seats elsewhere.

(F. R. C.)

TRANSVERSE RIB (Fr. *arc doubleau*), the term in architecture given to the rib of a vault which is carried across the nave, dividing the same into bays. Although as a rule it was sunk in the barrel vault of the Thermae, it is found occasionally below it, as in the Piscina at Baiae and the so-called Baths of Diana (Nymphaeum) at Nîmes. In the Romanesque and Gothic styles it becomes the principal feature of the vault, so much so that Scott termed it the master rib (see VAULT).

TRANSYLVANIA[2] (Lat. *Transsilvania*; Ger. *Siebenbürgen*; Hung. *Erdély*; Rumanian, *Ardeal*), a former principality (*Grossfürstentum*) occupying the extreme eastern portion of the kingdom of Hungary. It is bounded by Hungary proper on the W. and N., by Bukovina on the N.E. and by Rumania on the E. and S., and has an area of about 21,000 sq. m.

Transylvania has the form of an irregular circle, and is a high plateau of a mean altitude of 1000–1600 ft. above sea-level, surrounded on all sides by mountains. These are known under the general name of Transylvanian Mountains (*q.v.*), which are the south-eastern continuation of the Carpathian system, and fill the interior of the country with their ramifications. On the west or Hungarian side there are comparatively easy passes into the interior, but on the east and south frontiers the lofty mountains give Transylvania the aspect of a huge natural fortress. Among the highest peaks are Negoi (8345 ft.), Bucsecs (8230 ft.), Pietrosu (7544 ft.) and Königstein (7352 ft.). There are numerous valleys, ravines and cañons in the network of mountains covering the interior of the country. The principal plains are: in the valley of the Szamos near Dés and Besztercze (Bistritz); in the middle course of the Maros the beautiful Hátszeg valley; the fertile Cibin valley around Nagy-Szeben; the valley of the Aluta near Csik-Szereda, and the one extending from Reps to the Roteturm pass; and lastly the beautiful and fertile Burzenland in the vicinity of Brassó. The altitude of the valleys generally increases towards the east of Transylvania, the lowest depression being found in the western part of the Maros valley. Almost in the centre of the country lies a fertile plain about 60 m. in length and 50 m. in breadth, called Mezőség or

[1] The government expended over £1,000,000 on a land and agriculture bank and in 1910 made a grant of £100,000 towards the establishment of a college of agriculture at Pretoria.

[2] The Latin name appears first after the 12th century, and signifies "beyond the woods," *i.e.* from Hungary; the Hungarian and Rumanian name both mean "forest land." The German name is usually derived from the seven principal fortified towns or "burgs," founded by the German colonists, though some authorities prefer to connect it with the Cibin Mountains on the south frontier.

the Transylvania plain. The principal rivers of Transylvania, which are either tributaries of the Theiss, or flow direct into the Danube, are: the Maros, which rises in the mountains forming the eastern wall of Transylvania, and taking first a northern course flows through the country from east to west; its principal affluents are the Görgeny, the Great and Little Kokel or Nagy and Kis Küküllö, the Strell (Sztrigi) and the Cserna on the left, and on the right the Ampoly and the Aranyos, which is rich in auriferous sediments. The Aluta (Alt or Olt) rises not far from the Maros, but takes a southerly direction and pierces the Carpathians at the Roteturm pass, to enter Rumania; its principal tributaries in Transylvania are the Vargyas, the Homorod, the Cibin and the Burzen. The Szamos, formed by the junction of the Great (Nagy) and Little (Kis) Szamos, whose principal affluent is the Bistritz; the Zsil or Jiul; and the White and the Swift Körös are the other principal rivers. The largest lake of Transylvania is the Czeger or Hodosser See, 13 m. long, situated near Szamos-Ujvar, while a great number of small but beautiful mountain lakes are found. The climate of Transylvania is healthy; hot summers alternate with very cold winters, but the rainfall is not great. Transylvania abounds in mineral springs of all kinds, especially saline and chalybeate, the principal ones being found at Borszek, Elöpatak, Homorod, Rodna, Tusnád and Zaizon.

The principal occupations of the inhabitants are agriculture, cattle-rearing and mining. Of the total area of Transylvania 22·6% is arable land; 16·5% meadows and gardens; 9·5% pastures and 0·5% vineyards; while 37·3% is covered by forests and 13·5% is unproductive soil. The vegetation of Transylvania is luxuriant, except of course in the higher mountain zones. Fruits abound, as apples, pears, peaches, apricots, plums, cherries, chestnuts and almonds; mulberries are also cultivated. The vine flourishes best in the valley of the Maros. The chief crop is maize; but wheat, rye and other grains, potatoes, saffron, hemp, flax and tobacco are also grown. On the boundary mountains the trees are mainly coniferous; in the interior oaks, elms, beeches and ashes are conspicuous.

Bears, wolves, foxes, boars and various varieties of game are found, and on some of the mountains the chamois. There is abundant pasturage on which excellent cattle are reared; and in some districts buffaloes are bred for draught purposes. More important is the breeding of a sturdy race of horses, thousands of which are annually exported. The mountains maintain large flocks of sheep, of which two kinds are distinguished—with a fine short-stapled and a coarse long-stapled wool respectively. Silkworms are bred, and some silk is spun; and the export of honey and wax is not inconsiderable. Transylvania possesses the richest gold mines in Europe, and this metal is also "washed" in some of the streams, chiefly by gipsies. The gold is often found in conjunction with tellurium (first discovered in Transylvania in 1782) and is extracted principally at Nagyág, Kapnik-Bánya, Zalatna and Vöröspatak. In 1900 the value of the gold extracted was £300,000. Silver, copper, lead and iron are worked to some profit, while arsenic, alum, graphite, marble, porcelain, precious and building stones are also found. Coal is mined in the valley of the Zsil, but the abundance of timber has retarded its exploitation. Some of the saline springs yield salt enough to render their evaporation profitable. The principal places where salt is extracted are at Maros-Ujvár, Dés-Akna, Kolozs, Torda and Vizakna. In 1900 the value of the mineral products, except salt, was £1,000,000.

The industry of Transylvania, although not very developed, made some progress during the last quarter of the 19th century, and is mostly in the hands of the "Saxons." The principal branches are brewing, distilling, flour-milling, sugar, leather, paper, petroleum-refineries, cloth and earthenwares. The production of linen from flax and hemp is a home industry throughout Transylvania. The commerce is fairly active, and is mainly in cattle, dairy products, wood and wooden articles, and petroleum.

The population in 1900 numbered 2,456,838. Until 1848 the chief influence and privileges, as well as the only political rights, were divided among the three "privileged nations" of the Hungarians, Szeklers and Saxons. The first are the descendants of the Magyar conquerors. The Szeklers are of disputed origin, but closely akin to the Magyars (see SZEKLERS). The Saxons are the posterity of the German immigrants brought by King Geza II. (1141–1161) from Flanders and the lower Rhine to cultivate and repeople his desolated territories. At first these were known as Teutones, Teutonici Hospites and Flandrenses, but since the beginning of the 13th century the general name of "Saxons," as tantamount to "Germans," has prevailed. They are generally the most advanced section of the population. Their literary language is High German, but their spoken language is more of the Low German character. The Hungarians and Szeklers together number 814,994, and the Saxons 233,019, but by far the most numerous element, though long excluded from power and political equality, is formed by the Rumanians, 1,397,282 in number, who are spread all over the country. The gipsies of Transylvania, who are heard of under a voivode or prince of their own in 1417, are estimated at 50,000; many of them have taken to agriculture or gold-washing. Jews, Armenians, Bulgarians, Ruthenians and Greeks are also represented in the medley of peoples. The Magyars are mostly Roman Catholics or Unitarians, the Germans Protestants, and the Rumanians adherents of the Greek Church.

Transylvania, which was completely incorporated with Hungary in 1868, forms since 1876 one of the seven large administrative divisions into which Hungary was divided in that year. It was subdivided into fifteen countries, and contains the following principal towns: Kolozsvár, Brassó, Nagy-Szeben, Maros-Vásárhely, Besztercze, Fogaras, Torda, Segesvár, Gyula-Fehérvár, Dés, Szamos-Ujvár.

History.—Transylvania formed part of the Roman province of Dacia. After the withdrawal of the Romans the country became for centuries the prey of the various peoples who swept across it in their restless migrations. At the beginning of the 11th century (1004) Stephen I. of Hungary made himself master of the land, which was thenceforward governed as a Hungarian province by a voivode. As mentioned above, King Geza II. introduced German colonists, who founded Nagy-Szeben (Hermannstadt), and in 1211 King Andreas II. called in the German Teutonic orders, who settled in the Burzenland. These German colonists were granted special privileges, and founded many of the Transylvanian towns. As by the death of King Louis II. in 1526 the Hungarian crown fell to the house of Austria, the voivode John Zapolya succeeded in rendering himself independent. He and his successors, who were generally elected by the people, were supported by the Turks against the House of Austria, while the difficult nature of their country preserved them on the other hand from becoming too dependent on their powerful allies. After the defeat of the Turks at Vienna in 1683, their influence in Transylvania waned, and in 1699, by the peace of Carlowitz, the Porte acknowledged the suzerainty of Leopold I. of Austria over Transylvania. By the Leopoldine diploma of 1691 Leopold had guaranteed the ancient rights and laws of the land, and united it formally with the Hungarian crown. In 1765 Maria Theresa made it a grand principality (Grossfürstentum). The efforts of the Rumanian inhabitants to secure recognition as a fourth "nation," and the opposition of the non-Magyar population to a closer union with Hungary, led to troubles early in the 19th century, culminating in 1848. In 1849 Transylvania was divided from Hungary by an imperial decree, and became an Austrian crown-land; but in 1860 Transylvania became an autonomous province, with a separate Diet, and a high executive power of its own. The Diet assembled in Nagy-Szeben in 1863 decreed the complete separation from Hungary, the union with Austria, and the recognition of the Rumanians as the "fourth nation." But the Hungarian government did not recognize this Diet, and the Diet assembled at Kolozsvár in 1865, in which the Hungarians had the majority, decreed again the union with Hungary. By the compromise of 1867 Austria granted the union of Transylvania with Hungary, which was completed in 1868. Transylvania lost every vestige of autonomy, and was fully and completely incorporated with Hungary. Since that time the Magyarization of the principality has steadily been carried through, in spite of the bitter protests and discontent of both the Saxons and Rumanians. A Hungarian university was founded at Kolozsvár in 1872; and Hungarian is recognized as the official language.

Teutsch, *Geschichte der Siebenbürger Sachsen* (2 vols., 3rd ed., Hermannstadt, 1899).

TRANSYLVANIAN MOUNTAINS, the general name of the mountain system which surrounds the Transylvanian highland or plateau on all four sides, and forms the south-eastern and southern continuation of the Carpathian system (*q.v.*). At the mouths of the Visó and the Golden Bistritza, where the

Eastern or Wooded Carpathians end, the range of mountains divides and sends ramifications in two directions, to the south and to the west. These chains which enclose Transylvania, giving it the general aspect of a great natural fortress, are the most eastern offshoots of the mountain system of central Europe, and guard the approach from the east to the great Hungarian plain. They slope gently towards the interior of Transylvania, but rather abruptly towards Rumania, and while the western wall possesses several large and easy passes, the eastern and southern walls are much more difficult to cross.

The eastern wall of the Transylvania quadrilateral is composed of two parallel ranges of mountains divided by the valleys of the Maros and Aluta. The outer range is composed of the following groups: the Gyergyó Mountains (including the Kelemen range) with the highest peaks Kelemenhavas (6600 ft.) and Pietrosul (6908 ft); the Csik Mountains with the highest peaks Nagy-Hagymas (5900 ft.) and the volcanic Büdös (3300 ft.); and the Bereczk Mountains with the highest peak Lakócza (5830 ft.). The inner range is composed of the following groups: the Görgény Mountains with the highest peak Mezőhavas (5826 ft.); the Hargitta Mountains with the highest peak Hargitta (5900 ft.); and the Barota Mountains with the highest peak Kukukhegy (5120 ft.). Near the mouths of the Maros and the Aluta are situated the celebrated Györgyö valley, one of the most beautiful in the whole Transylvania, and the famous Borszék valley with its mineral springs.

The southern wall of the Transylvanian highland is occupied by the Transylvanian Alps. They have a length of 230 m., and are the highest and wildest mountain range of the whole Transylvanian system, resembling the High Tatra in their bold and high peaks, their beautiful scenery, and their flora. The Transylvanian Alps rise to an altitude of 7200 ft. above the level of the Danubian (Rumanian) plain, and are divided into a considerable number of groups. From east to west these groups are: the Bodza Mountains with the highest peak Csukás (Ciucas, 6424 ft.); the Burzenland Mountains with the beautiful peaks of Bucsecs (8230 ft.), Königstein (7352 ft.) and Schuler (5910 ft.); the high Forgaras group, extending to the Roteturm pass, and containing Negoi (8345 ft.), the highest peak in the Transylvanian mountains, Butyan (8230 ft.) and Surul (7482 ft.). West of the Roteturm pass the Transylvanian Alps are also known under the name of the Hátszeg Mountains, and consist of the following groups: the Cibin Mountains with the highest peak Cindrel (7366 ft.); the Paringul Mountains with the highest peak Mandra (8260 ft.); the Vulkan Mountains, and the Hátszeg Mountains proper with the beautiful peak Retiezat (8125 ft.). The south-western part of the Transylvanian Alps is formed by the Cserna or Ruszka Mountains with the highest peak Verfu Petri (8140 ft.) whose offshoots, of a mean altitude of 3200–4700, known as the Banat Mountains, fill the Banat. The southern part of the Cserna Mountains, known as the Stretinye Mountains, extend to the Danube, and together with the Miroch Mountains, on the right side of the Danube, and belonging, therefore, to the Balkan system, form the famous gorge of the Iron Gate near Orsova.

The western and northern wall of the Transylvanian quadrilateral do not present the character of an uninterrupted chain of mountains, but possess many low and easy passes towards the Hungarian plain. Going from south to north the principal groups are: the Transylvanian Ore Mountains with the basaltic mass of the Detunata (3768 ft.) near Abrudbánya; the Bihar Mountains, with romantic scenery and numerous caverns, with the highest peak the Cucurbeta (6045 ft.); to the east of this group are the Aranyos Mountains with the highest peak, the Muntelui Mare (5970 ft.), to the south-west of Kolozsvár; then come the Meszes group and the Kraszna Mountains. The northern wall is formed by the Lápós Mountains with the highest peak Ciblesiu (6020 ft.), and the Rodna Mountains with the highest peaks Muncsel (5835 ft.), Pietrosu (7544 ft.) and Ineu (7484 ft.).

Inside this mountainous quadrilateral lies the Transylvanian highland or plateau, which has a mean elevation of 1000–1600 ft. It is improperly called a plateau, for it does not possess anywhere extensive plains, but is formed of a network of valleys of various sizes, ravines and cañons, united together by numerous small mountain ranges, which usually attain a height of 500–800 ft. above the altitude of the valley.

In the Transylvanian Mountains the principal passes are: the Rodna, the Borgo, the Tölgyes and the Békás. Then come the Gyimes, the Uz and Oitoz, the Bodza or Buzeu, the Tömös or Predeal pass, crossed by the railway from Brassó to Bucharest, the famous Roteturm pass (1115 ft.) through the narrow gorge of the Aluta, crossed by the railway from Nagy-Szeben to Bucharest, the Vulkan, the Teregova pass, and the Iron Gate pass, both crossed by the railway from Temesvár to Craiova. All those passes lead from Transylvania into Rumania. From Transylvania into Hungary are the Bánffy-Hunyad pass, crossed by the railway from Nagy-Várad to Kolozsvár, and the defile of the Maros crossed by the railway from Arad to Broos. In the interior of Transylvania are the Szent-Domokos pass near Csik-Szereda leading from the valley of the Aluta to that of the Maros (near their respective mouths), and the pass of Csik-Szereda over the Hargitta Mountains.

TRAP (O. Eng. *treppe* or *traēppe*, properly a step, as that on which an animal places its foot and is caught, cf. Ger. *Treppe*, flight of stairs), a mechanical device for the snaring or catching anything, and especially wild animals. Traps for animals are of great antiquity, and no savage people has ever been discovered, whatever its culture scale, that did not possess some variety of snare. In the most primitive form of trap no mechanism need be present, *e.g.* a cavity into which the animal walks, as the pitfall of the Arabs and Africans or the snow-hole of the Eskimos. Dr O. T. Mason has divided traps into three classes: *enclosing* traps, which imprison the victim without injury; *arresting* traps, which seize the victim without killing it, unless it be caught by the neck or round the lungs; and *killing* traps, which crush, pierce or cut to death.

Enclosing traps include the pen, cage, pit and door-traps. Pen-traps are represented by the fences built in Africa into which antelopes and other animals are driven; and by fish-seines and pound-nets. Among cage-traps may be mentioned bird-cones filled with corn and smeared with bird-lime, which adhere to the bird's head, blinding it and rendering its capture easy; the fish-trap and lobster-pot; and the coop-traps, of which the turkey-trap is an example. This consists of a roofed ditch ending in a cul-de-sac into which the bird is led by a row of corn-kernels. Over the further end a kind of coop is built; the bird, instead of endeavouring to retrace its steps, always seeks to escape upward and remains cooped. Pitfalls include not only those dug in the earth, at the bottom of which knives and spears are often fixed, but also several kinds of traps for small animals. One of these consists of a box near the top of which a platform is hung, in such a way that, when the animal leaps upon it to secure the bait, it is precipitated into the bottom of the box, while the platform swings back into place. Another kind of pitfall is formed of a sort of funnel of long poles, into which birds fall upon alighting on a perfectly balanced bar, to which a dish of corn is made fast. The door-traps form a large and varied class, ranging in size from the immense cage with sliding door in which such beasts as tigers are caught, to the common box-trap for mice or squirrels, the door of which falls when the spindle upon which the bait is fixed is moved. The box-trap with a simple ratchet door, allowing the animal or bird to push under the door or wires which fall back and imprison them, is alike an enclosing and an arresting trap. There are four general classes of arresting traps, the mesh, the set-hook, the noose and the clutch. The mesh-traps include the mesh and thong toils used of old for the capture of the lion and other large game, and the gill-net in the meshes of which fish are caught by the gills. To the set-hook division are reckoned the set-lines of the angler, several kinds of trawls and the toggle or gorge attached to a line, which the animal, bird or fish swallows only to be held prisoner. The noose-trap class is a very extensive one. The simplest examples are the common slip-noose snares of twine, wire or horsehair, set for birds or small mammals either on their feeding grounds or runways, the victim being caught by the neck, body or foot as it tries to push through the noose. When the noose is used with bait it is generally attached to a stout sapling, which is bent over and kept from springing back by some device of the "figure-4" kind. This is constructed of three pieces of wood, one of the horizontal spindle on which the bait is placed, one of the upright driven into the ground, and the third the connecting cross-piece, fitted to the others so loosely that only the strain of the elastic sapling keeps the trap together. When the victim tries to secure the bait he dislodges the cross-piece and is caught by the noose, which is spread on the ground under the bait. The Patagonians take the vicuna with one variety of this snare, and, before the moose (*Cervus alces*) was protected by law in North America, even that animal, weighing often 1200 lb, was caught in snares of wire and rope. There are two widely different types of clutch-traps: bird-lime and other tenacious substances, and jaw and clap-traps. The simplest form of the first is adhesive fly-paper. A common practice in Italy is to smear with bird-lime the branches in the neighbourhood of a captive owl, which results in the capture of numbers of birds, gathered to scold at their common enemy. Examples of the clap-trap are the clap-net, consisting of two nets laid flat on the ground and attached to cords in such a manner that they fly up and close when the draw-cord is pulled by a concealed trapper; and the various other spring-traps used by bird-catchers. The jaw-traps are the most important class of device for the capture of fur-bearing animals, and are the product of civilization. While rude specimens are known to have existed in the middle ages, the *steel-trap* as used to-day dates from the middle of the 18th century, and reached perfection in the latter half of the 19th, the "Newhouse," named from the American inventor, having been the first trap of high grade. Steel-traps consist of two jaws, with or without teeth, which are worked by powerful single or double springs and are "sprung" when the victim steps upon the "pan," which is placed between the jaws and attached to a lever. They are made in many sizes, from the smallest, designed for rats, to the "Great Bear Tamer," weighing over 40 lb, with jaws of 16 in. in which lions, tigers and grizzly bears are trapped. The steel-trap is set and concealed in such a manner that the animal must step on its pan in passing over it to secure the bait. In trapping such wary animals as the sable, marten, mink, otter or beaver, great care is taken to obliterate all signs of the trap and of human presence, the scent of the hands being neutralized by smoking the traps or avoided by the use of gloves. In North America castoreum, musk, asafoetida, oil of anise and common fish-oil are used to entice the victims to the traps. Trails of some one of these scents are laid from different directions to the trap.

With the clutch-traps must also be reckoned the oldest form of steel-trap, now to be seen only in museums, the man-trap, which was used first about the middle of the 18th century when the systematic preservation of game rendered protection against poachers a necessity. Such a trap, from Gloucestershire, is over 6 ft. long, has 19-in. serrated jaws and weighs 88 lb. Another form of man-trap, the spring-gun, belongs to the next category, the killing traps, which are divided into traps of weight, point and edge. The most important of the weight class is the dead-fall, of which the typical form consists of a pen over whose narrow entrance one or more logs are laid across a lighter log, which is balanced upon a spindle necessarily struck by the entering animal, causing the logs to fall upon its back. In some cases the bait is attached to the spindle itself. The dead-fall was always the favourite trap of the American Indians, and is in use among many aboriginal tribes in Africa and South America. A slab of stone is often used as a weight. The common mouse-trap which kills either by a blow or strangulation is a variety of dead-fall. Of point-traps may be mentioned those of the impaling and the missile classes. An example of the former is the stake or spear placed by Arab and African tribes at the bottom of pitfalls for big game. Another impaling trap common in Africa is the harpoon down-fall, generally used for the hippopotamus. It consists of a heavily weighted harpoon suspended in such a way that the animal, passing beneath, breaks a cord and precipitates the harpoon upon itself. Another example of impalement is the hawk-trap, consisting of a circle of stout sharp wires, in the centre of which a live fowl is placed. A bird of prey attempting to secure the fowl is impaled upon the wires. Of missile traps the most universal are the ancient springbow and its modern representative the spring-gun. This is fixed upon stakes, or against a tree, with a line attached to the trigger and stretched immediately in front of the muzzle. An animal pressing against the string pulls the trigger and discharges the piece into its own body. An arrangement of sticks holding the bait in front of the muzzle is sometimes substituted for the string. Of edge-traps a curious example is the wolf-knife of Western America, which consists of a very sharp blade embedded in frozen fat. One of the wolves, licking the fat, cuts its tongue and a flow of blood ensues, with the result that not only the wolf itself but its companions become infuriated by the smell and taste, and the wounded beast, and often many of the others, are killed and devoured. The Alaskan knife-trap for large game consists of a heavy blade attached to a lever, which, when released by the animal biting at the bait, flies over and kills the victim.

See *Shifts and Expedients of Camp Life*, by W. B. Lord (1871); *Camp Life and the Tricks of Trapping*, by W. H. Gibson (1902); O. T. Mason, "Traps of the American Indians," *Annual Report*, Smithsonian Institution, for 1901; *The Story of the Trapper*, by A. C. Laut (1903).

TRAPANI (anc. *Drepanum*), a city and episcopal see of Sicily, capital of the province of the same name, situated on the west coast, 3 m. W. of the Monte San Giuliano, which rises above it, 121 m. W. by S. of Palermo by rail, and 47 m. direct. Pop. (1906), town 47,578, commune 68,986. The ancient Drepanum (δρέπανον, a sickle, from the shape of the low spit of land on which it stands) seems originally to have been the port of Eryx, and never to have been an independent city. It is represented by Virgil in the *Aeneid* as the scene of the death of Anchises, but first appears in history as an important Carthaginian naval station in the First Punic War (about 260 B.C.), part of the inhabitants of Eryx being transferred thither. Near Drepanum the Roman fleet was defeated in 250 B.C., while the struggle to obtain possession of it ended in the decisive Roman victory off the Aegates Islands in 241, which led to the conclusion of peace (see Punic Wars). It continued to be an important harbour, but never acquired municipal rights. Under the Norman kings, at the time of the first crusade, it became a place of importance; while it was a residence of the Aragonese kings. In the 16th and 17th centuries it was strongly fortified. In 1848 it was the first Sicilian city to rise against the Bourbons.

No remains of the classical period exist except a portion of the mole. There are some fine Gothic and baroque palaces, and a few churches with interesting details. The Oratorio S. Michele contains wooden groups representing scenes from the Passion, executed in the 17th century and used for carrying in procession. On the tiled pavement of Sta Lucia is an interesting view of Trapani, showing the strong fortifications on the land side, which have been demolished to permit of the extension of the town in that direction. The Madonna dell' Annunziata, about 1½ m. east of the town, founded in 1332, is now restored to its original style. The adjacent Cappella del Cristo Risorto contains a statue of the Virgin and Child in marble said to have been brought from Cyprus, to which an immense number of valuable offerings have been made, among them two bronze candelabra and a model of the city in silver; while the statue itself is hung with jewels, necklaces, cameos, rings, watches, &c. The modern town is clean and well built, with a fine esplanade on the south. It is a harbour of considerable importance. It was entered by 144 vessels, representing a tonnage of 129,164 in 1906. The imports showed a value of £276,674, the most important items being wheat, coal and timber; while the exports amounted to £143,347, the chief items being salt, wine, salt fish and building-stone. There are also large salt-pans to the south of the city, extending along the coast as far as Marsala, which produce about 200,000 tons of salt annually, of which in 1906 121,192 tons were exported, chiefly to Norway, Sweden, Canada and the United States. The numerous windmills are used for grinding the salt. (T. As.)

TRAP-BALL, or Knur and Spell (M. Eng. *knurre*, knot; Dan. *spil*, spindle), an old English game, which can be traced back to the beginning of the 14th century, and was commonly played in northern England as late as 1825, but has since been practically confined to children (bat, trap and ball). It was played with a wooden trap, by means of which a ball (knur) of hard wood about the size of a walnut was thrown into the air, where it was struck by the player with the "trip-stick," a bat consisting of two parts: the stick, which was of ash or lancewood and about 4 ft. long, and the pommel, a piece of very hard wood about 6 in. long, 4 in. wide and 1 in. thick. This was swung in both hands, although shorter bats for one hand were sometimes used. Originally the ball was thrown into the air by striking a lever upon which it rested in the trap; but in the later development of the game, usually called knur and spell, a spell or trap furnished with a spring was used, thus ensuring regularity in the height to which the knur was tossed. The object of the game was to strike the knur the greatest possible distance, either in one or a series of strokes.

TRAPEZE, or Trapese, a form of swing, consisting of a cross-bar suspended by ropes and used for gymnastic exercises, acrobatic displays and the like. The name was so applied in French (*trapèze*) from the resemblance of the apparatus to a "trapezium" or irregular four-sided figure. The Greek τραπέζιον is a diminutive of τράπεζα, a table, literally a four-footed or four-legged object, being a shortened form of τετράπεζα (τετρα-, four, and πέζα, foot).

TRAPEZOPHORON, the Greek term (from τράπεζα, table, and φέρειν, to bear) given to the leg or pedestal of a small side table, generally in marble, and carved with winged lions or griffins set back to back, each with a single leg, which formed the support of the pedestal on either side. In Pompeii there was a fine example in the house of Cornelius Rufus, which stood behind the impluvium. These side tables were known as *mensae vasariae* and were used for the display of vases, lamps, &c. Sometimes they were supported on four legs, the example at Pompeii (of which the museums at Naples and Rome contain many varieties) had two supports only, one at each end of the table. The term is also applied to a single leg with lion's head, breast and forepaws, which formed the front support of a throne or chair.

TRAPPISTS, Cistercian monks of the reform instituted by Armand J. le B. de Rancé (*q.v.*), abbot of La Trappe, 1664. La Trappe was a Cistercian abbey near Soligny, in the diocese of Sées, in Normandy, founded 1140. It suffered grievously from the English wars and from commendatory abbots, so that towards 1650 the community was reduced to half a dozen monks who had long ceased to comply with the obligations of their state, and were an open scandal to the neighbourhood. Armand Jean de Rancé became commendatory abbot at the age of ten, 1636; and on his conversion from a worldly life he began to interest himself in his abbey and conceived the project of restoring the monastic life therein, 1662. With this object he visited La Trappe, but the monks were recalcitrant and threatened his life; through the intervention of Louis XIV. he was able to pension them off; they were replaced by a community of Cistercians of the strict observance, and the monastic buildings, which had fallen into ruin, were repaired at de Rancé's expense. He himself then entered the novitiate in one of the reformed Cistercian abbeys, and on his profession he came to La Trappe as regular abbot, 1664. But he desired a return to the full programme of the primitive Cistercians. His influence with Louis XIV. and with the court of Rome secured him a free hand in carrying out changes without trammel from the Cistercian superiors, who looked askance at the project; and he was able to persuade his community to adopt a manner of life beyond the original Cistercian practice, and far beyond St Benedict's rule. Thus they abstained wholly from wine and fish, and rarely ate eggs; on certain days they had only bread and water, and on two days in the year they went barefooted; and they slept in their day clothes: these practices are in contradiction to what St Benedict allowed. On the other hand manual labour occupied only $3\frac{1}{2}$ hours, but the church services 7—herein reversing St Benedict's apportioning of the time. In short, the Trappist régime is probably the most penitential that has ever had any permanence in the Western Church. Yet it attracted vocations in such numbers that de Rancé had 300 monks under him. Through age and ill health he resigned his abbacy in 1695, and died five years later.

During the 18th century La Trappe continued faithful to de Rancé's ideas, but the observance spread only into two monasteries in Italy. It was the dispersal of the community at the French Revolution that turned the Trappists into a congregation in the Cistercian order and finally into a separate order. Dom Augustine de Lestrange, the novice-master at the time of the suppression in 1790, kept twenty of the monks together and obtained permission for them to settle at Val-Sainte in Fribourg, Switzerland. Here they made their life still stricter than that of La Trappe, and postulants flocked to them in such numbers that in two years' time colonies went forth to establish Trappist monasteries in England, Belgium, Piedmont, Spain and Canada; and in 1794 Dom Augustine was named by the Holy See Father Abbot of all these foundations, thus formed into a congregation. In 1817 they returned to La Trappe, many new foundations were made, and by Dom Augustine's death in 1827 there were in all some seven hundred Trappist monks. In the course of the century three or four congregations arose—a Belgian, an Italian, and two in France—each with a vicar subject to the general of the Cistercians. In 1892 these congregations were united into a single Order of Reformed Cistercians, or of Strict Observance, with an abbot-general resident in Rome and independent of the general of the Cistercians of the Common Observance. In 1898 the Trappists recovered possession of Citeaux, the mother-house of the Cistercians, secularized since the Revolution, and it was declared by Rome to be the head and mother house of the Reformed Cistercians, who thus were recognized as the authentic representatives of the primitive Cistercian movement.

The Trappists are a thriving and vigorous order. In 1905 they had 58 monasteries with 1300 professed choir monks and 1700 lay brothers. At the time of the recent expulsions (1903) they had twenty houses in France, and they have two or three in all the countries of western Europe, including England (Mount St Bernard, near Leicester) and Ireland (Mount Mellery in Waterford and Roscrea); also in the United States and in Canada. Besides they have a house in China, with over fifty Chinese monks; one each in Japan, Asia Minor, Palestine, Bosnia and Dalmatia, and four in various parts of Africa. The abbey of Mariannhill in Natal is devoted to the christianizing and civilizing of the Kaffirs; there are numerous stations with elementary schools and chapels, and at the abbey is a high school and printing-press for books in the Zulu and Basuto languages. In heathen countries the Trappists now give themselves up to missionary work and the task of civilizing the natives.

The first Trappist nunnery was the abbey of Les Clairet, near Chartres, which de Rancé persuaded to adopt his reforms. Dom Augustine de Lestrange established another in 1796, and now there are fifteen with 350 choir nuns and 500 lay sisters. One is in England at Stapehill, near Wimborne, founded in 1802. The manner of life of the nuns is almost the same as that of the monks.

See the *Lives* of de Rancé. A minute account of the observance is in de Rancé's *Règlemens de la Trappe* (1701). The beginning of the reform is told by Helyot, *Histoire des ordres religieux* (1718), vol. vi. ch. 1; the developments under Dom Augustine de Lestrange are described in the supplementary matter in Migne's *Dictionnaire des ordres religieux* (1858). The whole subject is well treated by Max Heimbucher, *Orden u. Kongregationen* (1907), vol. i. § 48; and in Wetzer und Welte, *Kirchenlexicon* (2nd ed.), and Herzog, *Realencyklopädie* (3rd ed.). A realistic and sympathetic picture of Trappist life is the redeeming feature of J. Huysman's *En route*. (E. C. B.)

TRAQUAIR, SIR JOHN STEWART, 1st Earl of (d. 1659), Scottish statesman, was the son of John Stewart, the younger, of Traquair in Peeblesshire, of a branch, originally illegitimate, of the house of Buchan, and was created Baron Stewart of Traquair in 1628 and earl of Traquair in 1633. He was appointed treasurer depute of Scotland and an extraordinary lord of session in 1630, and is said to have given the casting vote against the second Lord Balmerino at his trial in 1634, but afterwards obtained his pardon. From 1636 to 1641 he held the office of lord high treasurer of Scotland, and aided Charles I. in introducing the liturgy. He endeavoured to prevent a conflict by impressing on the king the necessity of caution and the danger of extreme measures against the rioters. He was, however, compelled to publish Charles's proclamation enforcing the use of the liturgy and forbidding hostile demonstrations on pain of treason (1638). This was followed by military measures in which Traquair assisted by secretly conveying munitions of war to Dalkeith Palace. He was, however, obliged to surrender the place with the regalia to the Covenanters (March 1639). After the treaty of Berwick he was appointed the king's commissioner to the assembly at Edinburgh (August 1639), and he assented in writing to the act abolishing episcopacy, but prevented its ratification by adjourning the opening of parliament. His apparent double-dealing made him suspected by both parties, and in 1641 the Scottish parliament issued a warrant for his arrest. In his absence he was sentenced to death, but, although the king secured the remission of this penalty, he was dismissed from his office of treasurer, and in 1644, for repairing to the court and opposing the covenant, he was declared an enemy to religion and fined 40,000 marks. His son, Lord Linton, whom he had sent to Montrose with a troop of horse, withdrew on the eve of the battle of Philiphaugh (September 1645) and it has been supposed that Traquair betrayed Montrose's plans to Leslie. He was readmitted to parliament in 1646, raised cavalry for the "engagement" between the king and the Covenanters, and was captured at Preston (1648). He was released by Cromwell in 1654, and died on the 27th of March 1659. He was succeeded by his only son John (*c.* 1622–1666), whose descendants held the title until 1861, when on the death of Charles, the 8th earl, it became dormant or extinct.

TRASIMENE, LAKE (Lat. *Trasumenus Lacus*; Ital. *Lago Trasimeno*), a lake of Umbria, Italy, 12 m. W. from Perugia, 843 ft. above sea-level, 30 m. in circumference, and

8 m. to 14 m. across. Having no natural outlet, it was formerly subject to sudden rises, which occasioned inundations, and these in turn malaria. An artificial outlet was completed in 1898 from the south-east corner of the lake to the Caina, a small tributary of the Tiber. The work, which is about 4 m. long, cost only about £26,000. It is intended to leave about 2500 acres of land dry, and to convert another 2800 acres of marshy soil into cultivable land. The lake contains three small islands: Isola Maggiore, with a monastery, Isola Minore and Isola Polvese. Standing on a promontory jutting out into the lake is the town of Castiglione del Lago, which possesses a castle of the dukes of Cornia, built by Galeazzo Alessi, the architect of many of the Genoese palaces. Napoleon I. formed a project for draining the lake, which may ultimately be adopted. Here Hannibal disastrously defeated the consul C. Flaminius. Hannibal left his winter quarters in Cisalpine Gaul in the spring of 217 B.C. and crossed the Apennines, probably by the pass now known as the Passo dei Mandrioli (from Forlì to Bibbiena in the upper valley of the Arno). His march was much hindered by marshes (probably those in the Arno valley between Bibbiena and Arezzo). The Roman army under Flaminius was stationed at Arezzo (anc. *Arretium*), and Hannibal marched past it. Flaminius followed, and Hannibal occupied the heights on the north of the lake between Terontola and Tuoro, commanding the road from Cortona to Perugia, and also those on the east of Tuoro, so that when the Roman army (which had encamped the night before outside the entrance to the small valley of the brook now called Sanguineto, west of Tuoro), unable in the mists of early morning to see the enemy's forces, had entered the valley, it was surrounded and there was no escape except by forcing a passage. The vanguard succeeded in making their egress on the east by Passignano, but the defeat of the rest of the army was complete, the Romans losing no fewer than 15,000 men.

See T. Ashby in *Journal of Philology* (1908), and refs. (T. As.)

TRASS, the local name of a volcanic tuff occurring in the Eifel, where it is worked for hydraulic mortar. It is a grey or cream-coloured fragmental rock, largely composed of pumiceous dust, and may be regarded as a trachytic tuff. It much resembles the Italian puzzolana and is applied to like purposes. Mixed with lime and sand, or with Portland cement, it is extensively employed for hydraulic work, especially in Holland; whilst the compact varieties have been used as a building material and as a fire-stone in ovens. Trass was formerly worked extensively in the Brohl valley and is now obtained from the valley of the Nette, near Andernach.

TRAÛ (Serbo-Croatian *Trogir*; Lat. *Tragurium*), a seaport of Dalmatia, Austria. Pop. (1900) of town and commune, 17,064. Traû is situated 16 m. W. of Spalato by road, on an islet in the Traû channel, and is connected with the mainland and the adjoining island of Bua by two bridges. The city walls are intact on the north, where a 15th-century fort, the Castel Camerlengo, overlooks the sea. Above the main gateway the lion of St Mark is carved, and the general aspect of Traû is Venetian. Its streets, which are too narrow for wheeled traffic, contain many interesting churches and medieval houses, including the birthplace of the historian Giovanni Lucio (Lucius of Traû), author of *De regno Dalmatiae et Croatiae* (Amsterdam, 1666). The loggia, built by the Venetians, is a fine specimen of a 16th-century court of justice; and the cathedral is a basilica of rare beauty, founded in 1200 and completed about 1450. It was thus mainly built during the period of Hungarian supremacy; and, in consequence, its architecture shows clear signs of German influence. Among the treasures preserved in the sacristy are several interesting examples of ancient jewellers' work. Traû has some trade in wine and fruit. It is a steamship station, with an indifferent harbour.

Tragurium was probably colonized about 380 B.C. by Syracusan Greeks from Lissa, and its name is sometimes derived from *Troghilon* a place near Syracuse. Constantine Porphyrogenitus writing in the 10th century, regards it as a corruption of *ἀγγύριον*, water melon, from a fancied similarity in shape. He states that Traû was one of the few Dalmatian cities which preserved its Roman character. In 998 it submitted to Venice; but in 1105 it acknowledged the supremacy of Hungary, while retaining its municipal freedom, and receiving, in 1108, a charter which is quoted by Lucio. After being plundered by the Saracens in 1123, it was ruled for brief periods by Byzantium, Hungary and Venice. In 1242 the Tatars pursued King Béla IV. of Hungary to Traû, but were unable to storm the island city. After 1420, when the sovereignty of Venice was finally established, Traû played no conspicuous part in Dalmatian history.

See T. G. Jackson, *Dalmatia, the Quarnero, and Istria* (Oxford, 1887); E. A. Freeman, *Sketches from the Subject and Neighbour Lands of Venice* (London, 1881); and G. Lucio, *Memorie istoriche di Tragurio, ora detto Traû* (Venice, 1673).

TRAUN, OTTO FERDINAND, COUNT VON ABENSPERG UND (1677–1748), Austrian field marshal, came of a noble family and was born on the 27th of August 1677 at Oldenburg. He was sent to Halle to complete his education, but in 1693 left the university to serve with the Prussian contingent of the allied army in the Low Countries. He saw much service in the War of the Grand Alliance, and at its close entered the imperial army. The War of the Spanish Succession soon followed, and Traun served with distinction in Italy and on the Rhine till 1709, when he became lieutenant-colonel and aide-de-camp to Field Marshal Count Guido Starhemberg (1654–1737) in Spain. A year later, for specially distinguished services, he was made colonel, and in 1712 chief of a regiment of foot. Soon after the close of the war he was again actively employed, and at the action of Francavilla in Sicily (June 20, 1719) he received a severe wound. For his services in this campaign in southern Italy he was promoted General-Feldwachtmeister in 1723. In 1727 he became governor of Messina, and in 1733 attained the rank of lieutenant field marshal. In 1734 he won a European reputation by his defence first of the pass of S. Germano and then of the half-ruined fortress of Capua, which he surrendered, marching out with the honours of war on the 30th of November. He was at once promoted Feldzeugmeister and employed in a difficult semi-political command in Hungary, after which he was made commander-in-chief in north Italy and interim governor-general of the Milanese, in which capacity he received the homage of the army and civil authorities on the accession of Maria Theresa in 1740. In the following year he was made a field-marshal. The Italian campaigns of the War of the Austrian Succession were successfully conducted by him up to 1743, when, on the death of Field-Marshal Count Khevenhüller (*q.v.*), he was made the principal military adviser of Prince Charles of Lorraine (*q.v.*), who commanded the Austrians in Bohemia and on the Danube. In this capacity he inspired the brilliant operations which led up to the passage of the Rhine (see AUSTRIAN SUCCESSION, WAR OF THE) and the skilful strategy whereby Frederick of Prussia was forced to evacuate Bohemia and Moravia (1744) without a battle. Traun's last active service was the command of an army which was sent to Frankfurt to influence the election of a new emperor to succeed Charles VII. He died at Hermannstadt on the 18th of February 1748.

TRAUNSTEIN, a town and summer resort of Bavaria, situated, at an elevation of nearly 2000 ft., on the river Traun, 73 m. by rail S.E. of Munich. Pop. (1905), 7447. It distils salt from the brine of Reichenhall, whence (22 m. distant) it is brought in pipes. It has an historical museum, four churches (three of which are Roman Catholic), two fine fountains—a monument of the war of 1870–71 and one to King Maximilian II. There are saline baths and breweries. In the vicinity are Empfing, with baths of all kinds and a cold-water cure establishment on the Kneipp system. Traunstein received civic rights in 1375.

TRAUTENAU (Czech *Trutňov*), a town of Bohemia, 120 m. E.N.E. of Prague by rail. Pop. (1900), 14,777, mostly German. It is situated on the Aupa, a tributary of the Elbe, at the foot of the Riesengebirge, and possesses a beautiful church built in 1283 and restored in 1768. Trautenau is the centre of the Bohemian linen industry and has factories for the manufacture of paper and for the utilization of the waste products of the other mills. Trautenau was founded by German colonists invited to settle there by King Otto Kar II. of Bohemia, and received a charter as a town in 1340. It was the scene of two battles between the Prussians and Austrians on the 27th and the 28th of June 1866.

TRAVANCORE, a state of southern India, in political relation with Madras. Area, 7091 sq. m. In 1901 the population was 2,952,157, showing an increase of 15% in the preceding decade. The state stands sixteenth among the native states of India in area and third in population. Travancore extends more than 150 m. along the west coast as far as Cape Comorin, the southernmost point of the peninsula. The Western Ghats rise to an elevation of 8000 ft. and are clothed with primeval forest; they throw out spurs towards the coast, along which there is a belt of flat country of about 10 m. in width, covered with coco-nut and areca palms, which to a great extent constitute the wealth of the country. The whole surface is undulating, and presents a series of hills and valleys traversed from east to west by many rivers, the floods of which, arrested by the peculiar action of the Arabian Sea, spread themselves out into lagoons or backwaters, connected here and there by artificial canals, and forming an inland line of smooth-water communication for nearly the whole length of the coast. The chief river is the Periyar, 142 m. in length. Other important rivers are the Pambai and its tributary the Achenkoil, the Kallada, and the Western Tambraparni. Iron is abundant and plumbago is worked. Elephants are numerous, and tigers, leopards, bears, bison and various kinds of deer abound in the forests. Travancore has an abundant rainfall, with every variety of temperature. The principal ports are Alleppi, Quilon and Paravur; but there is no real harbour. The state has a fine system of roads, and the Cochin-Shoranur and the Tinnevelly-Quilon railways pass through it. The Periyar irrigation project conducts water through the ghats in a tunnel to irrigate the Madras district of Madura, for which compensation of Rs. 40,000 is annually paid to Travancore. Trade is large and increasing, the chief exports being copra, coir and other coco-nut products, pepper, tea, sugar, areca-nuts, timber, hides, coffee, &c. The capital is Trivandrum. The revenue is £670,000; tribute, £80,000; military force, 1360 infantry, 61 cavalry and 30 artillery with 6 guns. The maharaja of Travancore claims descent from Cheraman Perumal, the last Hindu monarch of united Malabar, whose date is variously given from A.D. 378 to 825. Though he is a Kshatriya, the succession follows the local custom of inheritance through females; consequently his *sanad* of adoption authorizes him to adopt sisters' sons. For some generations the rulers have been men of education and character, and the state is conspicuous for good administration and prosperity. Education, and female education in particular, is more advanced than in any other part of India. The two dominant sections of the population are the Namburi Brahmins and the Nairs or military caste. Native Christians, chiefly of the Syrian rite, form nearly one-fourth of the whole, being more numerous than in any Madras district.

See V. Nagam Aiya, *Travancore State Manual* (Trivandrum, 1906).

TRAVE, a river of north Germany, rising in the Oldenburg principality of Lübeck, between Eutin and Ahrensböck. Flowing at first southwards through small lakes and marshes, it then turns west and, confined within flat and sandy banks, enters the Prussian province of Schleswig-Holstein. It now bends due south to Oldesloe, from which point it is navigable. Hence it takes an easterly course, and, entering the territory of the free city of Lübeck, receives from the right the Stecknitz, through which and the Stecknitz canal built by the merchants of Lübeck in 1398) a direct water communication is maintained with the Elbe, and passing the city of Lübeck discharges itself into the Baltic at the port of Travemünde after a course of 58 m. Its lower course from Lübeck to the sea has been dredged to a depth of 25 ft., permitting sea-going vessels to lie alongside the wharves and quays.

TRAVELLER'S TREE, a remarkable tree, native of Madagascar and Réunion, with a straight stem reaching 30 ft. in height and bearing at the top a number of large long-stalked leaves which spread vertically like a fan. The leaf has a large sheath at the base in which water collects in such quantity as to yield a copious draught—hence the popular name. The plant is known botanically as *Rarenala Madagascariensis* and belongs to the same family as the banana (Musaceae).

TRAVEMÜNDE, a seaport of Germany, in the free state of Lübeck, situated on the Baltic, at the mouth of the Trave. Pop. (1905), 2017. It has an Evangelical church, dating from the end of the 15th century, and is a much frequented watering-place. There are extensive herring fisheries. Travemünde arose out of a stronghold placed here by Henry the Lion, duke of Saxony, in the 12th century to guard the mouth of the Trave, and the Danes subsequently strengthened it. It became a town in 1317 and in 1329 passed into the possession of the free city of Lübeck, to which it has since belonged. Its fortifications were demolished in 1807.

TRAVERSE, in fortification, a mass of earth or other material employed to protect troops against enfilade. It is constructed at right angles to the parapet manned by the defenders, and is continued sufficiently far to the rear to give the protection required by the circumstances, which, moreover, determine its height. A traverse is sometimes utilized as a casemate. Ordinary field-works, not less than those of more solid construction, require traversing, though if the trenches, instead of being continuous, are broken into short lengths, they are traversed by the unbroken earth intervening between each length. (For traversing in surveying see SURVEYING.)

TRAVERSE CITY, the county-seat of Grand Traverse county, Michigan, U.S.A., on the Boardman river, between Boardman Lake and the west arm of Grand Traverse Bay, in the N.W. part of the lower peninsula. Pop. (1900), 9407, of whom 2068 were foreign-born; (1910, census), 12,115. It is served by the Père Marquette, the Grand Rapids & Indiana and the Manistee & North-Eastern railways, and by steamboat line to Chicago and other lake ports. The climate, scenery and good fishing attract summer visitors. The city has a public library and a library owned by the Ladies' Library Association, and is the seat of the Northern Michigan Asylum for the Insane (opened 1885). There are various manufactures, and in 1904 the total value of the factory product was $2,176,903. Traverse City was settled in 1847, incorporated as a village in 1881 and chartered as a city in 1895.

TRAVESTY (Fr. *travestie*, from *travestir*, to disguise, *se travestir*, to change one's clothes; Lat. *trans*, across, and *vestire*, to clothe), a burlesque, particularly a grotesque imitation of a serious work of literature or art, in which the subject, characters, &c., are retained, but the style, language and treatment generally are exaggerated and distorted to excite ridicule (see also BURLESQUE).

TRAVNIK, the capital of a department of the same name in Bosnia; situated on the Lašva, a left-hand tributary of the Bosna, 44 m. by rail N.W. of Serajevo. Pop. (1895) about 6000. Travnik is mainly built round a steep mass of rock, crowned by an ancient citadel. Several mosques, palaces, arcades and a fine bazaar, left among its narrow lanes and wooden huts, bear witness to its former prosperity, and there are some good modern barracks and public buildings.

The old name of Travnik, *Lašva*, was last used in the 18th century. It is likely, from the number of Roman remains, that Travnik stands near the site of a Roman colony. It was a stronghold of the Bogomili during the 15th century, but its period of greatness dated from 1686, when the downfall of the Turks in Hungary caused the removal of the Bosnian government from Banjaluka, which was dangerously near the Hungarian frontier, and the Turkish governors, officially styled "valis of Hungary," ruled in Travnik from 1686 to 1850.

Several interesting villages, none containing more than a few hundred inhabitants, are grouped together, near Travnik. Prozor, with its ruined citadel, which withstood the Turkish advance until the beginning of the 16th century, when almost the whole of Bosnia had been enslaved, was then the capital of the princes of Rama, a district lying north-west of the Narenta. The thermal station of Kiseljak, where the Fojnica and Lepenica rivers meet, is a cluster of old-fashioned Turkish villas, with a casino, baths, barracks, hotels and park. In 1396, Tvrtko I. of Bosnia granted the privilege of silver-mining here to the Ragusans. Remains of old workings may still be seen. Kreševo, 5 m. N.N.E., is likewise rich in iron, cinnabar, quicksilver and the argentiferous load which was worked by the Saxons in the middle ages. The citadel of Zahor, or Gradina, now a ruin, guarded the mines. Bugojno, on the Vrbas, is a picturesque place, with a large cattle and horse trade. The Franciscan monastery of Fojnica, 18 m. east, is the largest and wealthiest foundation in Bosnia. Its Byzantine church is full of ancient ornaments and relics. The archives contain many valuable manuscripts, including a charter bestowed on the monks, in 1463 by the Sultan Mahomet II.

TRAWLING, SEINING AND NETTING. The innumerable kinds of fishing nets which may be distinguished, if all nets differing in details of structure or use be placed in separate classes, fall naturally into two main groups, namely stationary nets and nets used in motion. The former group contains the most primitive nets, though nets of great complexity are now included in it; and the simplest fixed nets, themselves derived probably from dams of rushes or stones so placed as to lead fish in to a "pound" or enclosure, may with some confidence be considered as the ancestors of the great otter trawls now shot and towed daily from powerful steamers on fishing grounds more than a thousand miles from the market they work to supply. The more primitive fixed nets are of far less importance than movable nets (except in the capture of certain particular species), owing to the fact that they are necessarily confined to very shallow water. The main types of movable nets may therefore be treated first.

All nets are constructed in accordance with what is known of the habits of the fish they are designed to capture; and as fishes may be roughly divided into those spending at least the greater part of their lives on or near the sea-bottom and those spending a great portion of their lives near the surface, two lines have been followed in the development of nets, some being designed to work on the bottom, others to work near the surface. The most important nets used in the capture of "demersal" or bottom-living fishes are trawls; the most important pelagic nets are drift-nets. The word trawling[1] was at one time applied to more than one method of fishing, but has, at all events in Europe, now become restricted to the operation of a flattened conical net or trawl, dragged along the sea-bottom. There are two trawls in common use, the beam trawl and the otter trawl. They differ in the method adopted for extending the mouth of the net. The original form is the beam trawl.

The Beam Trawl. The beam trawl may be described as a flattened conical net whose mouth is kept open when in use by a long beam supported at the ends by iron runners, the trawl-heads. Elm is generally preferred for the beam, selected if possible from timber grown just to the proper thickness, that the natural strength of the wood may not be lessened by more trimming or chipping than is absolutely necessary. If the required length and thickness cannot be obtained in one piece, two or even three pieces are scarfed together, and the joints secured by iron bands. The trawl-heads differ somewhat in form in different countries and in different localities. The usual form is heart-shaped, the "shoe" or part actually in contact with the ground when in use being straight, the after-side straight and sloping upwards from the hindmost point or "heel," and then curving down in a single unbroken arc, which forms the front of the head, to join the shoe. In the Barking pattern the head is stirrup-shaped; but this is now unusual. A square socket is bolted to the top of the head (taking the head to be in the position of use) to receive the end of the beam, and ring-bolts are put in at the extreme front of each head, to hold the ropes or wires by which the trawl is towed, and, within the point of the heel, for the purpose of allowing the mouth of the net to be seized or lashed to the trawl-head at a point close to the ground. The shoe of the trawl-head is in the full-sized trawls made of double thickness, to resist wear.

The Net. When the net is spread out in the position it would take up when working, the upper part or back has its straight front edge fastened to the beam, but the corresponding lower part or belly is cut away in such a manner that the front margin forms a deep curve extending from the shoe of one trawl-head to that of the other, the centre of the curve or "bosom," as it is called, being at a considerable distance behind the beam. The usual rule in English trawls is for the distance between the beam and the centre of the bosom to be about the same as the length of the beam. In French trawls this distance is generally much less; but in all cases the beam and back of the net must pass over a considerable space of ground when the trawl is at work before the fish are disturbed by much of the lower margin of the net. This lower edge of the mouth of the trawl is fastened to and protected by the "ground-rope," which is made of an old hawser "rounded" or covered with small rope to keep it from chafing, and to make it heavier. The ends of the ground-rope are fastened at each side by a few turns round the back of the trawl-heads, just above the shoe, and the rope itself rests on the ground throughout its entire curve. The fish which may be disturbed by it have therefore no chance of escape at either the sides or top of the net unless they can pass through the meshes, and as the outlet under the beam is a long way past them, and is steadily moving on, sooner or later they mostly pass over the ground-rope and find their way into the funnel-shaped end of the net, from which a small valve of netting prevents their return.

It must not be supposed, of course, that all fishes entering a trawl are retained in it. Numerous investigations have been made into the size and number of the various species of fish which get through the meshes of the trawl, by lacing small-meshed netting over the ordinary net, and examining the fish remaining in this outer net. Fish are found to escape all parts of the net, but chiefly the "batings," *i.e.* the part of the net where it is narrowing to the "cod end"; and as the chance of escape depends on the size and shape of the fish, and the mesh of the net, it is naturally found that the maximum size of the individuals which can escape in any numbers differs in different species. If small fish are on the ground, the total number escaping is, however, in all cases very large, frequently greatly exceeding the number caught. This is for the most part desirable, the fish being of a size to render them of but little value to the fishermen or to the public. It is in any case inevitable, since a full-sized trawl made entirely of small-mesh would offer so great a resistance to the water as to be unworkable.

The ground-rope bears directly on the ground, and to prevent the possibility of the fish passing under it, the rope should have some weight in it so as to "bite" well, or press the ground closely. It is, however, always made of old material, so that it may break in case of getting foul of rocks or such other chance obstruction as may be met with on the generally smooth ground where the trawl can only be worked with advantage. If in such a contingency the rope were so strong and good as not to break, there would be serious danger of the tow-rope snapping, and then the whole apparatus might be lost; but the ground-rope giving way enables the net to be cleared and hauled up with probably no more damage to it than the broken rope and perhaps some torn netting. The remaining part of the trawl, extending from the bosom to the extreme end, forms a complete bag gradually diminishing in breadth to within about the last 10 ft., which part is called the "cod or purse," and is closed by a draw-rope or "cod-line" at the extremity when the net is being used. To avoid the abrasion of the under part of the cod-end pressed by the weight of fish against the stones and shells of the sea-bottom, stout pieces of old net are laced across beneath it in parallel strips. These strips thus trail beneath the trawl and protect it. They constitute the "rubbers" or "false belly." The cod-end is the general receptacle for the various fishes which enter the net; and when the trawl is hauled up and got on board the vessel, the draw-rope is cast off and the fish all fall out on the deck.

Pockets. It has been mentioned that the body of the net tapers away to the entrance to the purse. It is at this point the opening of the pockets are placed; and they are so arranged that the fish having passed into the purse, and then seeking to escape by returning along its sides, are pretty sure to go into the pockets, which extend for a length of about 15 or 16 ft. along the inner side of the body of the net, and there, the more they try to press forward, the more tightly they become packed, as the pockets gradually narrow away to nothing at their upper or front extremity. These pockets are not separate parts of the trawl, but are made by merely lacing together the back and belly of the net, beginning close to the margin or side nearly on a level with the bosom, and then being carried on with slowly increasing breadth backward as far as the entrance to the purse. At this point the breadth of the net is divided into three nearly equal spaces, the central one being the opening from the main body of the net into the purse, or general receptacle for the fish, which must all pass through it, and those on each side being the mouths of the pockets facing the opposite direction. The central

[1] "Trawl" is from O. Fr. *trauler*, to go hither and thither; "troll," now used of drawing a line along the surface of the water from a boat, is from the variant O. Fr. *troller*, mod. *trôler*, to lead, drag about.

passage has a valve or veil of netting called the "flapper," which only opens when the fish press against it on their way into the purse. To understand clearly the facilities offered to the fish to enter the pockets, it is necessary to remember that the trawl, when at work, is towed along, with just sufficient force to expand the net by the resistance of the water. But this resistance directly acts only on the interior of the body of the net between the pockets and then on the purse; it does not at first expand the pockets, but tends rather to flatten them, because they are virtually outside the general cavity of the trawl and their openings face the father end of it. The water, however, which has expanded the body of the net, then passes under or through the flapper or valve, and enters the purse, which, being with a much smaller mesh than the rest of the net, offers so much resistance that it cannot readily escape in that direction; return currents are consequently formed along the sides, and those currents open the mouths of the pockets, which, as before mentioned, are facing them; and the fish, in their endeavours to escape, and finding these openings, follow the course of the pockets until they can go no farther. The whole of the net is therefore well expanded, but it is so by the pressure of the water in one direction through the middle, and in the opposite direction at the sides or pockets.

Size and Mesh.

The dimensions of a full-sized beam trawl, such as has been described above are from 45 to 50 ft. along the beam and about 100 ft. in length. Trawls of practically all smaller sizes down to some 30 ft. are to be found, but except for shrimp trawls the large sizes predominate almost to the exclusion of smaller nets. The trawl-heads support the beam at about 3 or 3½ ft. above the ground. The meshes of the net behind the beam (the square) are about 5 in. from knot to knot, when drawn out taut. In the batings, the part of the net in which the narrowing mostly occurs, they decrease gradually from 4 to about 3 in.; in cod end they are 2½ in. In the hope of protecting the small fish from capture some local authorities enforce within their jurisdiction a minimum size of mesh for trawls, as for other nets. According to certain recent by-laws of the Lancashire and Western Sea Fisheries District Committee, for instance, every trawl used in their waters, except for the capture of shrimps and certain specified fish, must allow a square wooden gauge of a certain size to pass easily through its meshes when these are wet. The difficulties in the way of the efficacy of such restriction are that a mesh which would allow the escape of fish of but little value of one species might allow the escape of very valuable individuals of another kind; and that both local and national authorities alike have powers of jurisdiction over such narrow strips of coastal water, that in the absence of an international agreement on the matter, the ground affected by the regulations is exceedingly small in comparison with the ground untouched. The same remarks apply to the similar regulations as to length of beam and circumference of nets.

Working the Net.

Considerable skill is needed to work a beam trawl successfully. A knowledge of the ground and of the direction and time of the tide is essential; for the trawl is towed with the stream, a little faster than it is running, so that there may be just sufficient resistance to expand the net. The regulation of speed, seeing that beam trawls are worked only from sailing vessels, is a matter of difficulty; when, however, there is a sufficiency of wind much can be done by an adjustment of the length of tow rope. Lowering the trawl is also a matter of difficulty especially when wind and tide are contrary, as in that case the vessel tends to drift over the net: the apparatus is first got into position by paying out the rope attached to the trawl-heads in such proportions that the beam takes its proper position while close to the surface. These ropes, called "bridles," are some 15 fathoms long: they meet and are shackled to the trawl warp, a manilla rope of 6 in. circumference, of which 150 fathoms are generally carried. The trawl being in proper position, the warp is allowed to run out and the trawl lowered to the bottom, the vessel slowly moving on meanwhile; usually the length of warp which is below the surface in towing is a few fathoms over three times the depth of water. The art of shooting the trawl lies in causing it to alight on its runners or shoes, with the net freely trailing behind: should the net be twisted, or the trawl alight on its beam, the trawl has been shot "foul," and must be hauled and shot again. While towing, an experienced fisherman can tell by pressing his hand firmly on the warp outside the ship's bulwark whether the progress of the trawl over the bottom is satisfactory, any irregular progress over rough ground revealing itself in the character of the vibration of the warp.

The trawl usually remains on the bottom for a whole tide, or six hours, and will in this time have passed over some 15 m. of ground. Hauling, a most lengthy and laborious process if carried out by hand-windlass, is in practically all modern fishing smacks carried out by a small steam capstan, the "steam man" as it is frequently called, a most efficient instrument with very compact engine housed under a small iron cover on the capstan's top. When the trawl comes alongside the heavy beam is secured by its two heads, the net is hauled over the side bit by bit, by hand, until the cod end is reached, when a rope is passed round it above the bulging end which contains the catch, and then over a "tackle" or pulley, and so the cod end is hoisted inboard. The knot of the cod-line is untied, and the fish, mixed with various invertebrate animals, star-fish and rooted forms (confounded in the one term "scruff"), falls to the deck.

Shrimp Trawls.

A small trawl is often used from an open boat for shrimping. It closely resembles a beam trawl, but has no pockets. The usual dimensions of this net are about 15 ft. beam and 20 total length, of which about 4 ft. are taken by the cod end. The mesh is about half an inch square, but where no restrictions are enforced it decreases to a considerably smaller size as the cod end is approached. The beam when in use is about a foot and a half above the ground.

Shank Nets.

Shank nets are also similar to beam trawls in general shape, but differ in that the mouth is kept open by a rectangle of wood. Frequently the lower margin of the trawl's mouth is not in contact with the ground, being attached to a bar of wood which is fixed parallel to the bottom of the wooden rectangle and a few inches above it. A fish or prawn is thus disturbed by the bottom bar of the wood, and either jumps over it and *below* the net and so escapes, or over both bottom bar and middle bar *into* the net. The theory of the net's action is that the fish tends most frequently to take the former course, the crustacean the latter; and there is some evidence that this is partially realized in practice. Shank nets are sometimes worked from carts, when they are known as "Trollopers."

Owing to their fine netting and the very shallow water in which they work, shrimp trawls are exceedingly destructive to very small fish. Johnstone[1] has found for instance that in a two mile haul of a shrimp trawl on the Lancashire coast 567 small plaice are caught on an average, beside great numbers of whiting, dabs, soles and other fish. In most parts of the English coast regulations are in force as to the mesh, size of beam and length of haul of shrimp nets, and shrimpers working on the beach are ordered to sort their catch at the water's edge, returning as many young fish alive as possible. The proportion saved by these means is not known with accuracy; it is much greater in the case of short hauls than in longer ones. A shrimp trawl is usually kept down from half an hour to an hour, or when not subject to regulation rather longer. It is seldom towed for a longer period than 2 hours, the speed being somewhat under two miles per hour on an average, though subject to variation.

Decay of Beam Trawling and rise of other Trawling from Steamers.

The beam trawl has been described at some length because its structure is somewhat more simple than that of the trawl now in more general use; the importance of the net as an engine of capture has undoubtedly declined greatly within the past generation. Some interesting figures collected by the British Board of Agriculture and Fisheries prove this incontestably. In 1893 the number of first-class British sailing trawlers was 2037, and their average net tonnage 57·4; in 1900 they numbered 925, with a net tonnage of 41·1, and from that year up to 1906 (the last year quoted in these returns) they never again reached a thousand in number or a tonnage of 40 tons net; on the other hand, there were in no one of the years quoted as few as 800 first-class sailing trawlers registered, nor did the average tonnage sink below 37, about which figure it remained constant. It is obvious therefore that about 1894 beam trawling began to decline, and that after a time this decline lost most of its power, the number of boats and size of boats having sunk to a condition in which they fulfilled a certain function, which for some years has remained fixed. The new factors which brought about this change went hand in hand. They were the invention of the otter trawl and the increasing use of steam in fishing vessels. The otter trawl has no rigid and heavy beam, but relies on the force with which it is towed through the water to keep it open, and it is a far more efficient instrument for the capture of all but small flat fish than the beam trawl. Owing to the second of these facts its employment inevitably spread, and owing to the first a sailing vessel needing at least a moderate breeze to give it the requisite speed for keeping a large net open was unsuitable for working it. Thus the introduction of the otter trawl undoubtedly hastened the replacement of sails by steam as motive power for the great fishing fleets. That the adoption of steam would have occurred in any case is almost certain. The conversion of drift-net fishing vessels from sail to steam has gone on rapidly, though no radical change of gear has taken place, and presumably the same would have occurred in the case of trawlers had the otter trawl never have introduced. There

[1] Johnstone, *British Fisheries*, p. 283 (London, 1905).

were, for instance, nearly 200 steam fishing vessels of various descriptions working from English and Welsh ports in 1883; and the desire to exploit new and more distant grounds had undoubtedly become powerful by 1894, and accounted to some extent for the increase of steam trawling about that time. Nevertheless this increase is so sudden, that its occurrence at the time of the adoption of the otter trawl can scarcely be a coincidence. In 1893 there were 480 steam trawlers working from English and Welsh ports: in 1899 there were over a thousand.

The subsequent history of British trawling is dominated by the steamers. Garstang has calculated from a study of market statistics that a steamer (between the years 1889 and 1898) caught on the average between four and seven times as much in a year as a sailing smack. Against this competition the smacks could not succeed; if it was profitable for the steamers to fish they could gradually eliminate the smacks, as has occurred at Grimsby. The line fishery also decreased owing to the increasing transfer of the haddock and some other fisheries to the trawlers. The change from masts and sails to steam has, however, never been complete. The increased cost of building and running steamers made the handling of large catches a necessary condition of their profitable employment. A sailing trawler costs from £500 to £1200 to build: £1000 would probably be a fair average. A first-class steam trawler of the present day costs £10,000 or more, quite ten times as much, and about £5000 a year to run; and although the cost was less in the early years of steam trawling there was always an approach to these proportions. On the other hand their rapidity and independence of wind made distance between fishing ground and port of landing a matter of minor consequence. These causes, combined with a very general belief in the exhaustion of the home-grounds—there seems no doubt that at all events the catch per vessel declined—led to the growth in size and power of the steamers, which were used for distant waters and the exploitation of new grounds. Thus in 1906 there were only 200 more steam trawlers than in 1899, but the average tonnage in the same period increased from 54 to nearly 62. To this increase in power and range of action of the steamers must be attributed the great increase in the quantity of trawled fish landed, since the engine of capture, the trawl, has changed but little since 1894: but another result occurred, namely a partial division of the area trawled between sail and steam. The grounds within easy reach of the English ports were left chiefly in the hands of the "smacks," the catches never being really very great, though possessing a high proportion of "prime" (*i.e.* valuable species of) fish. The persistence of Lowestoft and Ramsgate as smack ports speak for this. The longer voyages of the smacks, on the other hand, were gradually discontinued, and the distant grounds besides a multitude of new grounds were opened up by the steamers. Grimsby, Hull, Aberdeen, Milford, increased enormously in importance, and now send vessels to the north of Russia, to the coast of Africa and far into the Atlantic. Steam trawling died at Yarmouth, the place of its birth; sailing trawlers disappeared from Grimsby, one of their greatest strongholds, but a port near cheap coal, deep water, and a market for fish from more distant grounds.

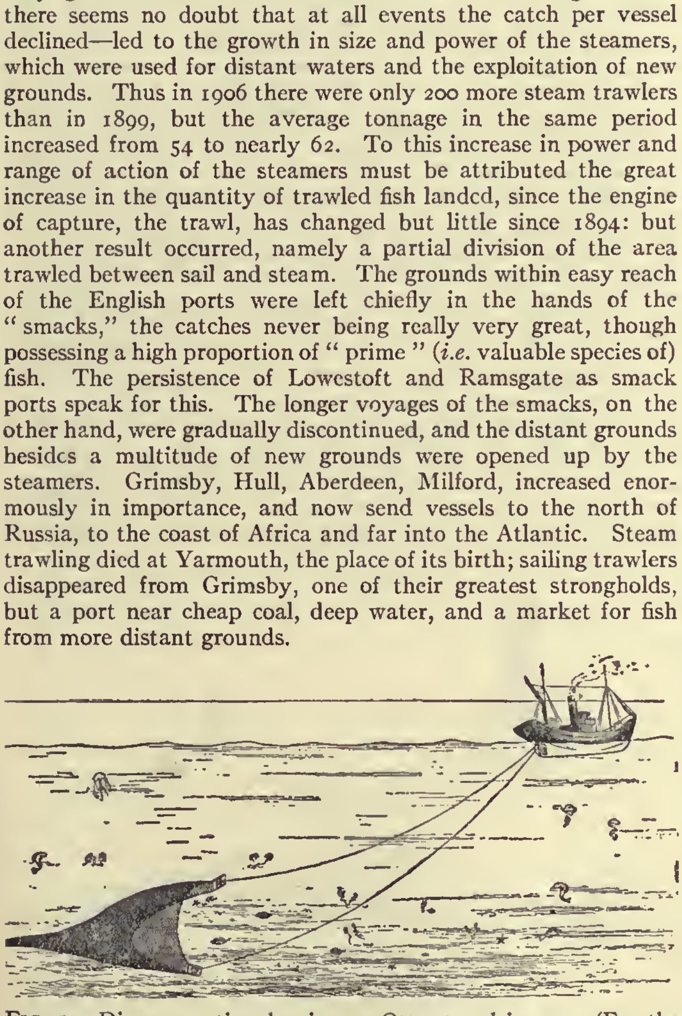

FIG. 1.—Diagrammatic; showing an Otter trawl in use. (For the sake of clearness, the size of the otter-boards is exaggerated, and the length of the warps and size of the ship diminished.)

The Otter Trawl. Principle of Action.

The essential features of the otter trawl are that the mouth is kept open by two large wooden boards, whose position when in use corresponds to that of the trawl heads in a beam trawl, no beam being used. The action of these boards resembles that of a kite. A kite dragged through still air, owing to the position of the point of attachment of the string, takes up an oblique position, in which it is acted on by forces in two directions, viz. that exerted through the string, pulling forward, and that exerted by the resistance of the air in front of the kite, which, being perpendicular to the kite's surface, acts in an upward and backward direction. The resultant of these two forces necessarily acts in a direction between them, and the kite accordingly ascends. Constrain the kite to move in a horizontal plane, and the same forces would cause it to move not upwards, but to the side. A trawl board is practically a kite made to move on its side.

The trawl boards resemble massive wooden doors strengthened by iron bands. In action they move with their short edges vertical and their long edges horizontal, one in each case in contact with the sea bottom: the front bottom corner of each board is rounded off, so that the board resembles a sleigh runner. Four strong chains, which meet in one iron ring, are attached to each board by ringbolts, and to each ring a wire warp, by which the trawl is towed, is shackled. The ringbolts are about the same distance from the centre of the board, but the two chains attached to the alter-ringbolts of the board are longer than the two fore-chains. The trawl board when towed thus takes up an oblique position as regards the line in which it is towed, though remaining vertical to the ground. The force with which it is towed urges it forward; the resistance of the water urges it in a direction perpendicular to its surface, viz. backwards and to the side; it accordingly moves in an intermediate direction, going forward by tending to diverge from the line of towing. Meanwhile the other trawl-board is diverging in a similar manner but in the opposite direction, and the mouth of the net, being attached to the hinder end of the boards, is thus pulled both right and left until stretched to its utmost, and the net is thus held open. The margin of the net which forms its upper lip is lashed to a rope called the headline: and the resistance of the water to the net's progress causes this to assume an arched form, the centre of the headline being probably some 10 or 15 ft. from the ground.

It has been calculated by Fulton, who experimented on the subject, that the distance between the boards of an otter trawl of 90 ft. headline is about 60 ft., owing to this arching upwards and backwards of the upper margin of the net. The loss in the spread of the net is, however, compensated for very largely, as far as certain round fish are concerned, by the increase in height of the mouth, the fish which are swimming near but not actually on the bottom tending to "strike upward" when disturbed. Indeed, the raising of the headline is accentuated occasionally by glass spheres or other buoyant objects to its centre; corks are still used in this way, but otherwise the practice has not been generally adopted in commercial trawling.

The earliest use of the otter board appears to have been due to Hearder, an electrician and inventor who designed it about 1860. It was little used except by amateurs working by steam yachts (to whom doubtless the ease with which it could be stowed away recommended it), until the late 'eighties, when Danish fishermen used otter boards to spread their plaice seines. In 1894 a patent was taken out by Scott of Granton for an otter trawl which differed from the most modern forms chiefly in possessing rigid bars or brackets instead of chains. Chains replaced the bars in the form used by Nielsen, a Dane, in 1895. Although numerous variants have since arisen, no essential difference in the trawl has been generally adopted.

Details of Structure. The Boards.

The trawl boards, or as they are frequently called "doors," are of deal, 8 to 9 ft. long, and 4 to 5 ft. high; they are liberally shod and strengthened with iron, and are about 3 in. thick. The net is fastened to eyes placed at the top and bottom of the after-end of the board, but not to any intermediate point. This is to allow the part of the water swirling past the board to escape: the entry of the whole of the water upon which the net's mouth advances would cause too great a resistance.

The Warps.

Two warps are used, one to each trawl board. These are composed of wire rope 2½ in. round, and when the trawl is inboard lie coiled up on the separate drums of a steam winch. As wire can be run off or wound in on either drum separately, the adjustment of the lengths is much simplified. In the larger trawlers a thousand fathoms of warp is carried on each drum, and the warp is designed to stand a breaking strain of 23 tons.

The Net.

The main form of net is that of the beam trawl. We have, as in that net, a coarse meshed netting used near the mouth, a decrease in size of mesh as the net narrows, and a bag or cod end whose end is fastened by a cod line passed through its final meshes. The only essential difference lies in the net behind the headline. This has not, as in the beam trawl, a straight margin, but a curved one, the pointed sides of the net being termed the "top wings" of the trawl, the corresponding parts of the bottom being in both trawls the bottom wings. The ground rope resembles that in the beam-trawl, but is in some cases furnished with chains or "dangles" or with "bobbins." Bobbins are heavy cylindrical wooden rollers, threaded on the wire warp which forms the core of the ground rope: they are of two sizes (the larger a foot through) placed alternately to ensure freedom of rotation. Their object is to surmount or crush obstacles which, by catching the ground rope, might capsize the trawl boards and destroy the success of the haul; they are accordingly used only on rough ground. The chains are fastened to the ground rope in loops, to give it weight, and are used on very soft ground to ensure the trawl's effectually dislodging the fish. The headline is a rope some 3 in. in circumference.

The meshes are, from knot to knot when drawn taut, from $5\frac{1}{2}$ to nearly 6 in. in the square and wings, 5 to $4\frac{1}{2}$ in. above, and 5 to rather over 3 in. below in the extreme back of the under batings called the "belly," about $2\frac{1}{2}$ in. in the cod end.

Working the Net. The successful shooting of the net is a matter of great skill. The paying out of the net, the lowering of the boards, the running out of unequal lengths of the two warps to square the trawl into proper position and the subsequent lowering of the whole to the bottom, resemble the corresponding operations with the beam trawl. The fore warp is then drawn close to the quarter of the vessel and shackled to the after-warp close to the vessel's side, and the vessel proceeds on her course at a speed of some $2\frac{1}{4}$ or $2\frac{1}{2}$ m. per hour. The length of haul made varies enormously. On a ground where fish is very abundant, as in the early days of Iceland fishing, it may be half an hour or less: on the Eastern Grounds, off Denmark, where the great English fleets usually work, it is about 3 hours. When about to haul, the fore warp is released from the shackle and the vessel is immediately steered towards the side from which the trawl has been towed, while the warps are rapidly wound in; the warps thus speedily come to stand at right angles to the vessel. If this were not the case they might probably foul the vessel's propeller, with very serious and possibly fatal consequences to her safety. The trawl boards, having been drawn right up to their powerful iron supports or gallows, remain suspended there if the trawl is to be re-shot while the net is emptied; they are otherwise lowered between the gallows and the bulwark, and secured. The hauling in of the catch occurs as in the beam-trawl. Trawlers carry a trawl on each side of the deck, and in continuous trawling these are worked alternately. On each side of the deck a square enclosure called a pound is made for the reception of the fish falling from the cod end, by fitting planks turned on their sides into stanchions grooved for their reception. The fish is sorted into baskets in the pound, cleaned and packed in trunks in ice in the hold or fish-room.

Fleet Fishing. A noteworthy method of trawling is the custom of 50 or 60 boats fishing together in a fleet. All these vessels will trawl as directed by an "admiral," in proximity to a "mark-boat," whose position is known to the owners from day to day, and the fish is daily fetched to market by fast "carriers." There are four such fleets of British vessels working in the North Sea. It is also worthy of mention that wireless telegraphy has recently been fitted to several German trawlers and drifters, which can thus communicate with the fishery protection cruisers, who pass on information concerning the fishery, and with the shore. The practice will doubtless spread, although as yet the distance over which a message can be sent by these vessels is very small.

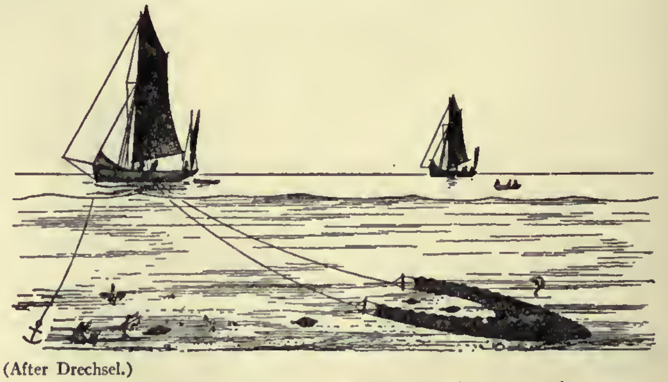
Depths worked. The use of steam has not only increased the radius of action of the vessel, but by facilitating the process of hauling enables trawling to be carried out in greater depths. The sailing vessels rarely work in greater depths than 30 fathoms. The steam vessels work frequently (*e.g.* south of Ireland) in over 200 fathoms. Commercial trawling in 500 fathoms is not unknown, and the Irish research vessel "Helga" works in as much as 800 fathoms.

Seines. The movable nets resembling trawls are seines, from which trawls were in all probability developed. The seine is an extremely ancient net, used by Phoenicians, Greeks and other Mediterranean peoples, the word seine being derived from the Greek name (σαγήνη) for the appliance. In essence it is a long strip of netting with a buoyed headline and weighted ground rope. It is taken out in a boat some little distance from the shore, paid out during the boat's progress, and the lines attached to the ends being then brought back to the shore, the net is hauled up on the beach. From this simple form, which is still in use for the capture of smelts and other small fish, numerous developments have occurred. Before mentioning the details of a few of the chief of these it may be said that the changes mainly consist in the formation of a purse or pocket in the middle of the net, somewhat resembling the cod end of a trawl, and in the working of the net from boats or ships instead of from the sea. The boat is anchored during the hauling, the net being drawn to it. A net with a wide spread, furnished with a purse, drawn over the sea bottom to a boat, is obviously very near a trawl in its action. When in the late 'eighties Danish fishermen fastened otter boards to their plaice-seines, and allowed the boat to drift, the seine was dragged *by*, not *to* the boat, and when Petersen used a similar arrangement, presently to be described, dragged like a trawl, the evolution of a trawl from a seine was practically complete. Some such process, with the use of a beam instead of otter boards, probably occurred in the past and resulted in the beam trawl.

Pilchard Seines. Pilchard seines, as the most elaborate forms of simple seines, may be briefly described. The pilchards approach certain parts of the Cornish coast, notably St Ives and Penzance, in shoals which are eagerly awaited; and when they are sufficiently near two boats start out on the fishery. One carries a short seine, the stop net, which has previously been joined to the large seine, and shoots this net as it rows towards shore. The other rows along the shore, shooting its net as it goes. Ultimately the boats turn to meet each other, and when they do so the ends of the long seine are joined, the stop net removed, and the circle of netting towed to the beach until its ground rope touches the bottom. The pilchards are then removed at leisure by a smaller seine called a tuck-net—seine being a word which in the west of England is confined to nets worked from the beach. This net is very deep in the middle, and as the foot rope is drawn well in in hauling, a floor is formed for it as it approaches the boat from which it is worked, a simple form of purse or bag resulting. The pilchards are dipped out in large baskets. In a good catch this process of "tucking" out the fish may be carried on for some days. The long seine used may be 200 fathoms long, and is about 6 fathoms deep at the ends and 8 fathoms in the middle. The tuck-net is about 80 fathoms long, 8 deep at the ends and 10 fathoms in the middle. The meshes are larger at the ends or wings than in the middle, as in the trawl, bringing a tuck-net from 30 down to 42 the yard.

Purse Seines. The seine is far more used in the United States than in the British Islands, its operations being so successful that complaints have in some cases been made that local fisheries for certain species have been entirely destroyed owing to the diminution of the fish which it has brought about. It is used in water of any depth, for the purpose of catching mackerel. Rings are fastened to the ground rope, and by means of a rope passed through these rings the lower margin of the net is drawn together, converting the circle of netting into a complete basin-shaped purse. The slack of the net is then gradually drawn in, the fish collecting in the last of the net (the fullness or "bunt") to be reached. Purse seines are also used in Japan, where there is also in use a net which is a combination of seine and pound-net. A long wall of netting forms a "leader" to the fish, and ends in an oval enclosure formed by a purse seine with incompletely closed ends. Two anchored boats, to which the seine is lashed, keep it extended. On hauling, the opening is closed and the slack of the net hauled into one boat, which approaches the other, until the final portion containing the fish is brought to the surface.

"Seines with Pockets." The pockets of seines, though answering the same purpose as those of trawls in preventing the escape of the fish, resemble not the pockets but the cod end of the latter net. In the *filets de bœuf* of the Mediterranean the pocket is a very long bag, trailing behind the arms of the seine, and constricted for some distance before joining it. It is without "flapper" or other valve.



(After Drechsel.)

FIG. 2.—Diagram of a Danish Plaice-seine at work.

Most efficient pocketed seines are used in Denmark for the capture of eels and plaice. In both these nets the depth increases rapidly as soon as the extreme wings are left, and is very great in the middle. Thus when in action but little of the net is vertical; the ground and head ropes, though not parallel, tend to become so, and the net trails in a curve behind them. Seen from above, the whole front margin of the net is semicircular, but the net itself is shaped like the hinder part of a trawl: in fact, did the headline of a trawl lie not in front but exactly over the ground rope, the two nets would be almost identical.

Danish Seines.

The eel drag-seine is worked from a boat, in shallow water. The extreme ends or wings are attached to two short spars, which in use are upright, and each of these is furnished with a line top and bottom which meet and are attached to the ropes by which the net is hauled in. The total length of the net is about 140 ft. from wing to wing, the length of the bag 30 ft., the depth at mouth is 20 ft. opening, the depth at the ends 6 or 8 ft.

Eel Drag-seine.

The eel drift-net resembles the preceding, but is not drawn to an anchored boat, but drifts with the boat; it has accordingly to be made much smaller, its arms being each about 24 ft.—or a total length of 50. The wings were sometimes kept apart by the use of a floating spar, to the ends of which the seine was attached by short ropes, the spar itself being towed. A funnel-shaped valve leads into the bag.

Eel Drift-net.

Petersen's trawl was designed by Dr Petersen for use in deep water, and for the capture of rapidly moving animals. It is essentially a drift-seine of the preceding pattern, worked with two small otter boards instead of a beam, and furnished with but a single warp, to which the otter boards are attached by shorter ropes or bridles. When used in very deep water these are prevented from twisting by attaching at the point of their junction with the warp a glass float and a leaden weight. This net is undoubtedly highly suitable for great depths. It is probably the "trawl" which it has been reported has been repeatedly used in the great depth of 2900 fathoms from the Norwegian research vessel "Michael Sars," in the course of the cruise in the Atlantic carried out in 1910 by Sir John Murray and Dr Hjort. It is practically a small otter trawl with the square cut out, leaving only wings, back part of batings and cod end, which last is entered by a funnel of netting. The meshes, in the net first constructed by Dr Petersen, were about a centimetre square in the wings and 8 millimetres square in the bag. The arms were each 24 ft. long, the bag about 16 ft. The boards were 29 in. by 32 in., and ¾ in. thick. Glass floats are frequently used with this trawl, to keep up the headline.

Petersen's Trawl.

The Danish plaice-seine resembles the eel-seine in form, but is much larger, each arm being about 180 ft. long; the bag is 20 ft. long. The drag lines are also much longer, sometimes reaching to 1200 fathoms. These nets are worked from a very large number of boats, Esbjerg being the chief North Sea port engaged in the fishery. The vessels are yawl rigged, of the size of all but the largest smacks, and each is now furnished with a motor-boat. The boat takes the net to a considerable distance from the parent vessel, which is anchored, and shoots it in a wide curve. The drag lines are then brought back to the smack for hauling. By this method plaice are captured alive, and are kept in large floating fish-boxes until required.

Danish Plaice-seine.

Next in importance to trawling among the English fisheries is the use of drift-nets for mackerel, herrings and pilchards. It is undoubtedly the most common method of net-fishing on the coasts of the British islands, but nowhere is it so general as in Scotland. There are, however, great drift fisheries on the eastern and southern coasts of England, and an important mackerel fishery mainly at the western end of the channel, though owing to a high import duty on mackerel levied by France this is now of far less importance. The value of the mode of fishing technically known as "drifting or driving" will be understood when it is remembered that it is the only method by which such fishes as herrings, mackerel and pilchards, which generally swim at or near the surface, can be readily caught in the open sea, at any distance from land, and in any depth of water, so long as there is sufficient for the floating of the nets in the proper position. The term "drift-net" is derived from the manner in which the nets are worked. They are neither fixed nor towed within any precise limits of water, but are cast out or "shot" at any distance from the land where there are signs of fish, and are allowed to drift in whichever direction the tide may happen to take them, until it is thought desirable to haul them in. The essential principle of the working of the drift-net is that it forms a long wall or barrier of netting hanging for a few fathoms perpendicularly in the water, but extending for a great length horizontally, and that the fish, meeting these nets and trying to pass them, become meshed; they force their heads and gill-covers through the meshes, but can go no farther; and as the gill-covers catch in the sides of the mesh, the fish are unable to withdraw and escape. Whether it be mackerel, herring or pilchard, the manner in which the net works is the same; the variations which exist relate only to the differences in habits and size of the fish sought after.

Drift Nets.

The nets used are light cotton nets, each about 30 yards long and 10 or 12 deep, and when designed for herring have a mesh of about an inch square, pilchard nets being smaller and mackerel nets larger in mesh. These nets are laced end to end in a long row, the whole row, called a "fleet" or "train" of nets being, in the case of the large herring boats, as much as 3½ miles long. One of the long edges of the net is fastened to a rope corked at regular intervals, whose purpose is to keep that part uppermost. This edge is called the "back" of the net. The corks are, however, not sufficient to keep the whole net from sinking, and this is done by buoys called "bowls," which are attached to the back rope at intervals. It is always a matter of uncertainty at what depth the fish may be found, and a deal of judgment is needed in deciding what length of rope should be used in attaching the buoys. In the herring fishery of the English east coast the British boats usually work in somewhat shallower water than the foreign drifters, and set their nets at about 4 fathoms from the surface, the foreigners, lying outside them, using deeper-set nets. It is found convenient to colour certain of the bowls distinctively to indicate their position in the "fleet." Otherwise they are coloured to show ownership.

Drift-net fishing is with rare exceptions only carried on at night. The time for beginning is just before sunset, and the nets are then got into the water by the time it is dark. A likely place to fish is known (though there is much uncertainty in the matter) by signs recognizable only to the practised eye. An obvious one is the presence of many sea-birds, or of the fish themselves. But besides these the appearance and even the smell of the water furnishes a guide. In the case of the mackerel these signs have been shown by G. E. Bullen (*Journ. Marine Biol. Assoc.* viii. 269) to be due to the character of the microscopic organisms in the water, some of which furnish the food of the mackerel, others of which it avoids. If fish is believed to be present the vessel is sailed slowly before the wind and if possible across the tide; then the net is shot or thrown out over the vessel's quarter, the men being distributed at regular stations, some hauling up the net from below, others throwing it over and taking care that it falls so that the foot is clear of the corked back; others, again, looking after the warp which has to be paid out at the same time, and seeing that the seizings are made fast to it in their proper places. When it is all overboard, and about 15 or 20 fathoms of extra warp, called the "swing-rope," given out, the vessel is brought round head to wind by the warp being carried to the bow; the sails are then taken in, the mast lowered, a small mizen set to keep the vessel with her head to the wind, and the regulation lights are hoisted to show that she is fishing. A few of the hands remain on deck to keep a look out, and the vessel and nets are left to drift wherever the wind and tide may take them. It is very rarely that there is an absolute calm at sea; and if there is the faintest breath of air stirring the fishing boat will of course feel it more than the buoys supporting the nets; she will consequently drift faster, and being at the end of the train, extend the whole fleet of nets. In rough weather, as the strain may be greater, more rope is used. The first net in the train is often hauled after an hour to enable the men to judge whether the position is a good one. When the whole are hauled, the nets are taken in and the fish shaken out in the same orderly way as in shooting, each man having his own proper duty.

The sailing drifter is fast disappearing, giving place to the steam drifter. These vessels, though costing far more (£2500 to £3000 against £400 only) catch more fish, have a greater radius of action, reach market more quickly and are independent of weather. It has been calculated that a thousand square feet of herring netting used by a steamer catch 43½ cwt. of herring, while a sailing vessel catches 20 cwt. with the same area of netting; and the steamer-caught fish, being more quickly delivered, fetches a better price. It may be noted that of recent years herring have been caught at the bottom in considerable quantities by the trawl. The fishing of herring is thus increasing in variety of method, as well as in intensity. Such sailing boats as tend to remain are long shore boats, and such drifters as have been fitted with petrol motors.

Stationary nets, being of very small importance relatively to the preceding, must be dismissed more shortly. They are of four main kinds, viz.: stake nets, pound and kettle nets, stow and bag nets, trammel-nets and hose nets.

Stationary Nets.

Stake nets are usually set between tide-marks, or in shallow water, and, as their name implies, are kept up by stakes placed at intervals. They are generally set across the direction of the tide. They act as gill nets, and are chiefly used in America. In some cases a conical bag instead of a flat net occupies the space between every two stakes, forming a series of simple bag nets. This form is used on the German shores of the North Sea.

Stake Nets.

In another modification the net is supported on the stakes, which is some 200 ft. long, does not act as a gill net but as a "leader," and one of its ends passes through a narrow opening into a circular enclosure surrounded by a similar wall of staked netting. The bag net and fly net for the capture of the salmon are merely elaborated forms of this type. The pound is roofed by netting, in the fly net, and in the bag net, which is floated—not staked—floored also. It is wedge-shaped, narrowing gradually from the entrance end, and divided incompletely by oblique internal walls or valves of netting into side compartments.

Pound and Kettle Nets.
